

# Irreducible decomposition for local representations of quantum Teichmüller space

Jérémy Toulisse

April 22, 2014

## Abstract

We give an irreducible decomposition of the so-called local representations [HBL07] of the quantum Teichmüller space  $\mathcal{T}_q(\Sigma)$  where  $\Sigma$  is a punctured surface of genus  $g > 0$  and  $q$  is a  $N$ -th root of unity with  $N$  odd.

Let  $\Sigma$  be an oriented surface of genus  $g > 0$  with  $s$  punctures  $v_1, \dots, v_s$  such that  $2g - 2 + s > 0$  (this condition is equivalent to the existence of an ideal triangulation of  $\Sigma$ , ie. a triangulation whose vertices are exactly the  $v_i$ ). Let  $\mathcal{T}(\Sigma)$  be the Teichmüller space of  $\Sigma$ , that is the moduli space of complete hyperbolic metrics on  $\Sigma$ . Given  $\lambda$  an ideal triangulation of  $\Sigma$ , W.P. Thurston [Thu98] constructed a parameterization of  $\mathcal{T}(\Sigma)$  by associating a strictly positive real number to each edge  $\lambda_i$  of the ideal triangulation,  $i \in \{1, \dots, n\}$  (where  $n = 6g - 6 + 3s$  is the number of edges of  $\lambda$ ). These coordinates are called **shear coordinates** associated to  $\lambda$ . In this coordinates system, the coefficients of the Weil-Petersson form on  $\mathcal{T}(\Sigma)$  depend only on the combinatoric of  $\lambda$  and are easy to compute.

For a parameter  $q \in \mathbb{C}^*$ , L.O. Chekhov, V.V. Fock [FC99] and independently R. Kashaev [Kas98] defined the so-called **quantum Teichmüller space**  $\mathcal{T}_q(\Sigma)$  of  $\Sigma$  (the construction of R. Kashaev differs a little from the one of L.O. Chekhov and V.V. Fock), which is a deformation of the Poisson algebra of rational functions over  $\mathcal{T}(\Sigma)$ . This algebraic object is obtained by gluing together a collection of non-commutative algebra  $\mathcal{T}_q(\lambda)$  (called Chekhov-Fock algebra) canonically associated to each ideal triangulation of  $\Sigma$ . A representation of  $\mathcal{T}_q(\Sigma)$  is then a family of representation  $\{\rho_\lambda : \mathcal{T}_q(\lambda) \rightarrow \text{End}(V)\}_{\lambda \in \Lambda(\Sigma)}$ , where  $\Lambda(\Sigma)$  is the space of all ideal triangulations of  $\Sigma$ , and  $\rho_\lambda$  and  $\rho_{\lambda'}$  satisfy compatibility conditions whenever  $\lambda \neq \lambda'$ . For  $\lambda \in \Lambda(\Sigma)$ , the representation  $\rho_\lambda$  is an avatar of the representation of  $\mathcal{T}_q(\Sigma)$  and carries almost all the information.

When  $q$  is a  $N$ -th root of unity,  $\mathcal{T}_q(\lambda)$  admits finite-dimensional representations. In this paper, we will consider  $N$  odd. The irreducible representations of  $\mathcal{T}_q(\lambda)$  have been studied in [BL07]. In particular, they show that an irreducible representation of  $\mathcal{T}_q(\lambda)$  is classified (up to isomorphism) by a weight  $x_i \in \mathbb{C}^*$  assigned to each edge  $\lambda_i$ , a choice of  $N$ -th root  $p_j = (x_1^{k_{j1}} \dots x_n^{k_{jn}})^{1/N}$  associated to each puncture  $v_j$  (where  $k_{ji}$  is the number of times a small simple loop around

arXiv:1404.4938v1 [math.GT] 19 Apr 2014

$v_j$  intersects  $\lambda_i$ ) and a square root  $c = (p_0 \dots p_s)^{1/2}$ . Such a representation has dimension  $N^{3g-3+s}$ .

In [HBL07], the authors introduced another type of representations of  $\mathcal{T}_q(\lambda)$ , called **local representations**, which are well behaved under cut and paste. A local representation of  $\mathcal{T}_q(\lambda)$  is defined by an embedding into the tensorial product of **triangle algebras** (see definitions below). The local representations of  $\mathcal{T}_q(\lambda)$  are classified (up to isomorphism) by a weight  $x_i \in \mathbb{C}^*$  associated to each edge  $\lambda_i$  and a choice of  $N$ -th root  $c = (x_1 \dots x_n)^{1/N}$ . Such a representation has dimension  $N^{4g-4+2s}$ .

It follows that a local representation of  $\mathcal{T}_q(\lambda)$  is not irreducible. In this paper, we address the question of the decomposition of a local representation into its irreducible components. In particular, we prove the following result:

**Theorem 1.** *Let  $\lambda$  be an ideal triangulation of  $\Sigma$  and  $\rho$  be a local representation of  $\mathcal{T}_q(\lambda)$  classified by weight  $x_j \in \mathbb{C}^*$  associated to each edge  $\lambda_j$  and a choice of  $N$ -th root  $c = (x_1 \dots x_n)^{1/N}$ . We have the following decomposition:*

$$\rho = \bigoplus_{i \in \mathcal{I}} \rho^{(i)}.$$

Here,  $\rho^{(i)}$  is an irreducible representation classified by the same  $x_j$ , a  $N$ -th root  $p_j^{(i)} = (x_1^{k_{j_1}} \dots x_n^{k_{j_n}})^{1/N}$  associated to each puncture, and the same  $c$ . Moreover, for each choice of  $N$ -th root  $p_j = (x_1^{k_{j_1}} \dots x_n^{k_{j_n}})^{1/N}$  for each puncture and  $c = (p_0 \dots p_s)^{1/2}$ , there exists exactly  $N^g$  elements  $i \in \mathcal{I}$  with  $p_j^{(i)} = p_j$  for all  $j \in \{0, \dots, s\}$ .

