A B S T R A C T

Background

Liver transplantation is an established treatment option for end-stage liver failure. Now that newer, more potent immunosuppressants have been developed, glucocorticosteroids may no longer be needed and their removal may prevent adverse effects.

Objectives

To assess the benefits and harms of glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) or withdrawal versus glucocorticosteroid-containing immunosuppression following liver transplantation.

Search methods

We searched the Cochrane Hepato-Biliary Group Controlled Trials Register, Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, Science Citation Index Expanded and Conference Proceedings Citation Index - Science, Literatura Americano e do Caribe em Ciencias da Saude (LILACS), World Health Organization International Clinical Trials Registry Platform, ClinicalTrials.gov, and The Transplant Library until May 2017.

Selection criteria

Randomised clinical trials assessing glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression for liver transplanted people. Our inclusion criteria stated that participants should have received the same co-interventions. We included trials that assessed complete glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) versus short-term glucocorticosteroids, as well as trials that assessed short-term glucocorticosteroids versus long-term glucocorticosteroids.

Data collection and analysis

We used RevMan to conduct meta-analyses, calculating risk ratio (RR) for dichotomous variables and mean difference (MD) for continuous variables, both with 95% confidence intervals (CIs). We used a random-effects model and a fixed-effect model and reported both results where a discrepancy existed; otherwise we reported only the results from the fixed-effect model. We assessed the risk of systematic errors using 'Risk of bias' domains. We controlled for random errors by performing Trial Sequential Analysis. We presented our results in a 'Summary of findings' table.

Main results

We included 17 completed randomised clinical trials, but only 16 studies with 1347 participants provided data for the meta-analyses. Ten of the 16 trials assessed complete postoperative glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) versus short-term glucocorticosteroids (782 participants) and six trials assessed short-term glucocorticosteroids versus long-term glucocorticosteroids (565 participants). One additional study assessed complete post-operative glucocorticosteroid avoidance but could only be incorporated into qualitative analysis of the results due to limited data published in an abstract. All trials were at high risk of bias. Only eight trials reported on the type of donor used. Overall, we found no statistically significant difference for mortality (RR 1.15, 95% CI 0.93 to 1.44; low-quality evidence), graft loss including death (RR 1.15, 95% CI 0.90 to 1.46; low-quality evidence), or infection (RR 0.88, 95% CI 0.73 to 1.05; very low-quality evidence) when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression. Acute rejection and glucocorticosteroid-resistant rejection were statistically significantly more frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (RR 1.33, 95% CI 1.08 to 1.64; low-quality evidence; and RR 2.14, 95% CI 1.13 to 4.02; very low-quality evidence). Diabetes mellitus and hypertension were statistically significantly less frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (RR 0.81, 95% CI 0.66 to 0.99; low-quality evidence; and RR 0.76, 95% CI 0.65 to 0.90; low-quality evidence). We performed Trial Sequential Analysis for all outcomes. None of the outcomes crossed the monitoring boundaries or reached the required information size. Hence, we cannot exclude random errors from the results of the conventional meta-analyses.

Authors' conclusions

Many of the benefits and harms of glucocorticosteroid avoidance or withdrawal remain uncertain because of the limited number of published randomised clinical trials, limited numbers of participants and outcomes, and high risk of bias in the trials. Glucocorticosteroid avoidance or withdrawal appears to reduce diabetes mellitus and hypertension whilst increasing acute rejection, glucocorticosteroid-resistant rejection, and renal impairment. We could identify no other benefits or harms of glucocorticosteroid avoidance or withdrawal. Glucocorticosteroid avoidance or withdrawal may be of benefit in selected patients, especially those at low risk of rejection and high risk of hypertension or diabetes mellitus. The optimal duration of glucocorticosteroid administration remains unclear. More randomised clinical trials assessing glucocorticosteroid avoidance or withdrawal are needed. These should be large, high-quality trials that minimise the risk of random and systematic error.

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients

Review question

We assessed whether avoiding or withdrawing glucocorticosteroids was better or worse than continuing to use glucocorticosteroids for immunosuppression after liver transplantation.

Background

Glucocorticosteroids are used to prevent rejection of the liver after transplantation by suppressing the immune system. Some centres use glucocorticosteroids indefinitely after liver transplantation whilst others slowly reduce them, and others do not use glucocorticosteroids at all. Glucocorticosteroids have a number of important adverse effects, which may lead to illness and sometimes death in liver transplantation. These adverse effects include diabetes mellitus, high blood pressure, and infection.

With recent developments in immunosuppression, glucocorticosteroids no longer feature as the main immunosuppressant used following transplantation. The use of new immunosuppressant medication may mean that glucocorticosteroids may no longer be necessary after transplantation. Rather than helping to prevent rejection of the liver graft they might cause adverse effects. The benefits of avoiding glucocorticosteroids or withdrawing them after a short while remain unclear.

Study characteristics

We searched for trials comparing glucocorticosteroid avoidance or withdrawal to continuing glucocorticosteroids. Seventeen randomised clinical trials were included, of which 16 trials involving 1347 participants provided numeric data for the meta-analyses. All of the studies assessed adults who had received a liver transplant. Of the 16 randomised clinical trials included in the meta-analyses, 10 trials assessed avoidance of glucocorticosteroids compared with slowly reducing glucocorticosteroids (782 participants) and six trials assessed

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients (Review)   2

withdrawal of glucocorticosteroids following a slow reduction compared with a longer reduction or long-term use of glucocorticosteroids (565 participants). Only eight trials reported on the type of donor used. The evidence is current to May 2017.

Key results

Rejection, severe rejection, and kidney failure may be increased by avoiding or withdrawing glucocorticosteroids compared with continuing glucocorticosteroids. Diabetes mellitus and high blood pressure may be reduced by avoiding or withdrawing glucocorticosteroids compared with continuing glucocorticosteroids. We did not find any difference in survival of the patients, survival of the liver, other adverse effects, or health-related quality of life.

Quality of the evidence

We assessed all of the trials we included as being at high risk of bias, which means that they may overestimate the benefits and underestimate the harms of avoiding or withdrawing glucocorticosteroids. The evidence was either low quality or very low quality.

Conclusion

There is still some uncertainty about the benefits and harms of avoiding or withdrawing glucocorticosteroids after transplantation. Avoiding or withdrawing glucocorticosteroids appears to increase rejection, severe rejection, and kidney failure but seems to reduce diabetes mellitus and high blood pressure. We found no other obvious benefits or harms of avoiding or withdrawing glucocorticosteroids. More randomised clinical trials are needed to assess avoidance and withdrawal of glucocorticosteroids for liver transplanted patients.

SUMMARY OF FINDINGS FOR THE MAIN COMPARISON [*Explanation*]

Glucocorticosteroid avoidance or withdrawal compared to glucocorticosteroid-based immunosuppression for liver transplanted patients

Patient or population: liver transplanted patients
Setting: inpatient and outpatient
Intervention: glucocorticosteroid avoidance or withdrawal
Comparison: glucocorticosteroid-based immunosuppression

Outcomes**	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	№ of participants (trials)	Quality of the evidence (GRADE)	Comments
	Risk with glucocorticosteroid-based immunosuppression	Risk with glucocorticosteroid avoidance or withdrawal				
All-cause mortality	Study population		RR 1.15 (0.93 to 1.44)	1323 (15 RCTs)	⊕⊕◯◯ LOW [1,2]	The quality of the evidence was considered low for both glucocorticosteroid avoidance and glucocorticosteroid withdrawal. Trial Sequential Analysis-adjusted CI 0.77-1.66
	166 per 1000	191 per 1000 (154 to 239)				
	Moderate					
	204 per 1000	234 per 1000 (189 to 293)				
Graft loss including death	Study population		RR 1.15 (0.90 to 1.46)	1002 (11 RCTs)	⊕⊕◯◯ LOW [1,2]	The quality of the evidence was considered low for both glucocorticosteroid avoidance and glucocorticosteroid withdrawal. Trial Sequential Analysis-adjusted CI 0.75-2.01
	175 per 1000	203 per 1000 (159 to 259)				
	Moderate					
	218 per 1000	253 per 1000 (198 to 322)				

Acute rejection	Study population		RR 1.33 (1.08 to 1.64)	1347 (16 RCTs)	⊕⊕○○ LOW [1,2]	The quality of the evidence was considered low both glucocorticosteroid avoidance and glucocorticosteroid withdrawal. Trial Sequential Analysis-adjusted CI 0.92-1.90

*__The risk in the intervention group__ (and its 95% confidence interval) is based on the assumed risk in the comparison group and the __relative effect__ of the intervention (and its 95% CI).

**We assessed all outcomes at latest follow-up (range 13 months to 108 months)

CI: confidence interval; **RR:** risk ratio; **RCT:** randomised clinical trial

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

[1] Downgraded one level due to risk of bias: all trials were at high risk of bias.

[2] Downgraded one level due to imprecision identified in the Trial Sequential Analysis; 95% CI includes both benefit and harm.

[3] Downgraded one level due to significant heterogeneity identified between subgroups; avoidance versus withdrawal.

BACKGROUND

Liver transplantation is an established treatment option for end-stage liver failure in selected patients and results in improved quality and quantity of life (Pillai 2009; Dienstag 2012). Currently, liver transplant recipients have a one-year survival of over 90% and a five-year survival of over 75% (Perera 2009).

Description of the condition

Over 1800 liver transplantations per year (whole liver or split liver) were performed from post-mortem and living donors in the Eurotransplant region from 2008 to 2012 (Eurotransplant 2012). However, at the end of 2011 there were 2406 people in need of liver transplantation (Eurotransplant 2012). In the UK, 784 liver transplantations were carried out in 2012 through 2013, but 494 patients remained on the waiting list as of 31 March 2013 (NHS Blood and Transplant 2013). In the USA, 6445 livers were transplanted in 2013 including 252 living donor liver transplants (OPTN 2014). In 2012, in the UK, the indications for liver transplantation from deceased donors included alcoholic liver disease (18.5%), hepatitis C virus (HCV) cirrhosis (8.1%), hepatocellular carcinoma (17.1%), primary sclerosing cholangitis (8.2%), primary biliary cirrhosis (7.6%), and metabolic diseases (8.1%). Of the deceased donor transplants, 88% were elective procedures and 12% for fulminant hepatic failure (Johnson 2014).

Description of the intervention

Liver transplant recipients have to take life-long immunosuppressive medication in order to achieve an effective prophylaxis against allograft rejection. The most commonly used immunosuppressive agents are calcineurin inhibitors (e.g. cyclosporine, tacrolimus), antiproliferative agents (e.g. azathioprine, mycophenolate mofetil), and glucocorticosteroids (e.g. methylprednisolone). In addition, mammalian target of rapamycin inhibitors (e.g. sirolimus, everolimus) are used to prevent rejection. Induction agents are often used to prevent rejection and facilitate calcineurin inhibitor and glucocorticosteroid minimisation (Lupo 2008; Neumann 2012; Kim 2013; Herzer 2016). Glucocorticosteroids decrease interleukin 1, 2, and 6 activity and non-specifically inhibit T-cell activation. Adverse effects due to glucocorticosteroids such as hypertension, hyperglycaemia, hypercholesterolaemia, and obesity are well known. In some cases, hypertension is reported in over 50% of patients (Neal 2005; Llado 2006), but a glucocorticosteroid bolus is still given at the time of transplantation and tapered after a while (Fernandez 1998; Hatz 1998; Renoult 2005; Hirose 2006). Cyclosporin A and tacrolimus are both calcineurin inhibitors. Calcineurin normally activates nuclear factor of activated T cells, which leads to production of interleukin 2 and 4 that stimulate growth and differentiation of the T-cell response. Tacrolimus is used more widely than cyclosporin

due to reduced acute rejection and increased graft survival, but tacrolimus carries a higher risk of new-onset diabetes after transplant (NODAT) (Ho 1996; Ojo 2003; Haddad 2006). Despite the favourable profile of tacrolimus compared with cyclosporine, tacrolimus still carries a significant risk of renal failure and many trials have investigated the replacement of tacrolimus with other drugs, usually sirolimus or everolimus (Penninga 2012; Sterneck 2014). Mycophenolate mofetil (MMF; also known as mycophenolic acid; MPA) inhibits inosine monophosphate dehydrogenase (IMPDH). This enzyme is responsible for de novo synthesis of guanosine nucleotides. The inhibition by MMF has cytostatic effects on T- and B-lymphocytes. MMF is still preferred to azathioprine (Allison 2000; Knight 2009).

How the intervention might work

Through the use of calcineurin inhibitors, liver transplantation has become a standard procedure with good long-term results (Haddad 2006). However, the burden of life-long immunosuppressive treatment in liver transplant recipients causes increased morbidity and mortality. Optimal long-term immunosuppressive treatment to reduce morbidity and mortality without leading to graft loss has become of major importance. Treatment with glucocorticosteroids induces bone loss and may lead to cardiovascular risk factors (e.g. hypertension, hyperlipidaemia, obesity, glucose intolerance) (Hatz 1998). Avoidance of glucocorticosteroids may reduce this excess morbidity without having an effect on graft loss (Knight 2011). In addition, use of glucocorticosteroids after transplantation might reduce physical and mental health-related quality of life, and increase symptoms of anxiety (Zaydfudim 2012). Furthermore, glucocorticosteroids might increase the risk and severity of hepatitis C recurrence in patients transplanted for hepatitis C. Hence, glucocorticosteroid avoidance and reduction regimens for liver transplant recipients have been developed and studied, but it is still uncertain whether these regimens offer clear benefits (Segev 2008). These long-term adverse events and the development of relatively new immunosuppressive medication (e.g. basiliximab) may potentially enable the reduction or withdrawal of glucocorticosteroids as an immunosuppressive treatment (Vanrenterghem 1999; Ganschow 2005; Penninga 2014).

There is some evidence that glucocorticosteroid avoidance or withdrawal could be beneficial (Adams 2001; Kato 2005; Cintorino 2006; Llado 2006; Moench 2007; Penninga 2014a), but the overall effect still remains unclear. Five reviews with meta-analyses on glucocorticosteroid avoidance or withdrawal for liver transplanted people have been published, showing a possible advantage in cardiovascular risk factors (e.g. diabetes mellitus, hypertension), a possible benefit in cytomegalovirus (CMV) infection and a possible benefit for people transplanted for HCV-induced liver disease (Segev 2008; Sgourakis 2009; Knight 2011; Gu 2014; Lan 2014). One Cochrane network meta-analysis of maintenance immunosuppression for liver transplanted patients has been pub-

lished showing a possible decrease in adverse events, but a possible increase in retransplantation with glucocorticosteroid avoidance or withdrawal (Rodríguez-Perálvarez 2017).

Why it is important to do this review

It is possible that glucocorticosteroids could be withdrawn following liver transplantation or completely avoided without any negative effects whilst reducing the adverse effects associated with glucocorticosteroids. However, people may face more adverse events due to increased use of other immunosuppressants.

O B J E C T I V E S

To assess the benefits and harms of glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) or withdrawal versus glucocorticosteroid-containing immunosuppression following liver transplantation.

M E T H O D S

Criteria for considering studies for this review

Types of studies

We included randomised clinical trials evaluating the benefits and harms of complete glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) or withdrawal versus glucocorticosteroid-containing immunosuppression for liver transplanted people. We did not include non-randomised clinical trials or trials that reported per-treatment analysis rather than intention-to-treat analysis. For evaluation of harms, we included quasi-randomised clinical trials and observational trials that we identified during our searches for randomised clinical trials.
We did not apply any restrictions on date of publication, language, or publication status (published or unpublished work).

Types of participants

We included people of any age, sex, and ethnic group during and after liver transplantation, in any care setting, irrespective of diagnosis and disease stage, type of graft (live donor, cadaveric, split, whole, domino), and prescribed medication. We did not include participants with other transplanted organs or those with a previous liver transplant.

