## Abstract

The effect of substitution on the potential energy surfaces of  $RE_{13}\equiv AsR$  ( $E_{13}$  = group 13 elements;  $R$  = F, OH, H,  $CH_3$ , and  $SiH_3$ ) is determined using density functional theory (M06-2X/Def2-TZVP,B3PW91/Def2-TZVP, and B3LYP/LANL2DZ+dp). The computational studies demonstrate that all triply bonded  $RE_{13}\equiv AsR$  species prefer to adopt a bent geometry that is consistent with the valence electron model. The theoretical studies also demonstrate that  $RE_{13}\equiv AsR$  molecules with smaller substituents are kinetically unstable, with respect to the intramolecular rearrangements. However, triply bonded  $R'E_{13}\equiv AsR'$  species with bulkier substituents ( $R'$  =  $SiMe(Si^tBu_3)_2$ ,  $Si^iPrDis_2$ , and NHC) are found to occupy the lowest minimum on the singlet potential energy surface, and they are both kinetically and thermodynamically stable. That is to say, the electronic and steric effects of bulky substituents play an important role in making molecules that feature an  $E_{13}\equiv As$  triple bond as viable synthetic target.

**Keywords:** arsenic, group 13 elements, triple bond, density functional theory, multiple bond

---

## 1. Introduction

In the past two decades, studies that have been performed by many synthetic chemists have successfully synthesized and characterized homonuclear heavy alkyne-like  $RE_{14}\equiv E_{14}R$  ( $E_{14}$  = Si, Ge, Sn, and Pb) molecules [1–23]. Recently, heteronuclear ethyne-like compounds,  $RC\equiv E_{14}R$ , have also been experimentally studied [24, 25, 26] and theoretically predicted [27, 28, 29].

However, from the valence electron viewpoint,  $RE_{13}\equiv E_{15}R$  ( $E_{13}$  = group 13 elements and  $E_{15}$  = group 15 elements) is isoelectronic with the  $RE_{14}\equiv E_{14}R$  species. Therefore, triply bonded  $RE_{13}\equiv E_{15}R$  is the next synthetic challenge. To the best of the authors' knowledge, only  $R_2BN$  molecules that contain a  $B\equiv N$  triple bond have been experimentally demonstrated to exist [30–40].

## 2. Theoretical methods

This chapter reports the possible existence of triply bonded  $RE_{13}\equiv AsR$  molecules, from the viewpoint of the effect of substituents, using density functional theories (DFT): M06-2X/Def2-TZVP, B3PW91/Def2-TZVP, and B3LYP/LANL2DZ+dp for small substituents and B3LYP/LANL2DZ+dp//RHF/3-21G\* for large substituents. It is hoped that this theoretical study will stimulate further research into the synthetic chemistry of triply bonded  $RE_{13}\equiv AsR$  species.

## 3. Results and discussion

### 3.1. Small ligands on substituted $RE_{13}\equiv AsR$

The effect of the electronegativity of six types of small substituents ( $R = F, OH, H, CH_3,$  and  $SiH_3$ ) on the stability of the triply bonded  $RE_{13}\equiv AsR$  molecules is determined using the three DFT methods. The molecular properties (geometrical parameters, singlet-triplet energy splitting, natural charge densities, binding energies (BE), and the Wiberg Bond Index (WBI)) are all listed in **Tables 1–5**. The reaction profiles for the unimolecular rearrangement reactions for the  $RE_{13}\equiv AsR$  compounds are also given in **Figures 1–5**.

There are three noteworthy features of **Tables 1–5** and **Figures 1–5**.

1. From the tables, the three DFT calculations show that the triple bond distances ( $\text{\AA}$ ) for  $B\equiv As$ ,  $Al\equiv As$ ,  $Ga\equiv As$ ,  $In\equiv As$ , and  $Tl\equiv As$  are estimated to be 1.835–1.908 (**Table 1**), 2.218–2.358 (**Table 2**), 2.239–2.364 (**Table 3**), 2.404–2.546 (**Table 4**), and 2.426–2.570 (**Table 5**). As previously mentioned, no experimental values for these triple bond lengths have been reported, so these computational data are a prediction.
2. In **Tables 1–5**, these DFT computations all demonstrate that the triply bonded  $RE_{13}\equiv AsR$  molecules favor a bent structure, rather than a linear structure. This is explained by the bonding model, as shown in **Figure 6**. Because there is a significant difference between the sizes of the valence  $s$  and  $p$  atomic orbitals in the  $As$  atom, hybrid orbitals between the valence  $s$  and  $p$  orbitals are not easily formed (the so-called orbital non-hybridization effect or the inert  $s$ -pair effect) [41–44]. Therefore,  $RE_{13}\equiv AsR$  molecules that have a heavier  $As$  center are predicted to favor a bent angle  $\angle E_{13}-As-R$  (close to  $90^\circ$ ). The DFT computational data that are shown in **Tables 1–5** confirm this prediction.