This result may be used to define representations of the so-called **Kauffman skein algebra**  $\mathcal{S}^A(\overline{\Sigma})$  [Tur91] (where  $\overline{\Sigma}$  is the surface  $\Sigma$  without marked points) which corresponds to a quantization by deformation of the character variety

$$\mathcal{R} := \text{Hom}(\pi_1(\overline{\Sigma}), PSL(2, \mathbb{C})) // PSL(2, \mathbb{C})$$

where  $PSL(2, \mathbb{C})$  acts by conjugation on the morphisms and the double slash means that we take the quotient in the sense of Geometric Invariant Theory. In [BW11, Theorem 1], the authors constructed a morphism

$$Tr_\omega(\lambda) : \mathcal{S}_A(\Sigma) \longrightarrow \hat{\mathcal{Z}}_\omega(\lambda),$$

where  $q = \omega^4$ ,  $A = \omega^{-2}$  and  $\hat{\mathcal{Z}}_\omega(\lambda)$  is an algebra of non-commutative rational fractions such that  $\mathcal{T}_q(\lambda)$  consists of rational fractions in  $\hat{\mathcal{Z}}_\omega(\lambda)$  involving only even powers of the variables. This morphism, composed with a representation  $\rho$  of  $\mathcal{T}_q(\lambda)$  is studied in [BW12a] and [BW12b] to define a new kind of representations of  $\mathcal{S}^A(\Sigma)$ . However, if one wants to define representation of  $\mathcal{S}^A(\overline{\Sigma})$  in the same way, one has to consider the direct sum of  $N^g$  irreducible components of a local representation  $\rho : \mathcal{T}^q(\lambda) \rightarrow \text{End}(V)$  arising in the decomposition of Theorem 1 and find a subspace  $E \subset V$  stable by  $\rho \circ Tr_\omega(\lambda)$  such that  $(\rho \circ Tr_\omega(\lambda))|_E$  defines a representation of  $\mathcal{S}^A(\overline{\Sigma})$  (see [BW14] for the construction). Hopefully, this representation of  $\mathcal{S}^A(\overline{\Sigma})$  should be used to define a more intrinsic version of

the Kashaev-Baseilhac-Benedetti TQFT (see [Kas95], [Kas99], [BB04], [BB05] and [BB07]).

In the first section, we recall the definition of the Chekhov-Fock algebra, the quantum Teichmüller space, the triangle algebra and the local representations. In the second one, we prove the Theorem 1. The proof is done in two steps: we first prove the result for a special triangulation  $\lambda_0$  and special weights; we then extend to the general case.

**Acknowledgment :** I would like to thank Francis Bonahon for the time he spent explaining me the subtleties of the quantum Teichmüller theory. This work has been supported by a "Summer Regs" grant from GEAR in summer 2013.

## 1 The Chekhov-Fock algebra and the irreducible representations of $\mathcal{T}_q(\Sigma)$

The results of this section come from [BL07] and [HBL07]. From now, for  $n \in \mathbb{N}$ , define  $\mathbb{N}_n := \mathbb{Z}/n\mathbb{Z}$  and denote by  $\mathcal{U}(N)$  the group of  $N$ -th root of unity.

### 1.1 The Chekhov-Fock algebra

Let  $\lambda$  be an ideal triangulation of  $\Sigma$ . The **Chekhov-Fock algebra**  $\mathcal{T}_q(\lambda)$  associated to  $\lambda$  is the algebra generated by the elements  $X_i^{\pm 1}$  associated to each edge  $\lambda_i$  of the triangulation  $\lambda$ . These elements are subjects to the relations:

$$X_i X_j = q^{\sigma_{ij}} X_j X_i,$$

where the coefficients  $\sigma_{ij}$  are the coefficients of the Weil-Petersson form in the shear coordinates associated to  $\lambda$  and depend only on the combinatoric of  $\lambda$ . Namely, we have  $\sigma_{ij} = a_{ij} - a_{ji}$  where  $a_{ij}$  is the number of angular sector delimited by  $\lambda_i$  and  $\lambda_j$  in the faces of  $\lambda$  with  $\lambda_i$  coming before  $\lambda_j$  counterclockwise. In practice, elements of  $\mathcal{T}_q(\lambda)$  are just Laurent polynomials in the variables  $X_i$  satisfying non-commutativity conditions. We will sometimes denote  $\mathcal{T}_q(\lambda)$  by  $\mathbb{C}[X_1^{\pm 1}, \dots, X_n^{\pm 1}]_q$  to reflect this fact.

Let  $\mathbf{k} = (k_1, \dots, k_n) \in \mathbb{Z}^n$  be a multi-index; to a monomial  $X$  composed of a product of  $X_i^{k_i}$ , we associate its quantum ordering:

$$[X] := q^{-\sum_{i < j} \sigma_{ij} k_i} X_1^{k_1} \dots X_n^{k_n}.$$

It allows us to associate a monomial  $X_{\mathbf{k}} \in \mathcal{T}_q(\lambda)$  to each multi-index  $\mathbf{k} \in \mathbb{Z}^n$ .