Types of interventions

We included randomised clinical trials that investigated weaning off, versus not weaning off, glucocorticosteroids, as well as trials that compared standard immunosuppression without glucocorticosteroids versus standard immunosuppression including glucocorticosteroids directly following transplantation.
We allowed co-interventions (e.g. induction with basiliximab, co-administration of an antiproliferative such as mycophenolate mofetil) if received equally by all intervention groups of the trial.

Types of outcome measures

Outcome measures did not form part of the eligibility criteria for including trials in this review. We assessed all outcomes at latest follow-up.

Primary outcomes

- All-cause mortality.
- Graft loss including death.
- Acute rejection. This is diagnosed by the combination of abnormal liver biochemical variables (e.g. bilirubin, aspartate transaminase, alanine transaminase, alkaline phosphatases, gamma glutamyl transpeptidase), clinical signs such as fever, and liver histological changes including mononuclear portal inflammation, bile duct damage, and subendothelial inflammation of portal or terminal hepatic veins (IWP 1995; IP 2000).
- Infection.

We have not included serious adverse events as an outcome as following organ transplantation the number of serious adverse events is extremely high. As a result of this, very few trials in transplantation report serious adverse events as an outcome and instead report outcomes individually (e.g. diabetes mellitus, infection, hypertension). As well as this, most transplant recipients experience one or more serious adverse events following transplantation, meaning that the number of adverse events may be 100% in both groups. This means neither complete nor consistent serious adverse event reporting can be guaranteed. Instead, we analysed selected outcomes individually.

Secondary outcomes

- Other adverse events. Adverse events were defined as any untoward medical occurrence not necessarily having a causal relationship with the treatment but resulting in a dose reduction or discontinuation of treatment (ICH-GCP 1997).
- Chronic rejection. Chronic rejection was characterised by liver histological changes including the progressive loss of interlobular bile ducts and arteriopathy characterised by foam cell infiltration of the arterial intima.
- Glucocorticosteroid-resistant rejection.

- Diabetes mellitus (de novo diabetes mellitus as described in the study or total number of people with diabetes mellitus).
- Cytomegalovirus (CMV) infection (infection requiring treatment).
- Hepatitis C virus (HCV) recurrence.
- Malignancy.
- Post-transplantation lymphoproliferative disorder (PTLD).
- Renal function (renal failure requiring dialysis, renal insufficiency, estimated glomerular filtration rate, and serum creatinine).
- De novo autoimmune hepatitis.
- Hypertension.
- Hyperlipidaemia.
- Cholesterol (serum cholesterol and hypercholesterolaemia).
- Health-related quality of life.

Search methods for identification of studies

We searched for eligible trials for the earliest entrance date possible until the latest search date.
We managed all references with Refworks©.

Electronic searches

We searched the Cochrane Hepato-Biliary Group Controlled Trials Register (Gluud 2018; May 2017), Cochrane Central Register of Controlled Trials (CENTRAL; 2017, Issue 5), MEDLINE Ovid (1946 to May 2017), Embase Ovid (1974 to May 2017), Science Citation Index Expanded (Web of Science; 1900 to May 2017), Conference Proceedings Citation Index - Science (Web of Science; 1990 to May 2017) (Royle 2003) and LILACS (Literatura Americano e do Caribe em Ciencias da Saude; Clark 2002; 1982 to May 2017). Appendix 1 gives the search strategies with the time spans of the searches. As the review progressed, we did not need to improve the search strategies.
We also searched the World Health Organization International Clinical Trials Registry Platform (apps.who.int/ trialsearch/), ClinicalTrials.gov (clinicaltrials.gov/), and The Transplant Library (Pengel 2011).

Searching other resources

We contacted experts in the field, such as scientific societies for liver transplantation, and we asked whether they have been involved in any further trials or are aware of recent or ongoing trials on the effects of glucocorticosteroids for liver transplanted patients. We tried to identify unpublished trials by contacting manufacturers of glucocorticosteroids (i.e. Ratiopharm, Astellas, Aventis, Novartis, Merck, Hexal, Pfizer, Roche).
We searched the reference lists of identified trials, non-randomised trials, and other systematic reviews for additional publications of interest.

Data collection and analysis

Selection of studies

Four review authors (CF, EH, JP, SW) independently assessed the retrieved references for eligibility and resolved disagreements by discussion with another author (LP). The excluded studies and the reasons for their exclusion are listed in the table Characteristics of excluded studies.

Data extraction and management

We extracted data on source, inclusion and exclusion criteria, description of participants and setting, interventions and co-interventions, outcomes, and sample size calculation using a data extraction sheet. We did not identify any cross-over trials. We extracted data using the intention-to-treat principle. We translated all trials reported in non-English language journals before assessment. Where multiple publications of a trial exist, we grouped the publications together and we extracted data from the most complete publication and any relevant outcomes that are only reported in one of the other publications. Where further information was required, we contacted the original authors requesting this.

Assessment of risk of bias in included studies

Four review authors (CF, JP, EH, SW) independently assessed the risk of bias of the trials, without masking them. We followed the instructions given in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011), and the Cochrane Hepato-Biliary Group Module (Gluud 2018). Due to the risk of biased overestimation of beneficial intervention effects (or underestimating of harmful effects) in randomised trials (Schulz 1995; Moher 1998; Kjaergard 2001; Wood 2008; Savović 2012; Savović 2012a; Lundh 2017), we assessed the following bias risk domains with definitions below. If information was not available in the published trial, we contacted the authors in order to assess the trials correctly.

Allocation sequence generation

- Low risk of bias: sequence generation was achieved using computer random number generation or a random number table. Drawing lots, tossing a coin, shuffling cards, and throwing dice are adequate if performed by an independent person not otherwise involved in the trial.
- Uncertain risk of bias: the method of sequence generation was not specified.
- High risk of bias: the sequence generation method was not random.

Allocation concealment

- Low risk of bias: the participant allocations could not have been foreseen in advance of, or during, enrolment. Allocation was controlled by a central and independent randomisation unit. The allocation sequence was unknown to the investigators (e.g. if the allocation sequence was hidden in sequentially numbered, opaque, and sealed envelopes).
- Uncertain risk of bias: the method used to conceal the allocation was not described so that intervention allocations may have been foreseen in advance of, or during, enrolment.
- High risk of bias: the allocation sequence was likely to be known to the investigators who assigned the participants.

Blinding of participants and personnel

- Low risk of bias: it was mentioned that both participants and personnel providing the interventions were blinded, and the method of blinding was described, so that knowledge of allocation was prevented during the trial.
- Unclear risk of bias: it was not mentioned if the trial was blinded, or the trial was described as blinded, but the method or extent of blinding was not described, so that knowledge of allocation was possible during the trial.
- High risk of bias: the trial was not blinded, so that the allocation was known during the trial.

Blinded outcome assessment

- Low risk of bias: it was mentioned that both participants and personnel providing the interventions were blinded, and the method of blinding was described, so that knowledge of allocation was prevented during the trial.
- Unclear risk of bias: it was not mentioned if the trial was blinded, or the trial was described as blinded, but the method or extent of blinding was not described, so that knowledge of allocation was possible during the trial.
- High risk of bias: the trial was not blinded, so that the allocation was known during the trial.

Incomplete outcome data

- Low risk of bias: missing data were unlikely to make treatment effects depart from plausible values. Sufficient methods, such as multiple imputation, have been employed to handle missing data.
- Uncertain risk of bias: there was insufficient information to assess whether missing data in combination with the method used to handle missing data were likely to induce bias in the results.
- High risk of bias: the results were likely to be biased due to missing data.

Selective outcome reporting

- Low risk: the trial reported the following pre-defined outcomes: all-cause mortality, graft loss including death, acute rejection, and infection. If the original trial protocol was available, the outcomes should be those called for in that protocol. If the trial protocol was obtained from a trial registry (e.g. www.clinicaltrials.gov), the outcomes sought should have been those enumerated in the original protocol if the trial protocol was registered before or at the time that the trial was begun. If the trial protocol was registered after the trial was begun, we did not consider those outcomes to be reliable.
- Unclear risk: not all pre-defined outcomes were reported fully, or it was unclear whether data on these outcomes were recorded or not.
- High risk: one or more pre-defined outcomes were not reported.

For-profit bias

- Low risk of bias: the trial appears to be free of industry sponsorship or other type of for-profit support that may manipulate the trial design, conduct, or results of the trial.
- Uncertain risk of bias: the trial may or may not be free of for-profit bias as no information on clinical trial support or sponsorship was provided.
- High risk of bias: the trial was sponsored by industry or received another type of for-profit support.

Other risk of bias

- Low risk of bias: the trial appears to be free of other components that could put it at risk of bias.
- Uncertain risk of bias: the trial may or may not be free of other components that could put it at risk of bias.
- High risk of bias: there are other factors in the trial that could put it at risk of bias.

We considered trials assessed as having 'low risk of bias' in all of the specified individual domains as trials with 'low risk of bias'. We considered trials assessed as having 'uncertain risk of bias' or 'high risk of bias' in one or more of the specified individual domains as trials with 'high risk of bias'.

Measures of treatment effect

For dichotomous variables, we used risk ratio (RR) and 95% confidence intervals (CI).

For continuous variables, we used the mean difference (MD) with 95% CI. If we had been able to identify different measures for the health-related quality of life outcome, we would have used standardised mean difference (SMD) with 95% CIs.

Unit of analysis issues

In the case of trials using multiple treatment groups, we considered only the group in which glucocorticosteroids were administered versus the group in which either placebo or no intervention was administered. If we had been able to identify trials assessing two or more groups with different glucocorticosteroid-containing immunosuppression regimens compared to a control group, we would have included data from all the groups and ensured that participants were included only once per meta-analysis. If we had been able to identify any cross-over trials, we would have extracted data from the first period of treatment only.

Dealing with missing data

Where possible, we contacted the original authors of articles with missing outcomes, missing summary data, or missing individual data to request the missing data.

We included all participants irrespective of compliance or follow-up. We analysed all available data and performed best-worst and worst-best case scenario analyses in the event of missing data.

Assessment of heterogeneity

We explored heterogeneity by the Chi^2 test with significance set at P = 0.01, and we measured the quantity of heterogeneity with the I^2 statistic (Higgins 2002).

We assessed clinical heterogeneity by examining the included trials for differences between the trials in types of participants (including age, indication for transplantation, and presence of hepatitis C infection), quantity of glucocorticosteroid used (duration of treatment and daily dose), and additional immunosuppression (use of induction agents, use of antiproliferative agents, and use of calcineurin inhibitors).

Assessment of reporting biases

We used a funnel plot to explore publication bias (Egger 1997; Macaskill 2001), as we identified more than 10 randomised trials. We used the linear regression approach described by Egger and colleagues to determine the funnel plot asymmetry (Egger 1997).

Data synthesis

We performed the meta-analyses according to the recommendations of Cochrane (Higgins 2011), and the Cochrane Hepato-Biliary Group Module (Gluud 2018). We used the software package Review Manager 5.3 to conduct meta-analyses when there were two or more eligible trials (RevMan 2014). For dichotomous variables, we calculated the risk ratio (RR) with 95% confidence interval. For continuous variables, we calculated the mean difference (MD) with 95% confidence interval. We used a random-effects model (DerSimonian 1986), and a fixed-effect model (DeMets 1987). In case of discrepancy between the two models, we reported

both results; otherwise, we reported only the results from the fixed-effect model. We grouped trials investigating complete avoidance of glucocorticosteroids together with trials investigating a rapid taper of glucocorticosteroids as 'glucocorticosteroid avoidance and withdrawal' (Gluc avoid) protocols. We presented both avoidance and rapid tapers as separate subtotals and where a discrepancy exists between the two protocols, we reported both results separately.

Trial Sequential Analysis

We applied Trial Sequential Analysis, as cumulative meta-analyses are at risk of producing random errors because of sparse data and repetitive testing on accumulating data (Thorlund 2011b; TSA 2011; Wetterslev 2017). To minimise random errors, we calculated the diversity-adjusted required information size (DARIS) (i.e. the number of participants needed in a meta-analysis to detect or reject a certain intervention effect) (Wetterslev 2008; Wetterslev 2009). The DARIS calculation accounts for the heterogeneity present in the meta-analysis. In our meta-analysis, the DARIS was based on the assumption of a plausible RR reduction of 20% (Wetterslev 2008). The underlying assumption of Trial Sequential Analysis is that significance testing may be performed each time a new trial is added to the meta-analysis. We added the trials according to the year of publication, and if more than one trial was published in a year, we added trials alphabetically according to the family name of the first author. On the basis of the risk for type I (5%) and type II (20%) errors, the chosen RR, the proportion with the outcome in the control group, and the observed heterogeneity, we calculated the DARIS and we constructed the trial sequential monitoring boundaries for benefits and harms (Brok 2008; Wetterslev 2008; Brok 2009; Thorlund 2009; Wetterslev 2009; Thorlund 2010; Wetterslev 2017). These boundaries determine the statistical inference one may draw regarding the cumulative meta-analysis that has not reached the required information size. If the cumulative Z-curve crosses the trial sequential monitoring boundary for benefit or harm before the required information size is reached in a cumulative meta-analysis, firm evidence may have been established and further trials may be superfluous. On the other hand, if the sequential monitoring boundaries are not surpassed and the trial monitoring boundaries for futility are not crossed, it is most probably necessary to continue doing trials in order to detect or reject a certain intervention effect. We used as default a type I error of 5%, type II error of 20%, and a DARIS as found in the conventional meta-analysis unless otherwise stated (Wetterslev 2008; Thorlund 2011a).

Subgroup analysis and investigation of heterogeneity

We performed the following pre-defined subgroup analyses.
- Different immunosuppressive agents.
- Co-interventions: comparing the intervention effect of trials with one, two, or three co-interventions.
- Duration of treatment with glucocorticosteroids.

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients (Review)   **10**

Copyright © 2018 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Trials before the year 2000 compared to trials in and after the year 2000 (since immunosuppression protocols have changed notably since 2000).

We were unable to perform the following pre-defined subgroup analyses due to lack of evidence.
- Trials at low risk of bias compared to trials at high risk of bias.
- Paediatric compared to adult liver transplantation.
- Time between transplantation and start of glucocorticosteroid administration, determined by the median time.
- Different indications for transplant.

Sensitivity analysis

We determined potential sensitivity analyses when we assessed our results to examine the robustness of our findings.

Zero event trials

Review Manager 5 software is unable to handle trials with zero events in both intervention groups when meta-analyses are performed as risk ratios or odds ratios. It seems unjustified and unreasonable to exclude zero event trials (Keus 2009), and potentially create the risk of inflating the magnitude of the pooled treatment effects. Therefore, we also performed a random-effects meta-analysis with empirical continuity correction of 0.01 in zero event trials (Sweeting 2004; Keus 2009), using the R software (R 2017).

'Summary of findings' tables

We constructed a 'Summary of findings' table for the comparison glucocorticoid-free versus glucocorticoid-containing immunosuppression following liver transplantation, presenting data on all primary outcomes and assessing the quality of the evidence based on risk of bias, imprecision, indirectness, heterogeneity, and risk of publication bias. We used the software GRADEpro© (GRADEpro 2008) to create Summary of findings for the main comparison.

RESULTS

Description of studies

Results of the search

Our electronic searches identified 4893 references (Figure 1). Searching of bibliographies found 115 additional references. Exclusion of duplicates and irrelevant references left 17 completed randomised clinical trials published in a total of 70 publications (32 peer-reviewed journal articles, 37 conference abstracts, and one clinical trials registry listing) (see Characteristics of included studies; Characteristics of excluded studies). One of the randomised clinical trials was published in a conference abstract and did not provide sufficient numeric data to allow incorporation of these data into our meta-analysis (Zhong 2010). Of the 16 randomised clinical trials included in our meta-analysis, four of the trials were published only in peer-reviewed journals (Belli 1998; Chen 2007; Hu 2008; Ju 2012), eleven of the trials were published as both peer-reviewed journal articles and conference abstracts (Tisone 1999; Belli 2001; Pageaux 2004; Margarit 2005; Reggiani 2005; Llado 2006; Moench 2007; Vivarelli 2007; Lerut 2008; Pelletier 2013; Ramirez 2013), and one was published only as a conference abstract (Studenik 2005).