2 The natural charge density on the As atom.

3 BE = E(triplet state for R-Al) + E(triplet state for R-As) - E(singlet state for RAl≡AsR).

4 The Wiberg bond index (WBI) for the Al-As bond: see [45, 46].

**Table 2.** The main geometrical parameters, the singlet-triplet energy splitting ( $\Delta E_{ST}$ ), the natural charge densities ( $Q_{Al}$  and  $Q_{As}$ ), the binding energies (BE), and the Wiberg Bond Index (WBI) for RAl≡AsR using the M06-2X/Def2-TZVP, B3PW91/Def2-TZVP (in round brackets), and B3LYP/LANL2DZ+dp (in square brackets) levels of theory.

3. In terms of the stability of the  $RE_{13}\equiv AsR$  species, the three DFT computations are used to study the energy surfaces for the  $RE_{13}\equiv AsR$  systems, and the theoretical results are shown in **Figures 1–5**. These figures show three local minima (i.e.,  $R_2E_{13}=As$ ,  $RE_{13}\equiv AsR$ , and  $E_{13}=AsR_2$ ) and two saddle points that connect them. It is seen that regardless of the type of small substituent, triply bonded  $RE_{13}\equiv AsR$  molecules are unstable on the potential energy surfaces, so they easily undergo a 1,2-migration reaction to produce the most stable doubly bonded isomers. There is strong theoretical evidence that there is no possibility of observing triply bonded  $RE_{13}\equiv AsR$  compounds in transient intermediates or even in a matrix.

### 3.2. Large ligands on substituted $R'E_{13}\equiv AsR'$

Bulky substituents are used to determine the possible existence of triply bonded  $R'E_{13}\equiv AsR'$  ( $R' = SiMe(Si^tBu_3)_2$ ,  $Si^iPrDis_2$ , and NHC; (**Scheme 1**)) molecules. The molecular properties, the natural bond orbital (NBO) [45, 46], and the natural resonance theory (NRT) [47, 48, 49] analyses of  $R'E_{13}\equiv AsR'$  are computed at the B3LYP/LANL2DZ+dp//RHF/3-21G\* level of theory, and the results are shown in **Tables 6, 7** ( $R'B\equiv AsR'$ ), **8, 9** ( $R'Al\equiv AsR'$ ), **10, 11** ( $R'Ga\equiv AsR'$ ), **12, 13** ( $R'In\equiv AsR'$ ), and **14 and 15** ( $R'Tl\equiv AsR'$ ).

The results in **Tables 6–15** allow three conclusions to be drawn.