To study finite-dimensional representations of  $\mathcal{T}_q(\lambda)$ , one needs to determine its center.

**Proposition 1** ([BL07], Proposition 15). *The center of  $\mathcal{T}_q(\lambda)$  is generated by:*

- $X_i^N$  for each  $i \in \{1, \dots, n\}$ .
- For each puncture  $v_j$ , the **puncture invariant**  $P_j$  associated to the multi-index  $\mathbf{k}_j = (k_{j_1}, \dots, k_{j_n})$  (where  $k_{j_i}$  is the number of intersections of  $\lambda_i$  with a small simple loop around  $v_j$ ).

- The element  $H$  associated to the multi index  $\mathbf{k} = (1, \dots, 1)$ .

Note that  $[P_1 \dots P_s] = H^2$ .

## 1.2 Triangle algebra

Let  $T$  be a disk with three punctures  $v_1, v_2, v_3 \in \partial T$  endowed with the natural triangulation  $\lambda$  composed of three counterclockwise directed edges  $\lambda_1, \lambda_2$  and  $\lambda_3$  (as in Figure 1).

Figure 1: The triangle  $T$

Define the **triangle algebra** as the Chekhov-Fock algebra  $\mathcal{T} := \mathcal{T}_q(\lambda)$ . It is generated by  $X_1^{\pm 1}, X_2^{\pm 1}, X_3^{\pm 1}$  with relations  $X_i X_{i+1} = q^2 X_{i+1} X_i$  for all  $i \in \mathbb{N}_3$ . The center of  $\mathcal{T}$  is given by  $X_1^N, X_2^N, X_3^N$  and  $H = q^{-1} X_1 X_2 X_3$ . Irreducible finite dimensional representations of  $\mathcal{T}$  have dimension  $N$  and are classified (up to isomorphism) by a choice of weight  $x_i \in \mathbb{C}^*$  associated to each edge  $\lambda_i$  and a central charge, that is a choice of a  $N$ -th root  $c = (x_1 x_2 x_3)^{1/N}$  (see [HBL07, Lemma 2]).

To be more precise, for  $V$  the  $N$ -dimensional complex vector space generated by  $\{e_1, \dots, e_N\}$  and  $\rho$  an irreducible representation of  $\mathcal{T}$  classified by  $x_1, x_2, x_3 \in \mathbb{C}^*$  and  $c = (x_1 x_2 x_3)^{1/N}$ . Up to isomorphism, the action of  $\mathcal{T}$  on  $V$  defined by  $\rho$  is given by:

$$\begin{cases} X_1 e_i = \tilde{x}_1 q^{2i} e_i \\ X_2 e_i = \tilde{x}_2 e_{i+1} \\ X_3 e_i = \tilde{x}_3 q^{1-2i} e_{i-1} \end{cases}$$

where  $\tilde{x}_i$  is an  $N$ -th root of  $x_i$  such that  $\tilde{x}_1 \tilde{x}_2 \tilde{x}_3 = c$ . Note that, up to isomorphism,  $\rho$  is independent of the choice of the  $N$ -th root  $\tilde{x}_i$  with  $\tilde{x}_1 \tilde{x}_2 \tilde{x}_3 = c$ .

In particular, for the representation  $\rho$  classified by  $x_1 = x_2 = x_3 = 1$  and  $c \in \mathcal{U}(N)$ , as  $\rho(X_i)^N = Id_V$ , the spectrum of  $\rho(X_i)$  is a subset of  $\mathcal{U}(N)$ . For  $h \in \mathcal{U}(N)$ , denote by  $V_h(X_i)$  the eigenspace of  $\rho(X_i)$  associated to the eigenvalue  $h$ . We have the following lemma which will be useful in the next section:

**Lemma 1.** For each  $i \in \{1, 2, 3\}$  and  $h \in \mathcal{U}(N)$ ,  $\dim(V_h(X_i)) = 1$ .

*Proof.* We use the explicit form of the representation  $\rho$  in  $V = \text{span}\{e_1, \dots, e_N\}$ . Take  $\tilde{x}_1 = \tilde{x}_2 = 1$  and  $\tilde{x}_3 = c$ .

For  $i = 1$ , one sees that  $V_h(X_1) = \text{span}\{e_k\}$  where  $h = q^{2k}$ .

For  $i = 2$ , the vector  $\alpha_k := \sum_{i \in \mathbb{N}_N} q^{-2ki} e_i$  satisfies  $X_2 \alpha_k = q^{2k} \alpha_k$  and  $\{\alpha_1, \dots, \alpha_k\}$  form a basis of  $V$ . Then  $V_h(X_2)$  is generated by  $\alpha_k$ .

For  $i = 3$ , we use the fact that  $X_1 X_2 X_3 e_i = c e_i$ , where  $c$ , the central charge of  $\rho$ , lies in  $\mathcal{U}(N)$ .  $\square$

### 1.3 Local representation of $\mathcal{T}_q(\lambda)$

Let  $\lambda$  be an ideal triangulation of  $\Sigma$ . Such a triangulation is composed of  $m$  faces  $T_1, \dots, T_m$  and each face  $T_j$  determines a triangle algebra  $\mathcal{T}_j$  whose generators are associated to the three edges of  $T_j$ . It provides a canonical embedding  $\mathfrak{i}$  of  $\mathcal{T}_q(\lambda)$  into  $\mathcal{T}_1 \otimes \dots \otimes \mathcal{T}_m$  defined on the generators as follow:

- $\mathfrak{i}(X_i) = X_{ji} \otimes X_{ki}$  if  $\lambda_i$  belongs to two distinct triangles  $T_j$  and  $T_k$  and  $X_{ji} \in \mathcal{T}_j$ ,  $X_{ki} \in \mathcal{T}_k$  are the generators associated to the edge  $\lambda_i \in T_j$  and  $\lambda_i \in T_k$  respectively.
- $\mathfrak{i}(X_i) = [X_{ji_1} X_{ji_2}]$  if  $\lambda_i$  corresponds to two sides of the same face  $T_j$  and  $X_{ji_1}, X_{ji_2} \in \mathcal{T}_j$  are the associated generators.