Included studies

We included 16 randomised clinical trials in our meta-analysis, of which 15 trials were two-armed trials and one was a three-armed trial (Belli 2001). An additional trial, published in conference abstracts, could not be included in the quantitative analysis as it did not describe the number of participants allocated to each arm of the trial (Zhong 2010). The abstract published data on 182 participants and it is not clear from the abstract if the trial had been completed at the time of the conference. The trial was anticipated to include a total of 300 participants according to the study record within the National Library of Medicine Clinical Trials Registry (Zhong 2010). It is not possible to extract accurate numeric data from the abstract. The abstract reports the percentage of participants in each group of the trial who develop each outcome, but it does not report how many participants are randomised to each arm. For this reason, for the remainder of our quantitative results, we refer to the 16 completed trials which can be incorporated into the quantitative analysis of this review.

The 16 trials included a total of 1347 participants in whom glucocorticosteroids were compared as follows: complete glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) versus short-term glucocorticosteroids was compared in 10 trials with a total of 782 participants (Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Studenik 2005; Llado 2006; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013); and short-term glucocorticosteroids versus long-term glucocorticosteroids were compared in six trials with a total of 565 participants (Belli 1998; Pageaux 2004; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008). The additional trial compared complete glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) versus an unspecified duration of glucocorticosteroids (Zhong 2010).

As stated, complete glucocorticosteroid avoidance (excluding intra-operative use or treatment of acute rejection) was used in the experimental group in 10 trials (Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Studenik 2005; Llado 2006; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013). These trials of complete post-transplant glucocorticosteroid avoidance allowed glucocorticosteroids during the perioperative period and for treatment of acute rejection. Seven trials used no glucocorticosteroids in the perioperative period (Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Llado 2006; Pelletier 2013; Ramirez 2013), two trials used 500 mg glucocorticosteroids in the perioperative period (Studenik 2005; Ju 2012), and one trial used 100 mg glucocorticosteroids in the perioperative period (Lerut 2008).

For the full details of glucocorticosteroid regimens (including doses, frequencies, durations, and tapers) for each arm in all 16 trials included in the meta-analysis and the trial included in the qualitative analysis see Characteristics of included studies.

Characteristics of the studies

Sixteen of the trials are published in English. One of the trials is published only in Mandarin (Hu 2008). Two of the trials have additional publications in languages other than English: one abstract is published in German (Moench 2007), and one article in Mandarin (Ju 2012).

Mean follow-up time was reported in 12 trials and varied from 13 months to 108 months (Belli 1998; Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Studenik 2005; Moench 2007; Vivarelli 2007; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013).

Four of the 17 trials were multicentre (Pageaux 2004; Llado 2006; Vivarelli 2007; Zhong 2010), and the remaining 13 were single centre (Belli 1998; Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Studenik 2005; Chen 2007; Moench 2007; Hu 2008; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013).

All 17 of the trials consisted of exclusively adult populations.

Mean age of the intervention groups was reported in 14 trials (Belli 1998; Tisone 1999; Pageaux 2004; Margarit 2005; Reggiani 2005; Llado 2006; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013). Mean age of the participants ranged from 42 to 58 years. Sex ratio of the participants was reported in 12 trials (Belli 1998; Tisone 1999; Pageaux 2004; Margarit 2005; Reggiani 2005; Llado 2006; Chen 2007; Moench 2007; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013). The total number of male participants in the 12 trials was 845 (73.0%) and the total number of female participants was 312 (27.0%).

All of the trials report the primary indications for transplantation. In 12 trials there were a variety of indications (Belli 1998; Tisone 1999; Pageaux 2004; Margarit 2005; Reggiani 2005; Studenik 2005; Llado 2006; Moench 2007; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013). Two trials exclusively included participants with hepatitis C virus (HCV) cirrhosis as the primary indication for transplantation, with a total of 71 participants (Belli 2001; Vivarelli 2007). Three trials exclusively included participants with hepatocellular carcinoma as the primary indication for transplantation (Chen 2007; Hu 2008; Zhong 2010). A total of 258 participants were reported as having HCV cirrhosis as the primary indication for transplantation, although there might have been more participants who had an alternative primary indication but were also HCV positive. Two trials published separate articles dealing with a cohort of HCV-positive participants including a total of 124 participants (Llado 2006; Lerut 2008). One trial described the outcomes of HCV-positive participants as a separate cohort within the main article, including a total of 35 participants (Margarit

2005).

Eight trials reported on the type of donor used. In six of the trials, the grafts were obtained exclusively from deceased (cadaveric) donors (Pageaux 2004; Llado 2006; Vivarelli 2007; Hu 2008; Ju 2012; Ramirez 2013). In two of the trials, the grafts were obtained from both deceased (cadaveric) and living donors (Moench 2007; Lerut 2008), but in one of these trials the deceased donors were exclusively donors after brain death (Moench 2007). The remaining trials did not report on type of donor used (Belli 1998; Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Studenik 2005; Chen 2007; Zhong 2010; Pelletier 2013).

Fifteen trials reported on the duration of glucocorticosteroid administration in the glucocorticosteroid-containing arm. One trial administered glucocorticosteroids for 64 days in the glucocorticosteroid-containing arm (Lerut 2008). Seven trials administered glucocorticosteroids for three months in the glucocorticosteroid-containing arm (Tisone 1999; Belli 2001; Margarit 2005; Reggiani 2005; Llado 2006; Hu 2008; Ju 2012). One trial administered glucocorticosteroids for three to six months in the glucocorticosteroid-containing arm (Pelletier 2013). Two trials administered glucocorticosteroids for six months in the glucocorticosteroid-containing arm (Moench 2007; Ramirez 2013). One trial administered glucocorticosteroids for nine months in the glucocorticosteroid-containing arm (Studenik 2005). One trial administered glucocorticosteroids for 25 months in the glucocorticosteroid-containing arm (Vivarelli 2007). Two trials administered glucocorticosteroids indefinitely in the glucocorticosteroid-containing arm (Belli 1998; Chen 2007). Two trials did not report the duration of glucocorticosteroid administration in the glucocorticosteroid-containing arm (Pageaux 2004; Zhong 2010). For the subgroup analyses on duration of glucocorticosteroid administration, we grouped the trials together as 'less than or equal to three months', 'greater than three and up to six months', and 'greater than six months'.

Five trials were commenced before 2000 (Belli 1998; Tisone 1999; Belli 2001; Pageaux 2004; Margarit 2005), and the remaining 12 trials were commenced from 2000 onwards (Reggiani 2005; Studenik 2005; Llado 2006; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008; Zhong 2010; Ju 2012; Pelletier 2013; Ramirez 2013).

Three trials reported no missing data at latest follow-up and provided adequate data to explain if any participants were not included in the analysis so that these participants could be included in the meta-analysis (Moench 2007; Lerut 2008; Ramirez 2013). One of these trials reported 12/124 participants refusing biopsy at five years (Lerut 2008). Nine trials did not report the number of dropouts adequately (Tisone 1999; Belli 2001; Reggiani 2005; Studenik 2005; Llado 2006; Chen 2007; Zhong 2010; Ju 2012; Pelletier 2013). Five trials reported at least one participant lost to follow-up, with a total of 25/642 participants in the glucocorticosteroid avoidance or withdrawal group lost to follow-up and 21/651 participants in the glucocorticosteroid-containing group

lost to follow-up. One trial reported two dropouts in each group (Belli 1998). One trial reported three dropouts in the glucocorticosteroid withdrawal group and four dropouts in the glucocorticosteroid-containing group (Hu 2008). One trial reported one dropout in the glucocorticosteroid withdrawal group and no dropouts in the glucocorticosteroid-containing group (Margarit 2005). One trial reported 19 dropouts in the glucocorticosteroid withdrawal group and 12 dropouts in the glucocorticosteroid-containing group (Pageaux 2004). One trial reported no dropouts in the glucocorticosteroid withdrawal group and three dropouts in the glucocorticosteroid-containing group (Vivarelli 2007). One trial excluded 16 participants from the reported acute rejection rate due to treatment failure (Belli 1998). Our protocol stated that all available data should be analysed using the intention-to-treat principle (Fairfield 2014). Therefore, we included the three participants in the glucocorticosteroid withdrawal group and 13 participants in the long-term glucocorticosteroid group as 'lost to follow-up' for the outcome 'acute rejection'.

Concomitant immunosuppression

All trials reported on concomitant immunosuppression, but this varied between trials. Of the 17 trials all used a calcineurin inhibitor with 11 using tacrolimus (Margarit 2005; Reggiani 2005; Studenik 2005; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013), and six used cyclosporine A (Belli 1998; Tisone 1999; Belli 2001; Pageaux 2004; Llado 2006; Zhong 2010). One trial replaced tacrolimus with sirolimus when clinically indicated (Ju 2012). Of the 11 trials in which tacrolimus was used, five of the trials used no other concomitant immunosuppression as described in the intervention groups (Margarit 2005; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008) (see Characteristics of included studies).

Seven of the 17 trials used an antiproliferative agent, with six trials using mycophenolate mofetil (Reggiani 2005; Studenik 2005; Chen 2007; Ju 2012; Pelletier 2013; Ramirez 2013), and one trial using azathioprine (Tisone 1999). All of the trials that used mycophenolate mofetil also used tacrolimus and the one trial that used azathioprine used cyclosporine A.

Induction therapy with a non-glucocorticosteroid agent was used in nine of the trials. Two trials used rabbit antithymocyte globulin (RATG) (Belli 1998; Belli 2001); six trials used basiliximab (Pageaux 2004; Llado 2006; Zhong 2010; Ju 2012; Pelletier 2013; Ramirez 2013); and one trial used daclizumab (Studenik 2005). Concomitant immunosuppression consisted of a calcineurin inhibitor used in combination with an antiproliferative agent in three trials (Tisone 1999; Reggiani 2005; Chen 2007). Concomitant immunosuppression consisted of a calcineurin inhibitor used in combination with induction therapy in five trials (Belli 1998; Belli 2001; Pageaux 2004; Llado 2006; Zhong 2010). Concomitant immunosuppression consisted of triple therapy with a calcineurin inhibitor, an antiproliferative agent, and induction therapy in four

trials ([Studenik 2005](); [Ju 2012](); [Pelletier 2013](); [Ramirez 2013]()).

Excluded studies

We excluded 27 trials after reading the full text of the articles. These articles mostly related to randomised clinical trials but did not assess glucocorticosteroid-containing versus glucocorticosteroid-free immunosuppression. We explained the reasons for their exclusion in [Characteristics of excluded studies]().

Risk of bias in included studies

Trial methodology was only adequately reported in two of the trials ([Moench 2007](); [Lerut 2008]()) (see [Figure 2](); [Figure 3]()). We considered all 17 of the trials to be at high risk of bias as we considered one or more of the bias components of each trial to be at unclear risk of bias due to inadequately reported methodology or at high risk of bias ([Belli 1998](); [Tisone 1999](); [Belli 2001](); [Pageaux 2004](); [Margarit 2005](); [Reggiani 2005](); [Studenik 2005](); [Llado 2006](); [Chen 2007](); [Moench 2007](); [Vivarelli 2007](); [Hu 2008](); [Lerut 2008](); [Zhong 2010](); [Ju 2012](); [Pelletier 2013](); [Ramirez 2013]()).

Figure 2. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.
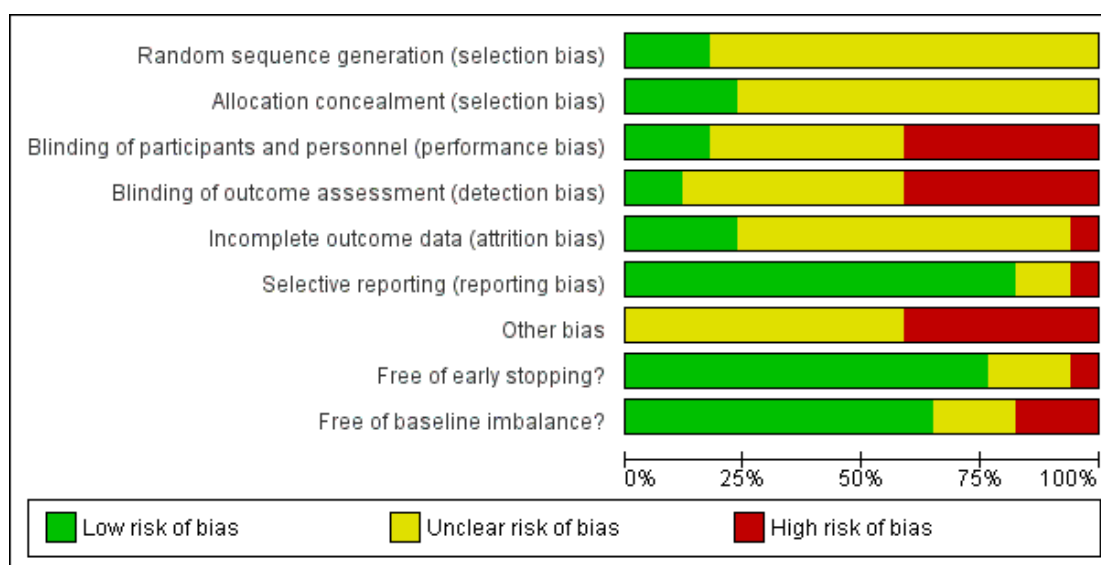

Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Allocation

Generation of the allocation sequence was adequately reported in three trials (Tisone 1999; Ju 2012; Ramirez 2013), and inadequately reported in 14 trials (Belli 1998; Belli 2001; Pageaux 2004; Margarit 2005; Reggiani 2005; Studenik 2005; Llado 2006; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008; Zhong 2010; Pelletier 2013).

Allocation concealment was adequate in four trials (Margarit 2005; Moench 2007; Lerut 2008; Pelletier 2013), and inadequately reported in 13 trials (Belli 1998; Tisone 1999; Belli 2001; Pageaux 2004; Reggiani 2005; Studenik 2005; Llado 2006; Chen 2007; Vivarelli 2007; Hu 2008; Zhong 2010; Ju 2012; Ramirez 2013).

Blinding

Three trials reported accurately and applied adequate methods for blinding of participants (Pageaux 2004; Moench 2007; Lerut 2008). One of these trials blinded participants but not outcome assessors (Moench 2007). Seven trials did not report on blinding (Belli 1998; Belli 2001; Studenik 2005; Chen 2007; Hu 2008; Zhong 2010; Ju 2012), and seven trials did not perform blinding (Tisone 1999; Margarit 2005; Reggiani 2005; Llado 2006; Vivarelli 2007; Pelletier 2013; Ramirez 2013).