1. The calculations that are shown in **Tables 6 (B)**, **8 (Al)**, **10 (Ga)**, **12 (In)**, and **14 (Tl)** show that the computed  $E_{13}\equiv\text{As}$  triple bond distances ( $\text{\AA}$ ) for these bulkily substituted species ( $R'E_{13}\equiv\text{As}R'$ ) are estimated to be 1.821–1.837 ( $\text{B}\equiv\text{As}$ ), 2.257–2.307 ( $\text{Al}\equiv\text{As}$ ), 2.252–2.316 ( $\text{Ga}\equiv\text{As}$ ), 2.430–2.482 ( $\text{In}\equiv\text{As}$ ), and 2.565–2.653 ( $\text{Tl}\equiv\text{As}$ ). The values for the WBO that are shown in **Tables 6–10** (for bulky ligands) are obviously greater than those that are shown in **Tables 1–5** (for smaller ligands). These WBO values show that bulkier substituents increase the bond order for the  $E_{13}\equiv\text{As}$  triple bond length.
2. Similarly to the results for small ligands, the computational results show that  $R'E_{13}\equiv\text{As}R'$  species that feature large substituents all adopt a bent conformation. This phenomenon is explained by bonding model (II), which is shown in **Figure 6**.
3. The NBO values that are shown in **Tables 7 (B $\equiv\text{As}$ )**, **9 (Al $\equiv\text{As}$ )**, **11 (Ga $\equiv\text{As}$ )**, **13 (In $\equiv\text{As}$ )**, and **15 (Tl $\equiv\text{As}$ )** show that the acetylene-like  $R'E_{13}\equiv\text{As}R'$  compounds feature a weak triple bond. For example, the B3LYP/LANL2DZ+dp data for the NBO analyses of the  $\text{B}\equiv\text{As}$   $\pi$  bonding in  $(\text{Si}i\text{PrDis}_2-\text{B}\equiv\text{As}-\text{Si}i\text{PrDis}_2)$ , which shows that  $\text{NBO}(\text{B}\equiv\text{As}) = 0.5880(2s2p^{99.99})\text{B} + 0.8089(4s4p^{1.00})\text{As}$ , provide strong evidence that the predominant bonding interaction between the  $\text{B}-\text{Si}i\text{PrDis}_2$  and the  $\text{As}-\text{Si}i\text{PrDis}_2$  units results from  $2p(\text{B}) \leftarrow 4p(\text{As})$  donation, whereby boron's electron deficiency and  $\pi$  bond polarity are partially balanced by the donation of the arsenic lone pair into the empty boron  $p$  orbital to develop a hybrid  $\pi$  bond. The polarization analyses using the NBO model again demonstrate the presence of the  $\text{B}\equiv\text{As}$   $\pi$  bonding orbital, 34.58% of which is composed of natural B orbitals and 65.42% of which is natural As orbitals. **Table 7** also shows that the  $\text{B}\equiv\text{As}$  triple bond in  $(\text{Si}i\text{PrDis}_2-\text{B}\equiv\text{As}-\text{Si}i\text{PrDis}_2)$  has a shorter single bond character (6.04%) and a shorter triple bond character (36.74%), but a greater double bond character (57.2%), because the ionic part of the NRT bond order (0.53) is shorter than its covalent part (1.71). The same theoretical observations are also seen for the other two differently substituted  $R'B\equiv\text{As}R'$  compounds, as shown in **Table 7**, and in the data for the other  $R'E_{13}\equiv\text{Bi}R'$  compounds that is shown in **Tables 9 (Al)**, **11 (Ga)**, **13 (In)**, and **15 (Tl)**. These computational data demonstrate that these  $R'E_{13}\equiv\text{As}R'$  molecules have a weak  $E_{13}\equiv\text{As}$  triple bond.

**Scheme 1.** Three bulky ligands:  $\text{SiMe}(\text{Si}^t\text{Bu}_3)_2$ ,  $\text{Si}^i\text{PrDis}_2$ , and N-heterocyclic carbene.

## 4. Conclusion

This study of the effect of substituents on the possibility of the existence of triply bonded RE<sub>13</sub>≡AsR allows the following conclusions to be drawn (**Scheme 2**):

1. The theoretical observations provide strong evidence that bonding mode (B) is dominant in the triply bonded RE<sub>13</sub>≡BiR species, because their structures are bent due to electron transfer (denoted by arrows in **Figure 1**) and the relativistic effect, which increases stability.
2. The theoretical evidence shows that both the electronic and the steric effects of substituents are crucial to rendering the E<sub>13</sub>≡As triple bond synthetically accessible. However, this theoretical study shows that these E<sub>13</sub>≡As triple bonds are weak. They are not as strong as the traditional C≡C triple bond. The results of this theoretical study show that triply bonded R'E<sub>13</sub>≡AsR' molecules that feature bulky substituents are more stable because bulky substituents not only protect the central E<sub>13</sub>≡As triple bond because there is large steric hindrance but also prohibit polymerization reactions.

$E_{13} = \text{B, Al, Ga, In, and Tl}$

$R = \left\{ \begin{array}{l} \text{F, HO, H, CH}_3, \text{ and SiH}_3 \\ \text{SiMe(Si}t\text{Bu}_3)_2, \text{ Si}i\text{PrDis}_2, \text{ and NHC} \end{array} \right.$

**Scheme 2.** The predicted structure for the triply bonded  $\text{RE}_{13}\equiv\text{AsR}$  molecules based on the present theoretical computations.