Now, a local representation of  $\mathcal{T}_q(\lambda)$  is a representation which factorizes as  $(\rho_1 \otimes \dots \otimes \rho_m) \circ \mathfrak{i}$  where  $\rho_i : \mathcal{T}_i \rightarrow V_i$  is an irreducible representation of the triangle algebra  $\mathcal{T}_i$ . In particular, such a representation has dimension  $N^m$  where  $m = 4g - 4 + 2s$  is the number of faces of the triangulation.

### 1.4 Classification of these representations

Here we recall [BL07, Theorem 21] and [HBL07, Proposition 6] respectively:

**Theorem 2.** (*F. Bonahon, X. Liu*) *An irreducible representation of  $\mathcal{T}_q(\lambda)$  is determined by its restriction to the center of  $\mathcal{T}_q(\lambda)$  and is classified by a non-zero complex number  $x_i$  associated to each edges  $\lambda_i$ , for each puncture  $v_j$ , a choice of a  $N$ -th root  $p_j = (x_1^{k_{j1}} \dots x_n^{k_{jn}})^{1/N}$  and a choice of a square root  $c = (p_0 \dots p_s)^{1/2}$ .*

*Such a representation satisfies:*

- $\rho(X_i^N) = x_i Id$ ,
- $\rho(P_j) = p_j Id$ ,
- $\rho(H) = c Id$ .

**Theorem 3.** (*H. Bai, F. Bonahon, X. Liu*) *Up to isomorphism, a local representation of  $\mathcal{T}_q(\lambda)$  is classified by a non-zero complex number  $x_i$  associated to the edge  $\lambda_i$  and a choice of a  $N$ -th root  $c = (x_1 \dots x_n)^{1/N}$ . Such a representation satisfies:*

- $\rho(X_i^N) = x_i Id$ ,
- $\rho(H) = c Id$ .

## 1.5 The quantum Teichmüller spaces and its representations

If one wants to quantize the Teichmüller space, he has to do it in a canonical way. The definition of the Chekhov-Fock algebra  $\mathcal{T}_q(\lambda)$  involves the choice of an ideal triangulation. So we have to understand the behavior when one changes from an ideal triangulation  $\lambda$  to another one  $\lambda'$ . Set  $\mathcal{T}_q(\lambda) = \mathbb{C}[X_1^{\pm 1}, \dots, X_n^{\pm 1}]_q$  and  $\mathcal{T}_q(\lambda') = \mathbb{C}[X_1'^{\pm 1}, \dots, X_n'^{\pm 1}]_q$ . These algebras admit a division algebras, denoted by  $\hat{\mathcal{T}}_q(\lambda)$  and  $\hat{\mathcal{T}}_q(\lambda')$  respectively, consisting of rational fractions in the variables  $X_i$  (respectively  $X_i'$ ) satisfying some non-commutativity relations.

For each pair of ideal triangulation  $\lambda$  and  $\lambda'$ , L.O. Chekhov and V.V. Fock constructed coordinates change isomorphisms

$$\Psi_{\lambda\lambda'}^q : \hat{\mathcal{T}}_q(\lambda') \longrightarrow \hat{\mathcal{T}}_q(\lambda),$$

which are the unique isomorphism satisfying naturals conditions (as for example  $\Psi_{\lambda\lambda''}^q = \Psi_{\lambda\lambda'}^q \circ \Psi_{\lambda'\lambda''}^q$  for each  $\lambda, \lambda'$  and  $\lambda''$  ideal triangulations of  $\Sigma$ ). See [Liu09] for more details and explicit formulae of  $\Psi_{\lambda\lambda'}^q$ .

Now, the **quantum Teichmüller space**  $\mathcal{T}_q(\Sigma)$  is defined by:

$$\mathcal{T}_q(\Sigma) := \bigsqcup_{\lambda \in \Lambda(\Sigma)} \hat{\mathcal{T}}_q(\lambda) / \sim,$$

where  $\Lambda(\Sigma)$  is the set of ideal triangulation of  $\Sigma$ , and the equivalence relation  $\sim$  identifies each pair of  $\hat{\mathcal{T}}_q(\lambda)$  and  $\hat{\mathcal{T}}_q(\lambda')$  by the isomorphism  $\Psi_{\lambda\lambda'}^q$ . Note that, as each coordinates change  $\Psi_{\lambda\lambda'}^q$  is an algebra isomorphism,  $\mathcal{T}_q(\Sigma)$  inherits an algebra structure, and the  $\hat{\mathcal{T}}_q(\lambda)$  can be thought as "global coordinates" on  $\mathcal{T}_q(\Sigma)$ .