Incomplete outcome data

In four trials, either no data were missing or missing data were adequately reported and unlikely to have influenced outcome results (Moench 2007; Vivarelli 2007; Lerut 2008; Ramirez 2013). In the remaining 13 trials missing data were inadequately addressed (Belli 1998; Tisone 1999; Belli 2001; Pageaux 2004; Margarit 2005; Reggiani 2005; Studenik 2005; Llado 2006; Chen 2007; Hu 2008; Zhong 2010; Ju 2012; Pelletier 2013). In one trial, a participant was excluded following a re-transplant and death 10 days later (Ramirez 2013); as this occurred after randomisation, we had to re-enter the participant into the analysis for inclusion in the meta-analysis. In one trial, three participants were excluded due to early death (two participants) and positive cross-match (one participant) (Margarit 2005); as this occurred after randomisation, we had to re-enter the participants into the analysis for inclusion in the meta-analysis: we added one case of mortality to each group and one case of missing data to the glucocorticosteroid-free group as well as we adjusted the totals accordingly. The trial did not make comment on any other missing data. One trial excluded nine participants due to early death (five participants) and ABO-blood group incompatibility (four participants) (Ju 2012), reporting on the original allocated groups of the deaths but not the ABO-blood group incompatibility; as this occurred after randomisation, we had to re-enter the participants who suffered from early

mortality into the analysis for inclusion in the meta-analysis. One trial excluded eight participants due to early death (three participants), graft loss (two participants), change to alternative primary immunosuppressant (two participants), and de novo hepatitis B virus (HBV) infection (one participant) (Vivarelli 2007); as this occurred after randomisation, we had to re-enter the participants into the analysis for inclusion in the meta-analysis: we added the cases of mortality and graft loss to the intervention groups accordingly, and we counted the change in immunosuppressant and HBV infection as loss to follow-up. As some of these participants were randomised but excluded from the analysis, they might not have been included in the demographic data except where authors had provided relevant details. In the three-armed trial, six participants died and one developed portal vein thrombosis (Belli 2001). The participants were split between the three arms (two in the standard therapy arm; three in the glucocorticosteroid-free arm; and two in the glucocorticosteroid-free and ribavirin arm), but which group the participant with portal vein thrombosis was in and which groups the deaths occurred in was not reported. We could not include the outcome of mortality in this trial in the main analysis, but it was possible to include it in the best-worst, worst-best analysis: the number of participants suffering from mortality is either one or two in the standard therapy arm and either two or three in the glucocorticosteroid-free arm, and we used these values in the analysis.

Missing summary data

One trial reported mean arterial pressure, serum cholesterol, and fasting blood glucose, but it did not provide a standard deviation or range (Ramirez 2013). Furthermore, in this trial, no exact P values were reported, but P values were described as "NS" (not significant) (Ramirez 2013). These results are included in this review.

Selective reporting

We had no access to the protocols for any of the trials other than the trial only included in qualitative analysis (Zhong 2010). One trial was published only in an abstract, so no comment on selective reporting could be made (Studenik 2005). Of the 15 remaining trials, 14 reported expected clinical outcome measures or outcomes as specified in the methods section of the article (Belli 1998; Belli 2001; Pageaux 2004; Margarit 2005; Reggiani 2005; Llado 2006; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Lerut 2008; Ju 2012; Pelletier 2013; Ramirez 2013). One trial did not report expected outcome of hypertension described in the introduction and discussion section of the article (Tisone 1999).

Other potential sources of bias

Seven trials reported part or full industry sponsorship (Pageaux 2004; Llado 2006; Moench 2007; Vivarelli 2007; Lerut 2008; Pelletier 2013; Ramirez 2013). Four trials reported sponsorship exclusively from other sources (Margarit 2005; Hu 2008; Zhong 2010; Ju 2012). The remaining six trials did not report on sponsorship (Belli 1998; Tisone 1999; Belli 2001; Reggiani 2005; Studenik 2005; Chen 2007).

Three of the 17 trials reported a required sample size calculation (Llado 2006; Moench 2007; Lerut 2008), whilst the remainder did not (Belli 1998; Tisone 1999; Belli 2001; Pageaux 2004; Margarit 2005; Reggiani 2005; Studenik 2005; Chen 2007; Vivarelli 2007; Hu 2008; Zhong 2010; Ju 2012; Pelletier 2013; Ramirez 2013). Thirteen of the trials appeared to be free from early stopping. One of the trials was stopped early following an interim analysis. The stopping criteria were not described in the trial that was stopped early (Reggiani 2005). Two trials did not report adequately on early stopping (Studenik 2005, Chen 2007). One trial was published only as a conference abstract and reported only preliminary findings; the data are not included in this review due to inadequate reporting of participants in each intervention group (Zhong 2010).

Eleven of the 17 trials are free from baseline imbalance (Belli 1998; Tisone 1999; Pageaux 2004; Studenik 2005; Llado 2006; Chen 2007; Moench 2007; Vivarelli 2007; Hu 2008; Pelletier 2013; Ramirez 2013). Three trials reported on significant baseline imbalance (Margarit 2005; Reggiani 2005; Lerut 2008). In three of the trials, the baseline characteristics were inadequately reported to allow comparison (Belli 2001; Zhong 2010; Ju 2012).

Effects of interventions

See: **Summary of findings for the main comparison** Glucocorticosteroid avoidance or withdrawal compared to glucocorticosteroid-based immunosuppression for liver transplanted patients

See Summary of findings for the main comparison for the effects of glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression for liver transplanted patients.

Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression

All-cause mortality

Fifteen trials with 1323 participants reported adequately on mortality, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (128/659 (19%) versus 110/664 (17%); risk ratio (RR) 1.15, 95% confidence interval (CI) 0.93 to 1.44; low-quality evidence; Analysis 1.1). One trial reported the total number of deaths and a portal vein thrombosis as a composite outcome for the entire trial but did not adequately describe to which group the portal vein thrombosis and the deaths belonged (Belli 2001). As a result of this, the trial could not be included for this outcome except in the best-worst and worst-best analyses (Analysis 8.1; Analysis 9.1). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3520 participants was not obtained (Figure 4).

Figure 4.   Mortality: glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid containing immunosuppression. Trial Sequential Analysis of the effect of glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression on mortality based on 15 trials with 1323 participants. The diversity-adjusted required information size (DARIS) of 3520 participants was calculated on the basis of type I error of 5%, type II error of 20% and risk reduction of 20%, and information size was adjusted for diversity (0%). The cumulative Z-curve does not cross trial sequential monitoring boundaries, and the required information size was not reached.
Graft loss including death

Eleven trials with 1002 participants reported on graft loss including death, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (118/631 (19%) versus 97/638 (15%); RR 1.15, 95% CI 0.90 to 1.46; low-quality evidence; Analysis 1.2). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 2423 participants was not obtained (Figure 5).

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients (Review)   **20**

Copyright © 2018 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 5. Graft loss including death: glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid containing immunosuppression. Trial Sequential Analysis of the effect of glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression on graft loss including death based on 11 trials with 1002 participants. The diversity-adjusted required information size (DARIS) was calculated on the basis of type I error of 5%, type II error of 20% and risk reduction of 20%, and information size was adjusted for diversity (0%). The cumulative Z-curve does not cross trial sequential monitoring boundaries, and the required information size was not reached.
Acute rejection

Acute rejection was defined as the total number of participants who experienced one or more rejection episodes. Sixteen trials with 1347 participants reported on acute rejection, and acute rejection was statistically significantly more frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (150/670 (22%) versus 117/677 (17%); RR 1.33, 95% CI 1.08 to 1.64; low-quality evidence; Analysis 1.3). However, Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3520 participants was not obtained (Figure 6).

Figure 6. Acute rejection: glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid containing immunosuppression. Trial Sequential Analysis of the effect of glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression on acute rejection based on 16 trials with 1347 participants. The diversity-adjusted required information size (DARIS) was calculated on the basis of type I error of 5%, type II error of 20% and risk reduction of 20%, and information size was adjusted for diversity (0%). The cumulative Z-curve does not cross trial sequential monitoring boundaries, and the required information size was not reached.
Infection

Eight trials with 778 participants reported adequately on infection, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (120/382 (31%) versus 142/396 (36%); RR 0.88, 95% CI 0.73 to 1.05; very low-quality evidence; Analysis 1.4). Infection was defined in each of the eight trials as the number of participants who experienced one or more infection. Two other trials reported the total number of cases of infection including those with multiple episodes of infection (Margarit 2005; Lerut 2008). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3222 participants was not obtained.

Other adverse events

No trials reported on adverse events. A number of trials reported "deaths due to an adverse event" or separate adverse events such as the development of de novo diabetes mellitus but none of the trials reported the total number of adverse events.

Chronic rejection

Nine trials with 974 participants reported on chronic rejection, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid containing immunosuppression (16/482 (3%) versus 15/492 (3%); RR 1.08, 95% CI 0.56 to 2.10; very low-quality evidence; Analysis 1.5). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 26,534 participants was not obtained.

Glucocorticosteroid-resistant rejection

Glucocorticosteroid-resistant rejection was defined as the total number of participants who experienced one or more glucocorticosteroid-resistant rejections. Ten trials with 1020 participants reported on glucocorticosteroid-resistant rejection, and glucocorticosteroid-resistant rejection was statistically significantly more frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (27/505 (5%) versus 13/515 (3%); RR 2.14, 95% CI 1.13 to 4.02; very low-quality evidence; Analysis 1.6). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 2190 participants was not obtained.

Diabetes mellitus

Twelve trials with 1185 participants reported on diabetes mellitus, and diabetes mellitus was not significantly different when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (125/588 (21%) versus 156/597 (26%); RR 0.82, 95% CI 0.64 to 1.07; low-quality evidence) when we applied the random-effects model. However, when we applied the fixed-effect model, diabetes mellitus was statistically significantly less frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (RR 0.81, 95% CI 0.66 to 0.99; low-quality evidence; Analysis 1.7). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3348 participants was not obtained.

Cytomegalovirus (CMV) infection

CMV infection was defined as the development of CMV disease requiring treatment. Seven trials with 786 participants reported on CMV infection, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (28/387 (7%) versus 38/399 (10%); RR 0.74, 95% CI 0.48 to 1.16; low-quality evidence; Analysis 1.8). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 6429 participants was not obtained.

Hepatitis C virus (HCV) recurrence

Ten trials with 477 participants reported on HCV recurrence, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (159/232 (69%) versus 162/245 (66%); RR 1.03, 95% CI 0.92 to 1.15; very low-quality evidence; Analysis 1.9). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve but the required information size of 435 participants was obtained, meaning that we can exclude a relative risk reduction of 20% or more.

Malignancy

Three trials with 528 participants reported on de novo malignancy, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (3/258 (1%) versus 7/270 (3%); RR 0.52, 95% CI 0.16 to 1.74; very low-

quality evidence; Analysis 1.10). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 22,911 participants was not obtained.

Post-transplant lymphoproliferative disorder

Two trials with 330 participants reported on post-transplant lymphoproliferative disorder, and overall we found no statistically significant difference when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (3/162 (2%) versus 1/168 (1%); RR 2.39, 95% CI 0.36 to 15.95; very low-quality evidence; Analysis 1.11). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 70,005 participants was not obtained.

Renal function

No trials reported on renal failure requiring dialysis.
Four trials with 447 participants reported on renal insufficiency, and overall we found no statistically significant difference when glucocorticosteroid avoidance was compared with glucocorticosteroid-containing immunosuppression (67/216 (31%) versus 77/231 (33%); RR 0.93, 95% CI 0.73 to 1.19; very low-quality evidence; Analysis 1.12). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3735 participants was not obtained.
No trials reported on estimated glomerular filtration rate.
Four trials with 309 participants reported on creatinine (mg/dL), and creatinine was not significantly different when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (MD 0.01 mg/dL, 95% CI -0.21 to 0.23; very low-quality evidence) when we applied the random-effects model. However, when we applied the fixed-effect model, creatinine was statistically significantly raised when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (MD 0.11 mg/dL, 95% CI 0.07 to 0.16; very low-quality evidence; Analysis 1.13).

De novo autoimmune hepatitis

No trials reported on de novo autoimmune hepatitis.

Hypertension

Ten trials with 1098 participants reported on hypertension, and hypertension was statistically significantly less frequent when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (157/543 (29%) versus 210/555 (38%); RR 0.76, 95% CI 0.65 to

0.90; low-quality evidence; Analysis 1.14). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 3409 participants was not obtained.

Hyperlipidaemia

Four trials with 400 participants reported on hyperlipidaemia, and overall we found no statistically significant difference when glucocorticosteroid avoidance was compared with glucocorticosteroid-containing immunosuppression (13/197 (7%) versus 18/203 (9%); RR 0.75, 95% CI 0.38 to 1.48; very low-quality evidence; Analysis 1.15). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 7214 participants was not obtained.

Cholesterol

Five trials with 556 participants reported on serum cholesterol (mg/dL), and serum cholesterol was statistically significantly reduced when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (mean difference (MD) -18.49 mg/dL, 95% CI -22.02 to -14.96; very low-quality evidence; Analysis 1.16).
Two trials with 266 participants reported on hypercholesterolaemia, and hypercholesterolaemia was not significantly different when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression (16/134 (12%) versus 28/132 (21%); RR 0.56, 95% CI 0.32 to 1.00; very low-quality evidence; Analysis 1.17). Trial Sequential Analysis showed that trial sequential monitoring boundaries were not broken by the cumulative Z-curve and the required information size of 20,334 participants was not obtained.

Health-related quality of life

No trials reported on health-related quality of life.

Zero event trial correction

Trials with zero events in both intervention groups were found in several of the analyses. For all of these analyses, we applied a random-effects meta-analysis with empirical continuity correction of 0.01 using the R software (R 2017). This correction of zero event trials resulted in none of the analyses yielding statistically significantly different results (i.e. all statistically significant differences in results between the groups remained statistically significantly different after zero event trial correction, and all non-statistically significant differences in results between the groups remained non-statistically significantly different after zero event trial correction).

Subgroup analyses

We were not able to perform our predefined subgroup analysis on trials at low risk of bias compared to trials at high risk of bias, as we considered none of the trials included in the review to be at low risk of bias.

We were not able to perform our predefined subgroup analysis on trials with paediatric participants compared to trials with adult participants, as all of the trials included in the review recruited exclusively adult participants.

We were not able to perform our predefined subgroup analysis on the median time between transplantation and the commencement of glucocorticosteroid administration, as none of the trials included in the review reported this in their methodology.

We performed subgroup analyses on glucocorticosteroid avoidance compared to glucocorticosteroid withdrawal (Analysis 1.1 through Analysis 1.17). Tests for subgroup differences between glucocorticosteroid avoidance and glucocorticosteroid withdrawal were not statistically significantly different for most outcomes, except for the outcomes 'Infection', 'Creatinine' and 'Hypercholesterolaemia'. We found a statistically significant interaction for infection (P = 0.04). This difference between glucocorticosteroid avoidance and glucocorticosteroid withdrawal is caused by one trial using glucocorticosteroid withdrawal that caused significantly fewer infections in the glucocorticosteroid avoidance or withdrawal group compared to trials in which glucocorticosteroid avoidance was used (RR 0.12, 95% CI 0.02 to 0.89). We found a statistically significant interaction for creatinine (P = 0.0004). This difference between glucocorticosteroid avoidance and glucocorticosteroid withdrawal is caused by two trials using glucocorticosteroid withdrawal that caused significantly lower creatinine in the glucocorticosteroid avoidance or withdrawal group compared to trials in which glucocorticosteroid avoidance was used (MD -0.06 mg/dL, 95% CI -0.16 to 0.05). We found a statistically significant interaction for hypercholesterolaemia (P = 0.008). This difference is caused by one trial reporting no statistically significant difference and one trial reporting statistically significantly lower rates of hypercholesterolaemia in the glucocorticosteroid avoidance and withdrawal arm. There are only a small number of studies reporting on infection, creatinine, and hypercholesterolaemia.The difference observed between subgroups for these outcomes may therefore be due to a factor other than glucocorticosteroid use.

We performed subgroup analyses on type of calcineurin inhibitor used (tacrolimus or cyclosporine A) (Analysis 2.1 through Analysis 2.16). Tests for subgroup differences between type of calcineurin inhibitor used as a co-intervention were not statistically significantly different for most outcomes, except for the outcome 'Creatinine' for which we found a statistically significant interaction (P < 0.00001). This difference between type of calcineurin inhibitor used as co-intervention is caused by one trial using the calcineurin inhibitor tacrolimus, which caused significantly higher serum creatinine levels in the glucocorticosteroid avoidance or withdrawal group compared to trials in which cyclosporine A was used (MD

0.25 mg/dL, 95% CI 0.19 to 0.31).

We performed subgroup analyses on type of antiproliferative agent (azathioprine or mycophenolate mofetil) compared to no antiproliferative agent (Analysis 3.1 through Analysis 3.14). Tests for subgroup differences between the type of antiproliferative agent used as a co-intervention when compared to no antiproliferative agent were not statistically significantly different for most outcomes, except for the outcome 'Creatinine', for which we found a statistically significant interaction (P < 0.00001). This difference between the type of antiproliferative agent used as a co-intervention is caused by one trial using the antiproliferative agent mycophenolate mofetil, which caused significantly higher serum creatinine in the glucocorticosteroid avoidance or withdrawal group compared to trials in which azathioprine or no antiproliferative agent were used (MD 0.25 mg/dL, 95% CI 0.19 to 0.31).

We performed subgroup analyses on type of induction agent (basiliximab, daclizumab, or rabbit antithymocyte globulin) compared to no induction agent (Analysis 4.1 through Analysis 4.16). Tests for subgroup differences between the type of induction therapy used as a co-intervention when compared to no induction agent were not statistically significantly different for most outcomes, except for the outcomes 'Infection', 'Creatinine', 'Hypertension' and 'Cholesterol'. We found a statistically significant difference for infection (P = 0.04). This difference between the type of induction therapy used as a co-intervention is caused by the induction agent rabbit antithymocyte globulin, which caused significantly fewer infections in the glucocorticosteroid avoidance or withdrawal group compared to trials in which basiliximab or no induction agents were used (RR 0.12, 95% CI 0.02 to 0.89). We found a statistically significant interaction for serum creatinine (P < 0.00001). This difference between the type of induction therapy used as a co-intervention is caused by the induction agent basiliximab, which caused significantly higher serum creatinine in the glucocorticosteroid avoidance or withdrawal group compared to trials in which no induction agent was used (MD 0.25 mg/dL, 95% CI 0.19 to 0.31). We found a statistically significant interaction for hypertension (P = 0.03). This difference between the type of induction therapy used as a co-intervention is caused by the induction agent rabbit antithymocyte globulin, which caused significantly lower rates of hypertension in the glucocorticosteroid avoidance or withdrawal group compared to trials in which basiliximab or no induction agent were used (RR 0.30, 95% CI 0.16 to 0.57). We found a statistically significant interaction for serum cholesterol (P = 0.0001). This difference between the type of induction therapy used as a co-intervention is caused in part by the induction agent rabbit antithymocyte globulin, which caused significantly lower serum cholesterol in the glucocorticosteroid avoidance or withdrawal group compared to trials in which basiliximab was used (MD -70.00 mg/dL, 95% CI -101.17 to -39.83) and in part by one trial that did not use an induction agent, which caused significantly lower serum cholesterol in the glucocorticosteroid avoidance or withdrawal group compared to trials in which

basiliximab was used (MD -146.00 mg/dL, 95% CI -192.16 to -99.84).

We performed subgroup analyses on the number of co-interventions given (monotherapy, dual therapy, or triple therapy) (Analysis 5.1 through Analysis 5.16). Tests for subgroup differences between the number of co-interventions given were not statistically significantly different for most outcomes, except for the outcomes 'Creatinine' and 'Cholesterol'. We found a statistically significant interaction for serum creatinine (P < 0.00001). This difference between the number of co-interventions given is caused by the use of triple therapy in one trial, which caused significantly higher serum creatinine in the glucocorticosteroid avoidance or withdrawal group compared to monotherapy or triple therapy (MD 0.25 mg/dL, 95% CI 0.19 to 0.31). We found a statistically significant difference for serum cholesterol (P < 0.00001). This difference between the number of co-interventions given is caused by the use of monotherapy in one trial, which caused significantly higher serum cholesterol in the glucocorticosteroid avoidance or withdrawal group compared to dual therapy or triple therapy (MD 35.00 mg/dL, 95% CI 12.31 to 57.69).

We performed subgroup analyses on the duration of glucocorticosteroid use in the longer glucocorticosteroid taper arm or the long-term glucocorticosteroid arm (up to three months of glucocorticosteroids; greater than three months and up to six months of glucocorticosteroids; or greater than six months of glucocorticosteroids) (Analysis 6.1 through Analysis 6.13). One trial did not report on the duration of glucocorticosteroid use in the glucocorticosteroid-containing arm and was not included in this sub-analysis (Pageaux 2004). Tests for subgroup differences between duration of glucocorticosteroid use in the glucocorticosteroid-containing arm were not statistically significantly different for most outcomes, except for the outcomes 'Creatinine', 'Hypertension', 'Cholesterol' and 'Hypercholesterolaemia'. We found a statistically significant difference for serum creatinine (P = 0.00001). This difference between the duration of glucocorticosteroid use is caused by one trial using three to six months of glucocorticosteroids in the glucocorticosteroid-containing group, which caused significantly higher serum creatinine in the glucocorticosteroid avoidance or withdrawal group compared to trials using two to three months of glucocorticosteroids and more than six months of glucocorticosteroids in the glucocorticosteroid-containing arm (MD 0.25 mg/dL, 95% CI 0.19 to 0.31). We found a statistically significant difference for hypertension (P = 0.001). This difference between duration of glucocorticosteroid use in the glucocorticosteroid-containing arm is caused, in part, by one trial which used long-term glucocorticosteroid in the glucocorticosteroid-containing arm, which caused significantly lower rates of hypertension in the glucocorticosteroid avoidance or withdrawal group compared to trials using two to three months or three to six months of glucocorticosteroids in the glucocorticosteroid-containing arm (RR 0.30, 95% CI 0.16 to 0.57). We found a statistically significant difference for cholesterol (P = 0.002). This difference between du-

ration of glucocorticosteroid use in the glucocorticosteroid-containing arm is caused by two trials using long-term glucocorticosteroids in the glucocorticosteroid-containing arm, which caused significantly lower serum cholesterol in the glucocorticosteroid avoidance or withdrawal group compared to trials using two to three months or three to six months of glucocorticosteroids in the glucocorticosteroid-containing arm (MD -92.75 mg/dL, 95% CI -118.01 to -67.50). We found a statistically significant interaction for hypercholesterolaemia (P = 0.008). This difference between duration of glucocorticosteroid use in the glucocorticosteroid-containing is due to the small number of trials reporting on hypercholesterolaemia, with one trial reporting no statistically significant difference and one trial reporting statistically significantly lower rates of hypercholesterolaemia in the glucocorticosteroid avoidance and withdrawal arm. The difference observed between subgroups for hypercholesterolaemia may therefore be due to a factor other than duration of glucocorticosteroid use.

We performed subgroup analyses on trials commenced before the year 2000 and trials commenced from 2000 onwards (Analysis 7.1 through Analysis 7.16). Tests for subgroup differences between trials commenced before 2000 and trials commenced from 2000 onwards were not statistically significantly different for most outcomes, except for the outcomes 'Creatinine', 'Hypertension', and 'Cholesterol'. We found a statistically significant interaction for creatinine (P < 0.00001). This difference between trials commenced before 2000 and trials commenced from 2000 onwards is caused by one trial started after 2000, which caused significantly higher serum creatinine in the glucocorticosteroid avoidance or withdrawal group compared to a trial started before 2000 (MD 0.25 mg/dL, 95% CI 0.19 to 0.31). We found a statistically significant difference for hypertension (P = 0.03). This difference between trials commenced before 2000 and trials commenced from 2000 onwards is caused by one trial started before 2000, which caused significantly lower rates of hypertension in the glucocorticosteroid avoidance or withdrawal group compared to trials started after 2000 (RR 0.30, 95% CI 0.16 to 0.57). We found a statistically significant difference for cholesterol (P = 0.03). This difference between trials commenced before 2000 and trials commenced from 2000 onwards is caused by one trial started before 2000, which caused significantly lower serum cholesterol in the glucocorticosteroid avoidance or withdrawal group compared to trials started after 2000 (MD -70.00 mg/dL, 95% CI -101.17 to -39.83).

The statistically significant interactions in serum creatinine and serum cholesterol between many of the subgroups are unlikely to reflect actual differences between the subgroups. Instead they are likely to reflect the relatively small number of trials that report on these outcomes and the considerable heterogeneity influencing these outcomes.

Best-worst and worst-best analyses

We found trials with missing data in several of the analyses. For each of these analyses, we applied a best-worst analysis and a worst-best analysis.

Best-worst analyses

The best-worst analyses (best results possible for glucocorticosteroid avoidance or withdrawal) did not yield statistically significantly different results from the conventional meta-analysis except for acute rejection, infection, glucocorticosteroid-resistant rejection, CMV infection, malignancy, post-transplant lymphoproliferative disorder, and hyperlipidaemia (Analysis 8.1 through Analysis 8.12). We observed no statistically significant difference in the best-worst analyses for acute rejection (RR 1.04, 95% CI 0.85 to 1.26) or glucocorticosteroid-resistant rejection (RR 1.00, 95% CI 0.61 to 1.65) when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression. We found statistically significant reductions in the best-worst analyses for infection (RR 0.80, 95% CI 0.67 to 0.96), CMV infection (RR 0.57, 95% CI 0.37 to 0.87), malignancy (RR 0.21, 95% CI 0.07 to 0.61), post-transplant lymphoproliferative disorder (RR 0.24, 95% CI 0.07 to 0.85), and hyperlipidaemia (RR 0.40, 95% CI 0.21 to 0.73) when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression. However, it is unlikely that all 12 participants lost to follow-up in the glucocorticosteroid-containing immunosuppression arm of Pageaux 2004 suffered from malignancy and post-transplant lymphoproliferative disorder. We found no statistically significant differences between the best-worst analyses and the conventional meta-analysis for mortality, graft loss including death, chronic rejection, diabetes mellitus, or hypertension when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression.

Worst-best analyses

The worst-best analyses (worst results possible for glucocorticosteroid avoidance or withdrawal) did not yield statistically significantly different results from the conventional meta-analysis except for mortality, graft loss including death, chronic rejection, diabetes mellitus, malignancy, post-transplant lymphoproliferative disorder, hypertension, and hyperlipidaemia (Analysis 9.1 through Analysis 9.13). We observed no statistically significant difference in the worst-best analyses for diabetes mellitus (RR 0.95, 95% CI 0.79 to 1.15) or hypertension (RR 0.87, 95% CI 0.75 to 1.02) when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression. We found statistically significant increases in the worst-best analyses for mortality (RR 1.35, 95% CI 1.10 to 1.67), graft loss including death (RR 1.38, 95% CI 1.08 to 1.74), chronic rejection (RR 2.45, 95% CI 1.40 to 4.31), malignancy (RR 3.05, 95% CI 1.38 to 6.73), post-transplant lymphoproliferative disorder (RR

15.64, 95% CI 3.08 to 79.56), and hyperlipidaemia (RR 1.92, 95% CI 1.12 to 3.28) when the glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression. However, it is unlikely that all 19 participants lost to follow-up in the glucocorticosteroid withdrawal arm of Pageaux 2004 suffered from malignancy and post-transplant lymphoproliferative disorder. We found no statistically significant differences between the best-worst analyses and the conventional meta-analysis for acute rejection, infection, glucocorticosteroid-resistant rejection, CMV infection, or renal insufficiency when glucocorticosteroid avoidance or withdrawal was compared with glucocorticosteroid-containing immunosuppression.

Adverse events reported in non-randomised studies

Our search was primarily to identify randomised clinical trials and systematic reviews. However, the search returned multiple citations from quasi-randomised or non-randomised studies. In these studies, we searched for adverse events that were different to those reported in the randomised clinical studies in terms of number or type of adverse event. We were unable to find any unique adverse events in the non-randomised studies and we found no significant discrepancy in the rates of the adverse events reported in the randomised trials of this systematic review. We did not find any unique adverse events reported in the completed study that we were not able to incorporate to the meta-analysis (Zhong 2010).

Publication bias

We performed a linear regression test to explore funnel plot asymmetry for any outcomes reported in 10 or more trials (Egger 1997). We found no asymmetry for mortality, graft loss including death, acute rejection, glucocorticosteroid-resistant rejection, or hepatitis C virus recurrence. We identified tendencies towards significant asymmetry for diabetes mellitus (P = 0.06) and hypertension (P = 0.07). This asymmetry may be due to heterogeneity introduced by one study (Belli 1998); when this study was removed, no asymmetry was detected.

DISCUSSION

Summary of main results

We identified 16 completed randomised clinical trials including 1347 participants and one other trial for which limited data were available. Eleven of these completed trials compared glucocorticosteroid avoidance with short-term glucocorticosteroids and the remaining six compared rapid glucocorticosteroid tapers with longer tapers or long-term glucocorticosteroids. All but one trial were two-armed parallel-group trials with one three-armed parallel group trial for which only the control arm and the relevant

intervention arm were included in our review. We aimed to assess mortality, graft loss including death, acute rejection, infection, adverse events, chronic rejection, glucocorticosteroid-resistant rejection, diabetes mellitus, cytomegalovirus (CMV) infection, hepatitis C virus (HCV) recurrence, malignancy, post-transplant lymphoproliferative disorder, renal failure requiring dialysis, renal insufficiency, estimated glomerular filtration rate (eGFR), serum creatinine, de novo autoimmune hepatitis, hypertension, hyperlipidaemia, serum cholesterol, hypercholesterolaemia, and health-related quality of life. Adverse events, renal failure requiring dialysis, eGFR, de novo autoimmune hepatitis, and health-related quality of life were not reported in any of the trials. We assessed all other outcomes in the meta-analysis.

Acute rejection appeared to be increased when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression. Glucocorticosteroid-resistant rejection appeared to be increased when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression. Diabetes mellitus appeared to be increased when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression, when we applied the fixed-effect, but not the random-effects model. Serum creatinine appeared to be increased when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression, when we applied the fixed-effect, but not the random-effects model. Hypertension appeared to be reduced when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression. Serum cholesterol appeared to be reduced when glucocorticosteroid avoidance or withdrawal were compared with glucocorticosteroid-containing immunosuppression.

We found no evidence for an increase or decrease in mortality, graft loss including death, infection, chronic rejection, CMV infection, HCV recurrence, malignancy, post-transplant lymphoproliferative disorder, renal insufficiency, hyperlipidaemia, or hypercholesterolaemia when comparing glucocorticosteroid avoidance or withdrawal with glucocorticosteroid-containing immunosuppression. We performed Trial Sequential Analysis for all outcomes, and for none of the outcomes were the monitoring boundaries crossed or the required information size reached. Hence, we cannot exclude random errors for the results of the conventional meta-analyses.

We identified five trials exclusively composed of or reporting cohorts of hepatitis C virus-infected participants, including 231 participants.

Overall completeness and applicability of evidence

We included 16 completed trials in our meta-analysis, which compared glucocorticosteroid avoidance or withdrawal with glucocorticosteroid-containing immunosuppression. We could not per-

form meta-analyses on each of our predefined outcomes as the trials we identified did not report on all of them. We were unable to include one completed trial due to inadequate data published for this trial.

All of the trials reported on acute rejection. Almost all of the trials reported on mortality, graft loss including death, and diabetes mellitus. Most trials reported on infection, chronic rejection, glucocorticosteroid-resistant rejection, HCV recurrence, and hypertension. Few trials report on CMV infection, malignancy, post-transplant lymphoproliferative disorder, renal insufficiency, serum creatinine, hyperlipidaemia, serum cholesterol, and hypercholesterolaemia. None of the trials reported on adverse events, renal failure requiring dialysis, eGFR, de novo autoimmune hepatitis, or health-related quality of life. Of the outcomes for which few trials reported results, many had conflicting results, as demonstrated by the moderate or significant level of heterogeneity identified in the analyses.

Our meta-analyses include a variety of immunosuppressive regimens including different combinations and types of calcineurin inhibitor, antiproliferative agent, and induction agent and include the majority of the agents in common use. One induction agent in common use, alemtuzumab, was not used in any of the trials. Follow-up in the included trials ranged from six months to 10 years. Our review has very limited evidence for long-term outcomes for glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression. Long-term effects are particularly relevant for mortality, graft loss, malignancy, and post-transplant lymphoproliferative disorder.