A natural definition for a finite dimensional representation of  $\mathcal{T}_q(\Sigma)$  would be a family of finite dimensional representation  $\{\rho_\lambda : \hat{\mathcal{T}}_q(\lambda) \longrightarrow \text{End}(V_\lambda)\}_{\lambda \in \Lambda(\Sigma)}$  such that for each pair of ideal triangulation  $\lambda$  and  $\lambda'$ ,  $\rho_{\lambda'}$  is isomorphic to  $\rho_\lambda \circ \Psi_{\lambda\lambda'}^q$ . Note that, as pointed out in [HBL07, Section 4.2], there exists no algebra homomorphism  $\rho_\lambda : \hat{\mathcal{T}}_q(\lambda) \longrightarrow \text{End}(V_\lambda)$  for  $V_\lambda$  finite dimensional. In fact, as  $\hat{\mathcal{T}}_q(\lambda)$  is infinite dimensional as a vector space and  $\text{End}(V_\lambda)$  is finite dimensional, such a homomorphism  $\rho_\lambda$  would have non-zero kernel. Hence, there would exist elements  $x \in \hat{\mathcal{T}}_q(\lambda)$  such that  $\rho_\lambda(x) = 0$  and so,  $\rho_\lambda(x^{-1})$  would make no sense.

So one defines a **local representation (respectively irreducible representation) of  $\mathcal{T}_q(\Sigma)$**  as a family of representation  $\{\rho_\lambda : \mathcal{T}_q(\lambda) \longrightarrow \text{End}(V_\lambda)\}_{\lambda \in \Lambda(\Sigma)}$  such that for each  $\lambda, \lambda' \in \Lambda(\Sigma)$ ,  $\rho_\lambda$  is a local representation (respectively irreducible representation) of  $\mathcal{T}_q(\lambda)$ , and  $\rho_{\lambda'}$  is isomorphic (as representation) to  $\rho_\lambda \circ \Psi_{\lambda\lambda'}^q$  whenever  $\rho_\lambda \circ \Psi_{\lambda\lambda'}^q$  makes sense. We say that  $\rho_\lambda \circ \Psi_{\lambda\lambda'}^q$  makes sense, if for each Laurent polynomial  $X' \in \mathcal{T}_q(\lambda')$ , there exists  $P, P', Q$  and  $Q' \in \mathcal{T}_q(\lambda)$  such that:

$$\Psi_{\lambda\lambda'}(X') = PQ^{-1} = Q'^{-1}P' \in \hat{\mathcal{T}}_q(\lambda);$$

now, as  $\rho_\lambda(\mathcal{T}_q(\lambda)) \subset GL(V_\lambda)$ ,  $\rho_\lambda(Q)$  and  $\rho_\lambda(Q')$  are invertibles, so we can define:

$$\rho_\lambda \circ \Psi_{\lambda\lambda'}(X') := \rho_\lambda(P)\rho_\lambda(Q)^{-1} = \rho_\lambda(Q')^{-1}\rho_\lambda(P').$$

A fundamental result in [BL07] and [HBL07, Proposition 10] is that for each pair of ideal triangulations  $\lambda$  and  $\lambda'$ , there exists a rational map

$$\varphi_{\lambda\lambda'} : \mathbb{C}^n \longrightarrow \mathbb{C}^n$$

such that a local representation  $\rho_{\lambda'}$  of  $\mathcal{T}_q(\lambda')$  classified by  $x'_i \in \mathbb{C}^*$  associated to  $\lambda'_i$  and  $c' = (x'_1 \dots x'_n)^{1/N}$  is isomorphic to  $\rho_\lambda \circ \Psi_{\lambda\lambda'}$  (whenever it makes sense) for a representation  $\rho_\lambda$  of  $\mathcal{T}_q(\lambda)$  classified by  $x_i \in \mathbb{C}^*$  associated to  $\lambda_i$  and  $c = (x_1 \dots x_n)^{1/N}$  if and only if  $c = c'$  and

$$(x'_1, \dots, x'_n) = \varphi_{\lambda\lambda'}(x_1, \dots, x_n).$$

## 2 Proof of Theorem 1

### 2.1 Special case

Here we prove Theorem 1 for a local representation  $\rho : \mathcal{T}_q(\lambda_0) \longrightarrow \text{End}(V)$  where  $\lambda_0$  is special triangulation of  $\Sigma$  and  $\rho$  is classified by weights  $x_i = 1$  and  $c \in \mathcal{U}(N)$ . Here,  $\Sigma$  is a genus  $g > 0$  surface with  $s + 1$  punctures  $v_0, \dots, v_s$ . Recall that  $m = 4g - 4 + 2(s + 1)$  and  $n = 6g - 6 + 3(s + 1)$  are respectively the number of faces and edges of  $\lambda_0$ . Moreover, we denote by  $Xu$  the action of  $X \in \mathcal{T}_q(\lambda_0)$  on  $u \in V$  defined by  $\rho$ .

To decompose  $\rho$  into irreducible factors, one has to look at the eigenspaces of  $\rho(P_j)$  for each puncture invariant  $P_j$  associated to the puncture  $v_j$ . Note that, as  $\rho(P_j)^N = \text{Id}$ , the spectrum of  $P_j$  is contained in  $\mathcal{U}(N)$ .

The idea of the proof is to look at the action of the  $P_j$  on each factor of a nice decomposition of  $V$  into a tensorial product of vector spaces. It is based on the following remark:

**Remark 1.** *For a decomposition  $V = E_1 \otimes E_2$ , if  $x_j \in E_j$  satisfies  $Px_j = h_j x_j$  for  $j = 1, 2$  where  $P \in \{P_0, \dots, P_s\}$  and  $h_j \in \mathcal{U}(N)$ , then  $P(x_1 \otimes x_2) = h_1 h_2 x_1 \otimes x_2$ . That is, the eigenspace of  $P$  in  $V$  associated to the eigenvalue  $h \in \mathcal{U}(N)$  contains the tensorial product of eigenspaces of  $P$  in  $E_j$  associated to the eigenvalues  $h_j$ , for  $j = 1, 2$ , whenever  $h = h_1 h_2$ .*

For  $\mathbf{h} = (h_1, \dots, h_s) \in \mathcal{U}(N)^s$ , set

$$V_{\mathbf{h}} := \{u \in V, P_i u = h_i u, i = 1, \dots, s\}.$$

**Proposition 2.** *For each  $\mathbf{h} \in \mathcal{U}(N)^s$ ,  $\dim V_{\mathbf{h}} = N^{m-s}$ .*

*Proof.* Take an ideal triangulation  $\tilde{\lambda}$  of  $\Sigma \setminus \{v_1, \dots, v_s\}$  (which is a one punctured surface), and for a triangle  $T$  of  $\tilde{\lambda}$ , consider the triangulation of  $T \cup \{v_1, \dots, v_s\}$  as in Picture 2.

The union of these two triangulations gives an ideal triangulation  $\lambda_0$  of  $\Sigma$ . Denote by  $\tilde{V}$  the tensorial product of all the vector spaces associated to the triangles of  $\tilde{\lambda} \setminus T$ . As the triangulation  $\tilde{\lambda}$  contains  $3g - 1$  triangles,  $\dim(\tilde{V}) = N^{3g-2}$  (because we do not consider the vector space associated to  $T$ ). Denote by  $V^j$  and  $V^{k^{\text{th}}}$  the  $j^{\text{th}}$  (resp.  $k^{\text{th}}$ ) vector space associated to the triangle  $T_j$  (resp.  $T'_k$ ) as in Figure 2 (here,  $j \in \{0, \dots, s\}$  and  $k \in \{1, \dots, s\}$ ).

For  $\mathbf{h} = (h_1, \dots, h_s) \in \mathcal{U}(N)^s$  and  $j \in \{1, \dots, s\}$ , define:

Figure 2: Triangulation of  $T \cup \{v_1, \dots, v_s\}$

- .  $\mathcal{V}_{\mathbf{h}}^j = \{x \in V^j \otimes V'^j, P_k x = h_k x, k = 1, \dots, s\}$ .
- .  $\mathcal{V}_{\mathbf{h}}^0 = \{x \in V^0, P_k x = h_k x, k = 1, \dots, s\}$ .

We have the following lemma:

**Lemma 2.**

- i.  $\dim \mathcal{V}_{\mathbf{h}}^0 = \begin{cases} 1 & \text{if } h_k = 1 \ \forall k \neq 1 \\ 0 & \text{otherwise.} \end{cases}$
- ii.  $\forall j \in \{1, \dots, s-1\} \dim \mathcal{V}_{\mathbf{h}}^j = \begin{cases} 1 & \text{if } h_k = 1 \ \forall k \notin \{j, j+1\} \\ 0 & \text{otherwise.} \end{cases}$
- iii.  $\dim \mathcal{V}_{\mathbf{h}}^s = \begin{cases} N & \text{if } h_k = 1 \ \forall k \neq s \\ 0 & \text{otherwise.} \end{cases}$

*Proof.* i. If  $k \neq 1$ ,  $v_k$  is not a vertex of  $T_0$ . It follows that  $P_k$  acts on  $V^0$  by the identity; so if  $h_k \neq 1$ ,  $\mathcal{V}_{\mathbf{h}}^0 = \{0\}$ .

Now, if  $h_k = 1$  for all  $k \neq 1$ , then  $\mathcal{V}_{\mathbf{h}}^0 = V_{h_1}^0(P_1)$  (as defined in Lemma 1) which is one dimensional.

ii. Fix  $j \in \{1, \dots, s-1\}$ . For  $k \notin \{j, j+1\}$ ,  $v_k$  is neither a vertex of  $T_j$  nor of  $T'_j$ . So  $P_j$  acts on  $V^j \otimes V'^j$  as the identity. Hence, if  $h_k \neq 1$ , then  $\mathcal{V}_{\mathbf{h}}^j = \{0\}$ .

Take  $h_k = 1$  for all  $k \notin \{j, j+1\}$  and denote by  $\mathcal{T}_j = \mathbb{C}[X^{\pm 1}, Y^{\pm 1}, Z^{\pm 1}]_q$ ,  $\mathcal{T}'_j = \mathbb{C}[X'^{\pm 1}, Y'^{\pm 1}, Z'^{\pm 1}]_q$  the triangle algebras associated to the triangles  $T_j$  and  $T'_j$  respectively (as in Figure 3).