The participants included in each of the trials do not fully reflect the characteristics of the general liver transplant population. None of the trials included in our review included paediatric participants and only a limited number included living donors. Only eight of the trials reported on type of donor. There is, however, a variety of concomitant immunosuppressants reflecting the majority of immunosuppressants in current use as well as a variety of indications for transplantation.

Quality of the evidence

The quality of our review findings and interpretations are limited by the number of trials included in the review and the low quality of certain aspects within the trials. For several of the comparisons only a very small number of trials could be included, with limited reporting on the rarer outcomes of interest. These factors are responsible for the broad confidence intervals representing imprecision in many of our analyses.

Our review is limited by indirectness as it does not include paediatric participants or multiple organ transplant recipients. As well as this, many of the included trials listed living donors in their exclusion criteria. For this reason our results cannot be directly related to these patients.

We explored statistical heterogeneity with the Chi^2 test and quantified heterogeneity using the I^2 statistic (Higgins 2002). The Chi^2 test is not as effective for situations where few trials with few participants are included in a meta-analysis, such as is the case for our review. This means that many of the outcomes for which we found a statistically significant difference indicate a moderate or significant level of heterogeneity. It also means that in situations in which a non-statistically significant result was shown, it could still have been influenced by heterogeneity. To overcome this uncertainty, we applied both fixed-effect and random-effects meta-analysis models, and reported both models when we found differences. In our review, the fixed-effect model identified several statistically significant differences, which were not identified by the random-effects model. We considered six outcomes (infection, chronic rejection, diabetes mellitus, malignancy, renal insufficiency, and hypertension) to have moderate levels of heterogeneity. We considered three outcomes (creatinine, cholesterol, and hypercholesterolaemia) to have significant levels of heterogeneity. The outcomes with the highest levels of heterogeneity were reported in only a small number of the included trials. Two of these outcomes were also continuous outcomes and demonstrated considerable inconsistency between the small number of studies in which they were reported. The heterogeneity identified in the outcomes 'Diabetes mellitus' and 'Hypertension' is due to one trial in the glucocorticosteroid withdrawal sub-analysis (Belli 2001). This trial, with over 100 participants, which used rabbit antithymocyte globulin, also used the highest cumulative glucocorticosteroid dose in the glucocorticosteroid-containing group. As glucocorticosteroids are known to increase the rates of hypertension and diabetes mellitus (Hatz 1998), we believe that this comparatively high glucocorticosteroid dose may be responsible for the inconsistency in these outcomes. Following the sensitivity analyses, we found that this trial is also responsible for several of the identified subgroup differences.

We detected possible publication bias for hypertension and diabetes mellitus. This, however, may be due to the heterogeneity introduced by one study and when this study is removed from the analysis, no possibility of publication bias is detected.

Risk of bias is known to be responsible for overestimation of intervention benefits and underestimation of intervention harms in randomised trials with inadequate methodological quality (Schulz 1995; Moher 1998; Kjaergard 2001; Wood 2008; Savović 2012; Savović 2012a; Lundh 2017). Of the 17 included trials, three trials (18%) reported adequate generation of the randomisation sequence, four (24%) reported adequate allocation concealment, three (18%) reported adequate blinding of participants, two (12%) reported adequate blinding of outcome assessors, four (24%) appear to be uninfluenced by incomplete outcome data, 14 (82%) appear to be free from selective reporting, and we could consider none to be free from 'other bias', with reasons being industry sponsorship and lack of reporting of required sample size calculation. Thirteen (76%) appear to be free from early stopping, and 11 (65%) appear to be free from baseline imbalance. We considered all trials to be at high risk of bias.

Potential biases in the review process

We performed a systematic review and meta-analysis in accordance with the methodology described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011).

We followed our peer-reviewed and prepublished protocol with predefined participants, interventions, comparisons, and outcomes to avoid biases in the review preparation (Fairfield 2014). We performed a comprehensive and extensive literature search for both published and unpublished data from a variety of sources that met our predefined inclusion criteria. We extracted all available data and based our meta-analysis on the intention-to-treat principle. We performed several sub-analyses and sensitivity analyses when appropriate to assess the robustness of our data. We performed empirical continuity correction for zero event trials.

Our meta-analysis includes larger numbers of randomised clinical trials on glucocorticosteroid avoidance or withdrawal than other meta-analyses published on this topic (Segev 2008; Sgourakis 2009; Knight 2011; Gu 2014; Lan 2014), improving the quality and comprehensiveness, and reducing the risks of imprecision. Although we contacted various experts in the field and pharmaceutical companies, our search might have missed unpublished data including trials with negative results. This bias remains difficult to avoid. We performed linear regression tests to identify asymmetry in funnel plots in order to identify any possible publication bias. We also contacted the authors of any trials with incomplete data to obtain any unpublished or missing data.

In addition, we conducted Trial Sequential Analyses for all outcomes (Wetterslev 2008; Thorlund 2011b; TSA 2011; Wetterslev 2017) in order to test the robustness of our results. We calculated the DARIS on the basis of type I error of 5%, type II error of 20%, and risk reduction of 20%, and adjusted the information size for diversity (Wetterslev 2009). For all the Trial Sequential Analyses, the cumulative Z-curve did not cross trial sequential monitoring boundaries, and the DARIS was not reached; hence, we cannot exclude random errors regarding our results (play of chance). Except for the outcome HCV recurrence, trial sequential monitoring boundaries were not broken by the cumulative Z-curve, but the required information size of 435 participants was obtained, meaning that we can exclude a relative risk reduction of 20% or more regarding HCV recurrence.

Our search was conducted in May 2017 and it is possible that more recent studies may have been published, which are not considered in our review.

Agreements and disagreements with other studies or reviews

Five non-Cochrane meta-analyses on glucocorticosteroid avoidance or withdrawal for liver transplanted patients have been published (Segev 2008; Sgourakis 2009; Knight 2011; Gu 2014; Lan 2014), as well as one Cochrane network meta-analysis assessing maintenance immunosuppression for liver transplanted patients (Rodríguez-Perálvarez 2017). Three of these meta-analyses also include trials in which glucocorticosteroids have been compared with another agent (Segev 2008; Sgourakis 2009; Gu 2014), but have reported these as sub-analyses allowing for comparisons with our review. One review focuses on comparison of monotherapy with glucocorticosteroid-containing combinations although included studies where monotherapy was compared with three immunosuppressive agents of which one was a glucocorticosteroid (Lan 2014). Our review deals more extensively with risk of bias (systematic errors) and risk of random errors (play of chance) in the randomised clinical trials we identified. We have also performed a much larger number of sub-analyses, and performed Trial Sequential Analyses for all outcomes.

Overall, the meta-analysis in Segev 2008 found a decrease in cholesterol, CMV infection, and HCV recurrence but an increase in acute rejection with glucocorticosteroid avoidance or withdrawal, although no difference in mortality, graft loss, hypertension, diabetes mellitus, glucocorticosteroid-resistant rejection, or infection was observed. Segev 2008 reports statistically significantly decreased rates of acute rejection, glucocorticosteroid-resistant rejection, and diabetes mellitus when glucocorticosteroids are replaced with an alternative immunosuppressive agent. This also means that overall the rates of acute rejection are decreased when these trials are assessed in combination with trials where glucocorticosteroids are not replaced. One possible reason behind the comparatively lower rates of diabetes mellitus when glucocorticosteroids were replaced rather than withdrawn or avoided is that the majority of the trials in the review treated acute rejection with glucocorticosteroids and the higher rates of acute rejection in the trials where glucocorticosteroids were avoided or withdrawn results in glucocorticosteroids being administered for rejection treatment. These pulses of glucocorticosteroids may have increased the rates of diabetes mellitus, masking any benefit gained from not using them (Hatz 1998). This may also explain why Segev 2008 identified statistically significant reductions in HCV recurrence with glucocorticosteroid avoidance or withdrawal whilst our review did not. This is because glucocorticosteroid pulses are known to promote HCV recurrence and the higher rates of acute rejection identified in our review resulted in higher rates of glucocorticosteroid pulses (Sheiner 1995; Singh 1996).

Overall, the meta-analysis in Sgourakis 2009 found a decrease in diabetes mellitus, CMV infection, and cholesterol and an increase in acute rejection with glucocorticosteroid avoidance or withdrawal, although no difference in mortality, graft loss, glucocorticosteroid-resistant rejection, chronic rejection, infection, hypertension, renal insufficiency, and mortality in HCV-infected participants was observed. Sgourakis 2009 also found a decrease in

acute rejection for trials where glucocorticosteroids were replaced by an alternative immunosuppressive agent.

Overall the meta-analysis in Knight 2011 found a decrease in diabetes mellitus and no significant increases or decreases in any other outcomes including mortality, graft loss, hypertension, acute rejection, and cholesterol with glucocorticosteroid avoidance or withdrawal. Knight 2011 contains only seven trials and many of the analyses have significant levels of heterogeneity. A non-significant trend was identified in many of the outcomes, but the low number of trials is likely to have caused wider confidence intervals, preventing genuine effects from being identified.

Overall, the meta-analysis in Gu 2014 found a decrease in diabetes mellitus and CMV infection and no significant increases or decreases in any other outcomes including mortality, graft loss, acute rejection, chronic rejection, HCV recurrence, infection, and hypertension with glucocorticosteroid avoidance or withdrawal.

The meta-analysis in Lan 2014 claims to have found a total of 14 randomised clinical trials assessing immunosuppression monotherapy (using tacrolimus, cyclosporine, or mycophenolate mofetil) versus glucocorticosteroid-containing immunosuppression. A total of seven of the "randomised studies" included in Lan 2014 appear to relate to only three studies (Belli 1998; Moench 2007; Manousou 2009), which have been subject to duplicate publication. The authors of Lan 2014 have included the results of each report as a separate study in each relevant meta-analysis meaning that the same participants have been included multiple times. As a consequence of the probability of duplicate publication bias in the meta-analysis by Lan and colleagues. (Lan 2014), we have therefore decided not to make any comparisons with the results of our review. A letter has been sent to the editor of the relevant journal highlighting the inclusion of duplicate studies in Lan 2014 (Fairfield 2017).

Overall, the network meta-analysis in Rodríguez-Perálvarez 2017 found a reduction in adverse events but no change in mortality or graft rejection with glucocorticosteroid avoidance or withdrawal in cyclosporine-based regimens when making direct comparison. Rodríguez-Perálvarez 2017 found a reduction in adverse events with no change in mortality, graft rejection, or retransplantation with glucocorticosteroid avoidance or withdrawal in cyclosporine-based regimens when making indirect comparison. Overall, the network meta-analysis in Rodríguez-Perálvarez 2017 found an increase in retransplantation but no change in chronic kidney disease with glucocorticosteroid avoidance or withdrawal in tacrolimus-based regimens when making direct comparison. Rodríguez-Perálvarez 2017 found no change in mortality, graft loss, renal impairment, or retransplantation with glucocorticosteroid avoidance or withdrawal in tacrolimus-based monotherapy regimes when making indirect comparison. Rodríguez-Perálvarez 2017 found an increase in retransplantation with glucocorticosteroid avoidance or withdrawal in tacrolimus- and mycophenolate mofetil-based regimens when making indirect comparison. The network meta-analysis in Rodríguez-Perálvarez 2017 includes

only three individual studies assessing glucocorticosteroid avoidance and withdrawal.

In accordance with these meta-analyses, we found statistically significant decreases in diabetes mellitus and cholesterol as well as a statistically significant increase in acute rejection with glucocorticosteroid avoidance or withdrawal when applying conventional meta-analyses. Similar to the other meta-analyses, we found no statistically significant changes in mortality, graft loss, chronic rejection, and infection. We also found a statistically significant increase in glucocorticosteroid-resistant rejection and a statistically significant decrease in hypertension with glucocorticosteroid avoidance or withdrawal.

Reduction in CMV infection, HCV recurrence and adverse events with an increase in retransplantation were not shown in our review. The differences between the findings of our review and those of other published meta-analyses may be due to our review excluding studies comparing glucocorticosteroids with alternative immunosuppressive agents.

A similar meta-analysis has been performed for kidney transplantation (Knight 2010). The review contained 34 trials with a total of 5637 participants and assessed the benefits and harms of glucocorticosteroid avoidance or withdrawal in kidney transplant recipients. Knight 2010 found statistically significant reductions in hypertension (risk ratio (RR) 0.90, 95% confidence interval (CI) 0.85 to 0.94), hypercholesterolaemia (RR 0.76, 95% CI 0.67 to 0.87), diabetes mellitus (RR 0.64, 95% CI 0.50 to 0.83), and creatinine clearance (weighted mean difference (WMD) -3.06 mL/min, 95% CI -4.66 to -1.45), as well as statistically significant increases in acute rejection (RR 1.56, 95% CI 1.31 to 1.87) and creatinine (WMD 4.24 μmol/L, 95% CI 2.08 to 6.40) with glucocorticosteroid avoidance or withdrawal. Knight 2010 observed no statistically significant differences in mortality, graft loss, or glucocorticosteroid-resistant rejection. These findings are very similar to the findings of our review. The differences observed in Knight 2010 in creatinine in kidney transplant recipients were not found in our review for liver transplant recipients; this may be due to the small number of trials included in our review that reported serum creatinine.

Knight 2011 also reports the outcomes with glucocorticosteroid avoidance or withdrawal for heart and pancreas transplantation although only one trial was identified in each. Esmore 1989 reports statistically significant reductions in the number of antihypertensives required (0.8 ± 0.6 antihypertensives versus 1.3 ± 0.7 antihypertensives) and serum cholesterol (5.4 ± 1.2 mmol/L versus 6.2 ± 0.9 mmol/L), as well as statistically significant increases in rejection rates within the first three months from transplantation (2.3 ± 0.23 episodes per 100 patient days versus 1.5 ± 0.18 episodes per 100 patient days) and glucocorticosteroid-resistant rejection (26.4% versus 10.2%) with glucocorticosteroid avoidance or withdrawal for heart transplant recipients. Esmore 1989 reports no statistically significant differences in mortality or graft loss with glucocorticosteroid avoidance or withdrawal. Gruessner

2001 reports a statistically significant reduction in cholesterol and triglyceride levels in simultaneous pancreas and kidney transplant recipients with glucocorticosteroid avoidance or withdrawal (rates not given). Gruessner 2001 reports no statistically significant differences in mortality or graft loss with glucocorticosteroid avoidance or withdrawal.

Possible benefits of glucocorticosteroid avoidance and withdrawal, including reductions in cardiovascular risk factors, were identified in this review. However, possible increases in acute rejection and glucocorticosteroid-resistant rejection were also identified. These findings are similar to reviews of glucocorticosteroid avoidance and withdrawal for heart and kidney transplant recipients. Unfortunately the benefits and harms found in the conventional meta-analysis could not be confirmed by Trial Sequential Analyses meaning that we cannot exclude random errors.

AUTHORS' CONCLUSIONS

Implications for practice

Our review has a low to moderate quality of evidence for the effects of glucocorticosteroid avoidance or withdrawal. The effects of glucocorticosteroid avoidance or withdrawal remain uncertain. Our review showed no clear benefits or harms for mortality, graft loss including death, infection, chronic rejection, cytomegalovirus (CMV) infection, hepatitis C virus (HCV) recurrence, malignancy, post-transplant lymphoproliferative disorder, renal insufficiency, creatinine, hyperlipidaemia, cholesterol, or hypercholesterolaemia. Hypertension and diabetes mellitus may be reduced, but acute rejection and glucocorticosteroid-resistant rejection may be increased with glucocorticosteroid avoidance or withdrawal. Glucocorticosteroid-free immunosuppression may provide a safe alternative for liver transplanted patients who are intolerant of glucocorticosteroids. Although we found no statistically significant difference for mortality or graft loss, these findings should be interpreted with caution.