Figure 3: The generators of  $\mathcal{T}_j$  and  $\mathcal{T}'_j$

For  $c_j, c'_j \in \mathcal{U}(N)$  the central charges of the restriction of the representation to  $\mathcal{T}_j$  and  $\mathcal{T}'_j$  respectively,  $P_j$  acts on  $V^j := \text{span}\{e_0, \dots, e_{N-1}\}$  like  $c_j Z^{-1}$ , on  $V'^j = \text{span}\{e'_0, \dots, e'_{N-1}\}$  like  $c'_j Z'^{-1}$  and  $P_{j+1}$  acts on  $V_j$  like  $c_j Y^{-1}$ , on  $V'_j$  like  $c'_j Y'^{-1}$ . Set  $c_j = q^p$  and  $c'_j = q^{p'}$ , we get the following:

$$\begin{aligned} P_j e_k &= q^{2k-1+p} e_{k+1} \\ P_j e'_l &= q^{1-2l+p'} e_{l+1} \end{aligned}$$

It follows that the action of  $P_j$  on  $V^j \otimes V'^j$  is given by:

$$P_j \epsilon_{k,l} = q^{2(k-l)+p+p'} \epsilon_{k+1,l+1} \text{ where } \epsilon_{k,l} := e_k \otimes e'_l.$$

In the same way, one sees that the action of  $P_{j+1}$  on  $V^j \otimes V'^j$  is given by:

$$P_{j+1} \epsilon_{k,l} = q^{p+p'} \epsilon_{k-1,l-1}.$$

Now, for  $m, n \in \mathbb{N}$ , set  $\alpha_{m,n} := \sum_{k=0}^{N-1} q^{2km} \epsilon_{k,k+n}$ , an easy calculation shows that:

$$\begin{cases} P_j \alpha_{m,n} = q^{-2(m+n)+p+p'} \alpha_{m,n} \\ P_{j+1} \alpha_{m,n} = q^{2m+p+p'} \alpha_{m,n}. \end{cases}$$

It follows that  $\{\alpha_{n,m}, n, m \in \mathbb{N}\}$  is a base of  $V^j \otimes V'^j$  and, for all  $h_j, h_{j+1} \in \mathcal{U}(N)$ , there exists a unique couple  $(m, n) \in \mathbb{N}_N^2$  with  $h_j = q^{-2(m+n)+p+p'}$  and  $h_{j+1} = q^{2m+p+p'}$ . So  $\dim \mathcal{V}_h^j = 1$  if and only if  $h_k = 1$  for all  $k \notin \{j, j+1\}$ .

iii. If  $k \neq s$ ,  $v_k$  is neither a vertex of  $T_s$  nor  $T'_s$ , so if  $h_k \neq 1$ ,  $\mathcal{V}_{\mathbf{h}}^s = \{0\}$ .

Suppose that  $h_k = 1$  for all  $k \in \{1, \dots, s-1\}$ , then

$$\mathcal{V}_{\mathbf{h}}^s \supset \bigoplus_{h_a h_b = h_s} V_{h_a}^s(P_s) \otimes V_{h_b}^{s'}(P_s),$$

(where  $V_{h_a}^s(P_s)$  and  $\mathcal{V}_{h_b}^s$  are defined as in Lemma 1). The direct sum contains  $N$  terms of dimension one, hence  $\dim \mathcal{V}_{\mathbf{h}}^s \geq N$ . But, we have

$$\dim(V^s \otimes V^{s'}) = N^2 = \sum_{\mathbf{h} \in \mathcal{U}(N)^s} \dim(\mathcal{V}_{\mathbf{h}}^s) \geq N \times N.$$

So  $\mathcal{V}_{\mathbf{h}}^s$  is  $N$ -dimensional. □

Now, the proof of Proposition 2 is straightforward: from Remark 1, we have

$$\bigoplus_{\mathbf{h}^0 \mathbf{h}^1 \dots \mathbf{h}^s = \mathbf{h}} \mathcal{V}_{\mathbf{h}^0}^0 \otimes \dots \otimes \mathcal{V}_{\mathbf{h}^s}^s \otimes \tilde{V} \subset V_{\mathbf{h}}.$$

Writing  $\mathbf{h}^j = (h_1^j, \dots, h_s^j)$  and  $\mathbf{h} = (h_1, \dots, h_s)$ , one notes that the only non-zero terms in the direct sum are those who satisfy:

$$\begin{cases} h_1^0 h_1^1 = h_1 \\ h_2^1 h_2^2 = h_2 \\ \vdots \\ h_s^{s-1} h_s^s = h_s \end{cases}$$

There exists exactly  $N^s$  different choices for  $\mathbf{h}^0, \dots, \mathbf{h}^s \in \mathcal{U}(N)^s$  satisfying the above relations, and each non-zero vector space of the direct sum has dimension  $N^{m-2s}$ . So  $\dim V_{\mathbf{h}} \geq N^{m-s}$ . Now, we have

$$\dim V = N^m = \sum_{\mathbf{h} \in \mathcal{U}(N)^s} \dim V_{\mathbf{h}} \geq N^s \times N^{m-s},$$

and so  $\dim V_{\mathbf{h}} = N^{m-s}$  for each  $\mathbf{h} \in \mathcal{U}(N)$ . □

In particular, it proves the decomposition of Theorem 1 for  $\rho$ . In fact, let  $\rho^{(i)} : \mathcal{T}_q(\lambda_0) \rightarrow \text{End}(V^{(i)})$  be an irreducible representation in the decomposition of  $\rho$ . It must satisfies  $\rho^{(i)}(X_i)^N = \text{Id}_{V^{(i)}}$  and  $\rho^{(i)}(H) = c \text{Id}_{V^{(i)}}$ , in other word,  $\rho^{(i)}$  must be associated to the same weights  $x_i = 1$  and global charge  $c \in \mathcal{U}(N)$  than  $\rho$ .