Implications for research

Given the results of our analysis, it appears that appropriately sized randomised clinical trials comparing glucocorticosteroid avoidance or withdrawal with glucocorticosteroid-containing immunosuppression in liver transplant participants using contemporarily adjunctive immunosuppression are warranted. As episodes of acute rejection following liver transplantation tend to occur more frequently in the initial weeks following transplantation (Wiesner 1998), trials investigating whether short-term glucocorticosteroids (first few weeks) reduce the rates of acute rejection without exposing liver transplant recipients to cardiovascular risk factors for long periods of time appear to be warranted. We feel it may be of benefit to construct a high-quality three-arm trial comparing

complete postoperative glucocorticosteroid avoidance, short-term glucocorticosteroids, and long-term glucocorticosteroids.

Our review did not identify any statistically significant increase or decrease in HCV recurrence with glucocorticosteroid-free immunosuppression despite reports that glucocorticosteroids increase the severity of HCV hepatitis (Sheiner 1995; Singh 1996; Segev 2008; Sgourakis 2009). One possible reason for this is the higher rate of acute rejection in the glucocorticosteroid-free arm, which was treated with glucocorticosteroid pulses. It is possible that with the use of alternative immunosuppression strategies to prevent rejection that glucocorticosteroid-free immunosuppression may lead to lower rates of HCV recurrence (Hibi 2015). Our review identified a number of studies published between 2009 and 2017 in which glucocorticosteroids were replaced with an alternative immunosuppressant. An updated systematic review and meta-analysis of these studies is merited.

These trials should be conducted with low risk of systematic error (bias) and low risk of random error (play of chance), and should follow the 'SPIRIT' guidelines (SPIRIT 2013a; SPIRIT 2013b) and 'CONSORT' guidelines (www.consort-statement.org).

CHARACTERISTICS OF STUDIES

Characteristics of included studies *[ordered by study ID]*

Belli 1998

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: total: 41 ± 16 months, range 4 to 68 months Study duration: date of randomisation to last follow-up before 28 February 1997, or patient death or re-transplantation Language: English Type of information: journal article Judgement on quality: unclear risk of bias
Participants	Setting: Ospedale Niguarda Ca' Granda, Milan, Italy Allocation of participants: 104 participants, 50 allocated to long-term glucocorticosteroids, 54 allocated to short-term glucocorticosteroids Sex ratio: total: 74 (71%) males, 30 (29%) females Intervention A: 37 (74%) males, 13 (26%) females Intervention B: 37 (68.5%) males, 17 (31.5%) females Mean age: total: not reported Intervention A: 45 ± 14 Intervention B: 42 ± 16 Indication (no. (%)): (indications reported for whole study population but not intervention groups) HCV: 42 (40.4%) HBV: 24 (23.1%) HBV and HCV: 8 (7.7%) Alcoholic cirrhosis: 9 (8.7%) Primary biliary cirrhosis: 6 (5.8%) Cryptogenic cirrhosis: 8 (7.7%) Others: 7 (6.7%) Type of donor: not reported Inclusion criteria: adult liver transplant recipients Exclusion criteria: previous liver transplant, previous other organ transplant, multiorgan transplant Other: rejection before randomisation (n (%)): Intervention A: 15 (30%) Intervention B: 22 (41%)
Interventions	Intervention A: methylprednisolone: from day 90, 20 mg per day with 5 mg reductions every 2 weeks until stopped Intervention B: methylprednisolone: from day 90, 20 mg per day with 5 mg reductions every 2 weeks until maintenance dose of 0.1 mg/kg/day continued for duration of study Concomitant immunosuppression: Rabbit antithymocyte globulins: 2 mg/kg/day for 5 to 7 days from day 0 Cyclosporine A: 200 to 300 ng/mL (from day 90 for "first months") and 150 ng/mL to 250 ng/mL thereafter Methylprednisolone: 1000 mg intraoperatively; 200 mg at day 1; 160 mg at day 2; 120 mg at day 3; 80 mg at day 4; 40 mg at day 5; 20 mg at day 6; then continued at the

	same dose until day 90
Outcomes	Patient survival, acute rejection, chronic rejection, hypertension, diabetes, severe bone complications, infections, serum cholesterol, recurrent hepatitis B, recurrent hepatitis C and treatment failure
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from the publication: "One hundred four first orthotopic liver transplantations performed between May 1991 and June 1995 at the Niguarda Hospital in Milan and surviving long enough to reach the randomization time point were prospectively assigned to one of the two maintenance immunosuppressive regimens. Fifty patients were randomized to receive cyclosporine plus long-term corticosteroids (Group I) and 54 patients were randomized to cyclosporine monotherapy (Group II)." Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All predefined outcomes and clinically relevant outcomes appear to be reported
Other bias	Unclear risk	Comment: No sample size calculation reported

Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Comment: No evidence of baseline imbalance reported in "Table 3"

Belli 2001

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: not reported Intervention A: 22 months Intervention B: 21 months Study duration: randomisation from November 1997 to November 1999, duration from randomisation not reported Language: English Type of information: journal article Judgement on quality: high risk of bias
Participants	Setting: Ospedale Niguarda Ca' Granda, Milan, Italy Allocation of participants: 24 participants, 13 allocated to glucocorticosteroids, 11 allocated to no intervention Sex ratio: total: not reported Intervention A: not reported Intervention B: not reported Mean age: total: not reported Intervention A: not reported Intervention B: not reported Indication (no. (%)): HCV cirrhosis: total: 24 (100%), Intervention A: 13 (100%), Intervention B: 11 (100%) Type of donor: not reported Inclusion criteria: adult liver transplant recipients with HCV cirrhosis Exclusion criteria: not reported
Interventions	Intervention A: no intervention Intervention B: glucocorticosteroids for 3 months, doses not reported Concomitant immunosuppression: Rabbit antithymocyte globulin: dose not reported, given for 5 days Azathioprine: dose not reported, given for 1 month Cyclosporine A: dose not reported
Outcomes	Acute rejection, chronic rejection, recurrent hepatitis C, severe cholestasis, ALT, mortality, portal vein thrombosis
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: not reported One intervention group was excluded from the meta-analysis as differences between hepatitis C virus prophylaxis (ribavirin) were noted Although the overall data for mortality and portal vein thrombosis have been reported,

the exact number of participants in each group with these outcomes is not reported, therefore these results are not included in the meta-analysis but are included in the best-worst worst-best analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from the publication: "Between November 1997 and November 1999 37 patients (pts) were randomized to one of three groups: ..." Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment:Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	High risk	Quote from the publication: "Of these 37 pts, only 30 were considered in the analysis. Seven pts were excluded because of early death after transplant (6 pts) or because of concurrent confounding clinical problems (1 pt with portal vein thrombosis)." Comment: Mortality and portal vein thrombosis not reported fully. As this is a three-arm trial it is not possible to accurately record data on mortality within each group as the trial does not report which arm of the trial the portal vein thrombosis occurred in and which arms of the trial each mortality occurred in. Therefore, the outcomes have not been included in the meta-analysis but have been included in the best-worst worst-best analyses. Otherwise, number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported

Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Unclear risk	Comment: Baseline characteristics not reported

Chen 2007

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: not reported Intervention A: not reported Intervention B: not reported Study duration: not reported Language: English Type of information: journal article Judgement on quality: unclear risk of bias
Participants	Setting: Tongji Hospital, Wuha, Hubei Province, China Allocation of participants: 54 participants, 28 allocated to Intervention A, 26 allocated to Intervention B Sex ratio: total: 53 (98%) males, 1 (2%) female Intervention A: 27 (96%) males, 1 (4%) female Intervention B: 26 (100%) males, 0 (0%) female Mean age: total: not reported Intervention A: 45.7 ± 3.5 Intervention B: 47.4 ± 6.3 Indication (no. (%)): Hepatocellular carcinoma: total: 54 (100%), Intervention A: 28 (100%), Intervention B: 26 (100%) Type of donor: not reported Inclusion criteria: not reported Exclusion criteria: not reported Other: Cold ischaemia time (minutes): total: not reported, Intervention A: 486.1 ± 97.0, Intervention B: 462.1 ± 88.0 Warm ischaemia time (minutes): total: not reported. Intervention A: 51.5 ± 3.4, Intervention B: 50.8 ± 3.1
Interventions	Intervention A: glucocorticosteroids: 3 months rapid taper to stop at 3 months, type of glucocorticosteroid and doses not reported Intervention B: glucocorticosteroids: 3 months slow taper with 10 mg/day maintenance long-term, type of glucocorticosteroid and doses during taper not reported Concomitant immunosuppression: Methylprednisolone: 500 mg/day for 3 days Tacrolimus: aiming for trough doses of 6 to 8 micrograms/mL for 1 year and then 4 to 6 micrograms/mL thereafter

	Mycophenolate mofetil: 0.5 to 1 g/day for 1 year and then stopped at 1 year
Outcomes	Mortality, acute rejection, creatinine, HCC recurrence, ALT, cholesterol, fasting blood sugar
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote from the publication: "Fifty-four patients suffering from advanced-stage hepatoma (all exceeding the Milan criterion) underwent liver transplantation between April 2003 and June 2005. There were two immunosuppressive protocols: 28 patients (group A) were given an early steroid-withdrawal protocol and 26 patients (group B) were given a steroid-maintenance protocol." Quote from the publication: "This randomized clinical study was focused on a particular group of recipients who suffered from advanced-stage hepatocellular carcinoma before liver transplantation." Quote from the "Comments" section of the publication: "The present study was a randomized clinical trial of steroid withdrawal after liver transplantation in patients with advanced-stage hepatocellular carcinoma. We have cited several articles from other investigators that report research on steroid withdrawal after liver transplantation." Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described

Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Unclear risk	Comment: Study does not appear to be stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "Factors such as age at transplantation, stage of carcinoma, Child-Pugh score, graft cold ischemic time, anhepatic phase, operation time, and mean level of liver function before operation were noted, and these parameters were well matched in both groups (Table 1)." Comment: Study appears to be free from baseline imbalance

Hu 2008

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: not reported Study duration: 6 months from randomisation, randomisation from September 2006 to March 2008 Language: Mandarin Type of information: journal article Judgement on quality: unclear risk of bias
Participants	Setting: Organ Transplantation Center, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China Allocation of participants: 76 participants, 36 allocated to Intervention A, 40 allocated to Intervention B Sex ratio: total: not reported Intervention A: 5:1 (numbers and % not reported) Intervention B: 4:1 (numbers and % not reported) Mean age: total: not reported Intervention A: 47.6+/-5.8 Intervention B: 45.2+/-6.5 Indication (no. (%)): not reported Type of donor: deceased donor Inclusion criteria: first liver transplantation, hepatocellular carcinoma, aged 18 to 65, deceased donor transplantation and informed consent given Exclusion criteria: previous liver transplant, multi-organ transplantation, living donor

	transplantation, ABO-incompatible transplantation. Primary disease: primary sclerosing cholangitis or autoimmune hepatitis. Preoperative psychiatric symptoms, gastric ulcer, use of hormones, diabetes mellitus, hypertension, hyperlipidaemia or malignancy other than primary hepatocellular carcinoma. Participation in other trials
Interventions	Intervention A: no intervention Intervention B: prednisone from day 8, commencing at 48 mg reduced by 8 mg every 3 days to a maintenance dose of 4 mg by day 26, stopped after 3 months Concomitant immunosuppression: Tacrolimus: 3 mg intraoperatively then adjusted postoperatively to 8 to 12 micrograms/mL Methylprednisolone: 1000 mg intraoperatively, then 500 mg on day 1, 240 mg on day 2, 200 mg on day 3, 160 mg on day 4, 80 mg on day 5, 40 mg on day 6 and 20 mg on day 7
Outcomes	Mortality, infection, hepatic artery thrombosis, hypertension, diabetes mellitus, hyperlipidaemia, neurotoxicity, gastrointestinal complications, other adverse events
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: National Nature foundation, China Medical Board in New York, Nature foundation of Guangzhou province

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	Unclear risk	Comment: No sample size calculation reported

Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Comment: Study appears to be free from baseline imbalance

Ju 2012

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: total: not reported; Intervention A: 23 months (range: 12 to 36 months); Intervention B: 21 months (range: 12 to 36 months) Study duration: 3 years from randomisation, randomisation from September 2006 to September 2008 Language: English Type of information: journal article Judgement on quality: unclear risk of bias
Participants	Setting: Organ Transplantation Center, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China Allocation of participants: 87 participants, 44 allocated to Intervention A, 43 allocated to Intervention B Sex ratio: total: 64 (78.0%) males, 18 (22.0%) females Intervention A: not reported Intervention B: not reported Mean age: total: 45.7 (range: 26 to 68) Intervention A: not reported Intervention B: not reported Indication (no. (%)): (indications reported for whole study population but not intervention groups) Hepatocellular carcinoma: total: 36 (43.9%) HBV cirrhosis: total: 33 (40.2%) HCV cirrhosis: total: 3 (3.7%) Alcoholic cirrhosis: total: 3 (3.7%) Severe hepatitis: total: 6 (7.3%) Polycystic liver: total: 1 (1.2%) Type of donor: deceased donor Inclusion criteria: adult liver transplant recipients Exclusion criteria: pretransplant infection (except HBV, HCV), marginal grafts (donors with moderate to severe NAFLD, HBV infection, age > 60, cold ischaemia > 14 hours), multiorgan transplants, retransplant, partial liver transplant including living donor, lack of consent, ABO incompatibility
Interventions	Intervention A: no intervention Intervention B: methylprednisolone at 240 mg on day 1 tapered by 10 mg/day for 8 days. Prednisone at 48 mg on day 9 with 8 mg tapered until 4 mg/day by day 26 before stopping at 3 months Concomitant immunosuppression: Methylprednisolone: 500 mg intraoperatively Basiliximab: 20 mg perioperatively

	Tacrolimus: commenced on day 4 at 0.04 mg/kg/day aiming for trough levels of 8 to 12 ng/mL, tapered to 6 to 10 ng/mL by 3 months and 5 to 8 ng/mL by 6 months Mycophenolate mofetil: as required Sirolimus: as required	
Outcomes	Mortality, acute rejection, CMV infection, hypertension, hyperlipidaemia, hyperglycaemia, infection	
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: National High Technology Research and Development Program of China, the Key Clinical Project from the Ministry of Health, National Natural Science Foundation of China, special fund for science research by Ministry of Health, the China Medical Board in New York, the Key Projects in the National Science & Technology Pillar Program during the Eleventh Five-Year Plan Period of China and Science and Technology Planning Project of Guangdong Province	

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from the publication: "After screening, 91 patients were randomized to receive standard immunosuppressive protocol (SP group) or 24-hour steroid avoidance protocol (24-h SA group) according to random sequence generated by SPSS software (SPSS: An IBM Company, version 13. 0, IBM Corporation, Armonk, New York, USA)." Comment: Randomisation achieve by computer-generated random sequence
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	Unclear risk	Quote from the publication: "Nine patients were excluded from the analysis owing to ABO blood type incompatibility (4/9) and perioperative death (5/9). Among the patients who died perioperatively, 3 pa-

		tients in the SP group died of acute heart failure (1/5), renal failure (1/5), and massive intraperitoneal bleeding (1/5), and 2 patients in the 24-h SA group died of renal failure (1/5) and primary allograft non-function (1/5)." Comment: The publication provides sufficient information to allow participants excluded due to perioperative mortality to be re-entered into the meta-analysis. Otherwise, the number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Unclear risk	Quote from the publication: "There was no significant difference between the groups when comparing the number of cases and duration of MMF or sirolimus use postoperatively (Table 1)." Comment: The publication reports that there is no significant difference between mycophenolate mofetil or sirolimus use between the groups both other baseline characteristics are not reported