Set  $h_j^{(i)} \in \mathcal{U}(N)$  the weight of  $\rho^{(i)}$  associated to the each puncture  $v_j$ , that is,  $\rho^{(i)}(P_j) = h_j^{(i)} \text{Id}_{V^{(i)}}$ . Note that, as  $\rho^{(i)}([P_0 \dots P_s]) = \rho^{(i)}([H^2]) = h_0^{(i)} h_1^{(i)} \dots h_s^{(i)} \text{Id}_{V^{(i)}} = c^2 \text{Id}_{V^{(i)}}$ , a necessary condition for  $\rho^{(i)}$  to be in the decomposition of  $\rho$  is to satisfy  $h_0^{(i)} \dots h_s^{(i)} = c^2$ . Hence, if  $\rho^{(i)}$  is in the decomposition of  $\rho$ , knowing  $h_j^{(i)}$  for each  $j = 1, \dots, s$  uniquely determine  $h_0^{(i)}$  and so fully determine  $\rho^{(i)}$ .

Now, as for each  $\mathbf{h} = (h_1, \dots, h_s) \in \mathcal{U}(N)^s$ ,  $V_{\mathbf{h}}$  has dimension  $N^{m-s} = N^{4g-3+(s+1)}$  and as an irreducible representation of  $\mathcal{T}_q(\lambda_0)$  has dimension  $N^{3g-3+(s+1)}$ , then each space  $V_{\mathbf{h}}$  contains exactly  $N^g$  times the representation  $\rho^{(i)}$ , classified by  $p_0 = c^2 h_1^{-1} \dots h_s^{-1}$ ,  $p_1 = h_1, \dots, p_s = h_s$ .

## 2.2 Proof in the global case

Now, to complete the proof of Theorem 1, one remarks that the decomposition of  $\rho$  into irreducible factors only depends on the decomposition of  $\rho(P_j)$  into eigenspaces (for each puncture  $v_j$ ), that is on the possible choices of  $N$ -th root of  $x_1^{k_{j_1}} \dots x_n^{k_{j_n}}$  (where  $P_j$  is associated to the multi-index  $\mathbf{k}_j = (k_{j_1}, \dots, k_{j_n})$ ). But this choice is discrete and depends continuously on the weights  $x_i$  associated to the edge  $\lambda_i$ , hence does not depend on the choice of  $x_i \in \mathbb{C}^*$ . It proves Theorem 1 for the triangulation  $\lambda_0$  and every weight  $x_i \in \mathbb{C}^*$ .

Note that the map  $\varphi_{\lambda_0\lambda}$  defined in Subsection 1.5 is rational, hence defined on a Zariski dense open set of  $\mathbb{C}^n$ . As we extended the decomposition for all weights  $x_i$  associated to each edge of the triangulation  $\lambda_0$ , there exists a local representation  $\{\rho_\lambda : \mathcal{T}_q(\lambda) \rightarrow \text{End}(V_\lambda)\}_{\lambda \in \Lambda(\Sigma)}$  of  $\mathcal{T}_q(\Sigma)$  as defined in Subsection 1.5. So, for each  $\lambda \in \Lambda(\Sigma)$ ,  $\rho_{\lambda_0} \circ \Psi_{\lambda_0\lambda}^q : \mathcal{T}_q(\lambda) \rightarrow \text{End}(V_{\lambda_0})$  makes sense and is isomorphic to  $\rho_\lambda : \mathcal{T}_q(\lambda) \rightarrow \text{End}(V_\lambda)$ . That is, there exists a vector space isomorphism  $L_{\lambda_0\lambda} : V_\lambda \rightarrow V_{\lambda_0}$  such that, for each  $X \in \mathcal{T}_q(\lambda)$ ,

$$\rho_{\lambda_0}(\Psi_{\lambda_0\lambda}^q(X)) = L_{\lambda_0\lambda} \circ \rho_\lambda(X) \circ L_{\lambda_0\lambda}^{-1}.$$

However,  $\rho_{\lambda_0}$  is a local representation of  $\mathcal{T}_q(\lambda_0)$ , hence there exists an irreducible decomposition of  $\rho_{\lambda_0}$  given by the decomposition  $V_{\lambda_0} = \bigoplus_{i \in \mathcal{I}} V_{\lambda_0}^i$  as in

Theorem 1. That is, for each  $i \in \mathcal{I}$ ,  $V_{\lambda_0}^i$  is stable by  $\rho_{\lambda_0}$  and has dimension  $N^{3g-3+s+1}$ .

Using the isomorphism  $\Psi_{\lambda\lambda_0}$ , one gets that for each  $X \in \mathcal{T}_q(\lambda)$ ,  $\rho_{\lambda_0}(\Psi_{\lambda_0\lambda}(X))V_{\lambda_0}^i = V_{\lambda_0}^i$ . Set  $V_\lambda^i := L_{\lambda_0\lambda}^{-1}(V_{\lambda_0}^i)$ , we have  $\dim V_\lambda^i = \dim V_{\lambda_0}^i = 3g - 3 + s + 1$  (because  $L_{\lambda_0\lambda}$  is an isomorphism) so for each  $X \in \mathcal{T}_q(\lambda)$ ,  $\rho_\lambda(X)V_\lambda^i = V_\lambda^i$ . In other words, we have a decomposition

$$\rho_\lambda = \bigoplus_{i \in \mathcal{I}} \rho_\lambda^{(i)},$$

where  $\rho_\lambda^{(i)} : \mathcal{T}_q(\lambda) \rightarrow \text{End}(V_\lambda^i)$ . As each  $V_\lambda^i$  has the dimension of an irreducible representation, we get an irreducible decomposition of  $\rho_\lambda$ . One easily checks that it satisfies the conditions of Theorem 1. Now we extend this decomposition by continuity for all weight  $x_i \in \mathbb{C}^*$  associated to the edge  $\lambda_i$  of  $\lambda$ .