Lerut 2008

Methods	Trial design: randomised, double-blinded, placebo-controlled, single-centre clinical trial Mean follow-up: total: 48 months (range: 12 to 84 months) Study duration: 5 years from randomisation Language: English Type of information: journal article Judgement on quality: high risk of bias
Participants	Setting: Université Catholique de Louvain Cliniques, Universitaires Saint-Luc, Brussels, Belgium Allocation of participants: 156 participants, 78 allocated to Intervention A, 78 allocated to Intervention B Sex ratio: total: 98 (62.8%) males, 58 (37.2%) females Intervention A: 50 (64.1%) males, 28 (35.9%) females Intervention B: 48 (61.5%) males, 30 (38.5%) females

	Mean age: total: not reported Intervention A: 52.1 ± 13.0 Intervention B: 49.0 ± 12.7 Indication (no. (%)): HCV cirrhosis: total: 35 (22.4%), Intervention A: 21 (26.9%), Intervention B: 14 (17.9%) Cholestatic disease: total: 18 (11.5%), Intervention A: 10 (12.8%), Intervention B: 8 (10.3%) Vascular disease: total: 3 (1.9%), Intervention A: 3 (3.8%), Intervention B: 0 (0%) Metabolic disease: total: 9 (5.8%), Intervention A: 2 (2.6%), Intervention B: 7 (9.0%) Benign tumour: total: 9 (5.8%), Intervention A: 4 (5.1%), Intervention B: 5 (6.4%) Hepatocellular carcinoma: total: 37 (23.7%), Intervention A: 19 (24.4%), Intervention B: 18 (23.1%) Fulminant failure: total: 22 (14.1%), Intervention A: 9 (11.5%), Intervention B: 13 (16.7%) Type of donor: living and deceased donors Inclusion criteria: adult liver transplant recipient Exclusion criteria: unfavourable oncological diagnosis, already included in another RCT Other: Ischaemia time: Intervention A: 603+/-231 minutes, Intervention B: 682+/-204 minutes Artificial organ support: total: 11 (7.1%), Intervention A: 10 (12.8%), Intervention B: 1 (1.3%) Right liver living liver transplantation: total: 9 (5.8%), Intervention A: 0 (0%), Intervention B: 9 (11.5%) Baseline imbalance: the intervention groups differ significantly in relation to ischaemia time, living donor liver transplantation and artificial organ support
Interventions	Intervention A: matched placebo Intervention B: methylprednisolone started at 16 mg then tapered every 14 days by 4 mg from day 21 to stop at day 64 Concomitant immunosuppression: Tacrolimus: aiming for trough level of 5 to 8 ng/mL Hydrocortisone: 1000 mg intraoperatively
Outcomes	Mortality, graft loss, acute rejection, glucocorticosteroid-resistant rejection, chronic rejection, infection, bacterial infection, viral infection, fungal infection, CMV infection, bilirubin, ALT, GGT, post-transplant lymphoproliferative disorder (PTLD), renal insufficiency, diabetes mellitus, new-onset diabetes after transplantation (NODAT), hyperuricaemia, hypercholesterolaemia, hypertension, de novo hypertension, osseo-muscular pain or fractures, cataract, Karnofsky index, recurrent hepatitis C, intrahepatic biliary problems
Notes	Cross-over between intervention arms: no Sample size calculation: yes Sources of funding: the Belgian FRSM, Astellas Pharma, Munchen, Germany

Risk of bias

Bias	Authors' judgement	Support for judgement

Random sequence generation (selection bias)	Unclear risk	Quote from the publication: "The patients were randomized, 1:1 into our previously used IS scheme consisting of TAC-low dose and short-term steroids (TAC-ST; n 78) or into TAC-placebo (TAC-PL; n 78)." Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Low risk	Quote from the publication: "The randomization was done at the end of surgery using serially numbered, sealed, and opaque envelopes." Comment: Adequate allocation concealment using sealed, opaque envelopes
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote from the publication: "Steroids and placebos were administered in identical plastic containers containing a similar number of identical, opaque capsules. Their number, corresponding to a reducing dose that covered a post-LT period of 64 days, was prepared by an independent pharmacist." Quote from the publication: "All patients, health care providers, and outcome assessor teams were blinded until the 12-month analysis was complete." Comment: Double-blinded trial, both participants and medical staff blinded to treatment. Adequate placebo using identical opaque capsules
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote from the publication: "All patients, health care providers, and outcome assessor teams were blinded until the 12-month analysis was complete." Comment: All outcome assessors including pathologists blinded
Incomplete outcome data (attrition bias)	Low risk	Quote from the publication: "There were no dropouts or withdrawals in either intervention group." Quote from the 2014 publication: "Five-year biopsy was done in 112 (89.6%) patients (Table 2). Twelve (9.6%) patients with stable, normal liver tests refused a biopsy (n = 11); once (0.8%) tissue material was insufficient for analysis."

Lerut 2008 (*Continued*)

		No missing outcome data, no withdrawals. Data missing from participants refusing liver biopsy in the five-year follow-up unlikely to affect outcome results
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "This work was supported by a grant from the Belgian FRSM (3.4548.02). Astellas Pharma, Munchen, Germany provided the randomization envelopes and an unrestricted grant, which will be used to cover pharmacodynamic and viral (HCV) monitoring, which are not included in this report." Comment: Study is industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	High risk	Quote from the publication: "Technical variants were not taken into account when randomizing the patients because in our center, results of elective living LT and split LT are similar to those obtained after whole LT. The need for artificial organ support also was not considered for randomization, as the placebo group would have a lower degree of IS anyway. The randomization was also independent of the presence of positive lymphocytotoxic cross-match and of viral HBV or HCV infection. The characteristics of the study population are summarized in Table 1. The groups differed significantly in relation to total ischemia time, frequency of living donor LT, need for artificial (renal, hepatic, and pulmonary) organ support, and mean creatinine values during the first 14 post-LT days." Comment: Study not free from baseline imbalance

Llado 2006

Methods	Trial design: randomised, multicentre, open-label clinical trial
	Mean follow-up: not reported
	Study duration: randomisation between April 2001 and September 2004, 6 months
	from randomisation (longer for HCV-positive patients)
	Language: English
	Type of information: journal article
	Judgement on quality: high risk
Participants	Setting: 7 transplantation centres in Spain
	Allocation of participants: 198 participants, 102 allocated to Intervention A, 96 allocated
	to Intervention B
	Sex ratio: total: 155 (78.3%) males, 43 (21.7%) females
	Intervention A: 80 (78.4%) males, 22 (21.6%) females
	Intervention B: 75 (78.1%) males, 21 (21.9%) females
	Mean age: total: not reported
	Intervention A: 55.4 ± 8.9
	Intervention B: 52.9 ± 9.5
	Indication (no. (%)):
	HCC: total: 63 (31.8%), Intervention A: 34 (33.3%), Intervention B: 29 (30.2%)
	HCV cirrhosis: total: 46 (23.2%), Intervention A: 20 (19.6%), Intervention B: 26 (27.1%)
	HBV cirrhosis: total: 14 (7.1%), Intervention A: 8 (7.8%), Intervention B: 6 (6.3%)
	Alcoholic cirrhosis: total: 55 (27.8%), Intervention A: 29 (28.4%), Intervention B: 26 (27.1%)
	Other: total: 20 (10.1%), Intervention A: 11 (10.8%), Intervention B: 9 (9.4%)
	Type of donor: deceased donor
	Inclusion criteria: liver transplant recipients from cadaveric donors aged > 18
	Exclusion criteria: exclusion criteria: transplant for fulminant liver disease, retransplant,
	previous or concurrent other organ transplant, autoimmune hepatitis, primary biliary
	cirrhosis, HIV infection, likely poor compliance
	Other:
	Disease status:
	HCV-positive recipient: total: 88 (44.4%), Intervention A: 45 (44.1%), Intervention B:
	43 (44.8%)
	CMV-positive recipient: total: 165 (83.3%), Intervention A: 83 (81.3%), Intervention
	B: 82 (85.4%)
	Diabetes mellitus pretransplant: total: 49 (24.7%), Intervention A: 28 (27.5%), Inter-
	vention B: 21 (21.9%)
	Glycated haemoglobin pretransplant: total: not reported, Intervention A: 4.9 ± 1.5,
	Intervention B: 4.6 ± 0.9
	Hypertension pretransplant: total: 17 (8.6%), Intervention A: 11 (10.8%), Intervention
	B: 6 (6.3%)
	Serum cholesterol pretransplant: total: not reported, Intervention A: 3.8 ± 1.2, Inter-
	vention B: 4.0 ± 1.3 (%)
Interventions	Intervention A: no intervention
	Intervention B: hydrocortisone: 500 mg intraoperatively, then 0.5 mg/kg/day for days 1
	to 5, 0.25 mg/kg/day for days 6 to 30, 0.15 mg/kg/day for days 31 to 90, no intervention
	from day 91
	Concomitant immunosuppression:

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients (Review) 59

Copyright © 2018 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

	Basiliximab: 20 mg intraoperatively Cyclosporine A: started at 10 mg/kg/day aiming for trough levels of 800 ng/mL to 1200 ng/mL
Outcomes	Mortality, graft loss, acute rejection, glucocorticosteroid-resistant rejection, chronic rejection, adverse events, infections, bacterial infection, viral infection, fungal infection, CMV infection, HSV infection, metabolic decompensations, diabetes mellitus, hypertension, recurrent hepatitis C, treatment failure, renal failure, neurological deficit, gingival hypertrophy, de novo malignancy, cholesterol, triglyceride, days until rejection
Notes	Cross-over between intervention arms: no Sample size calculation: yes Sources of funding: Novartis Pharma, TV3 Marathon Foundation

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "The trial was an open-label, not-blinded, prospective, randomized study." Comment: Blinding of participants and medical staff not performed
Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "The trial was an open-label, not-blinded, prospective, randomized study." Comment: Blinding of outcome assessors not performed
Incomplete outcome data (attrition bias)	Unclear risk	Quote from the publication: "Two patients were exclude from the study after randomization because of protocol violations." Comment: The protocol violations are not described and the groups to which these patients were randomised is not described. Otherwise, the number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported

Llado 2006 *(Continued)*

Other bias	High risk	Quote from the publication: "The authors who have taken part in this study have declared a relationship with the manufacturers of the drugs involved and they received funding from the drug companies involved to carry out their research." Quote from the publication: "We are grateful to Infociencia Clinical Research for monitoring the study, and especially thank Cati Bonet for the statistical analysis. This research was supported by Novartis Pharma, and by the TV3 Marathon Foundation." Comment: Study is partly industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "Patient demographics and baseline characteristics were similar between groups (Table 1). It should be noted that 45% of patients were HCV-positive. Main operative and initial post-operative evolution was also similar between groups (Table 2)" Comment: Study free from baseline imbalance

Margarit 2005

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: 44 months (range: 3 to 60) Study duration: randomisation from October 1998 to September 2000, 5 years from randomisation Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: Liver Transplantation Unit, Hospital General Vall Hebron, Barcelona, Spain Allocation of participants: 63 participants, 33 allocated to Intervention A, 30 allocated to Intervention B Sex ratio: total: 43 (71.7%) males, 17 (28.3%) females Intervention A: 25 (78.1%) males, 7 (21.9%) females Intervention B: 18 (64.3%) males, 10 (35.7%) females Mean age: total: not reported Intervention A: 56 ± 8 Intervention B: 57 ± 7 Indication (no. (%)):

	HCV cirrhosis: total: 35 (58.3%), Intervention A: 15 (46.9%), Intervention B: 20 (71.4%)
	Alcoholic cirrhosis: total: 16 (26.7%), Intervention A: 11 (34.4%), Intervention B: 5 (17.9%)

	Concomitant immunosuppression:
	Tacrolimus: 0.05 mg/kg twice daily aiming for trough levels of 10 to 15 ng/mL for "a few weeks" and 8 to 12 ng/mL thereafter
Outcomes	Mortality, infection, bacterial infection, viral infection, fungal infection, toxicity, HCV recurrence, severity of recurrent hepatitis C, renal insufficiency, de novo hypertension, de novo diabetes mellitus, dyslipidaemia, neurological complications, diarrhoea
Notes	Cross-over between intervention arms: no
	Sample size calculation: not reported
	Sources of funding: Fujisawa GM

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Low risk	Quote from email correspondence with author (Bilbao, I) in response to the question "How was the randomisations sequence generated?": "68 closed envelopes numbered 1 to 68 respectively, were prepared before starting the trial. The envelopes were opened consequently when the surgery started." Comment: Sealed, opaque envelopes
Blinding of participants and personnel (performance bias) All outcomes	High risk	Comment: Blinding of participants and medical staff not performed

Margarit 2005 *(Continued)*

Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from email correspondence with author (Bilbao, I) in response to question "Were the outcome assessors blinded to the patient's treatment?": "NO" Quote from email correspondence with author (Bilbao, I) in response to question "Were the pathologists confirming rejection blinded to the patient's treatment?": "YES" Comment: Blinding of pathologists performed; blinding of all other outcome assessors not performed
Incomplete outcome data (attrition bias)	Unclear risk	Quote from the publication: "Three patients were excluded after randomization because of perioperative death (n = 2) and positive cross-match (n = 1)." Quote from email correspondence with author (Bilbao, I) in response to question "Of the three patients who died after randomization, had any of the patients begun treatment? If this is the case which group were the two deaths part of and which was the patient with the positive cross-match part of?": "One death belonged to Tacro group and the other to the Tacro + Prednisone. The patient with positive crossmatch belonged to Tacro group. The death in Tacro group did not begin treatment because intraoperative problems and at the end of the surgery received standard immunosuppression at that time (Tacro + steroids). The one in Tacro + steroids died at 3 rd day postop and began treatment. The patient with positive crossmatch began treatment for 36 hours, but then was changed to standard triple therapy" Comment: Three participants removed from analysis following randomisation following data-dependent processes not described in exclusion criteria. It was possible to incorporate some of the data on mortality from these participants based on email correspondence with the author. Otherwise, the number of withdrawals and reasons for withdrawal were not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to have been reported

Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	High risk	Quote from the publication: "No differences were found between treatment groups except for a higher incidence of graft steatosis in TACRO + ST and of HCV-positive patients in the TACRO group. Primary graft dysfunction secondary to ischaemic-reperfusion injury that could affect tacrolimus metabolism and pharmacokinetic parameters was similar in both groups." Comment: Baseline imbalance observed in recipient HCV cirrhosis and donor graft steatosis

Moench 2007

Methods	Trial design: randomised, double-blinded, placebo-controlled, single-centre clinical trial Mean follow-up: not reported as all patients followed up at 5 years, except deaths Study duration: 5 years from randomisation, randomisation from February 2000 to July 2004 Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: Johannes Gutenberg University Mainz Hospital, Langenbeckstrasse 1, Mainz, Germany Allocation of participants: 110 participants, 54 allocated to Intervention A, 56 allocated to Intervention B Sex ratio: total: 74 (67.3%) males, 36 (32.7%) females Intervention A: 36 (66.7%) males, 18 (33.3%) females Intervention B: 38 (67.9%) males, 18 (32.1%) females Mean age: total: not reported Intervention A: 53.5 ± 8.3 Intervention B: 53.6 ± 10.4 Indication (no. (%)): Hepatocellular carcinoma: total: 40 (36.4%), Intervention A: 19 (35.2%), Intervention B: 21 (37.5%) HBV cirrhosis: total: 19 (17.3%), Intervention A: 7 (13.0%), Intervention B: 12 (21.4%) HCV cirrhosis: total: 31 (28.2%), Intervention A: 15 (27.8%), Intervention B: 16 (28.6%) Alcoholic cirrhosis: total: 37 (33.6%), Intervention A: 21 (38.9%), Intervention B: 16 (28.6%)

	Primary biliary cirrhosis or primary sclerosing cholangitis: total: 8 (7.3%), Intervention A: 5 (9.3%), Intervention B: 3 (5.4%) Type of donor: deceased donor after brain death (DBD) or living-related donor Inclusion criteria: orthotopic liver transplant recipients aged > 18 receiving transplant for any indication, recipients of whole or partial liver grafts from brain dead donors as well as living-related donors, oral informed consent Exclusion criteria: previous organ transplants including liver retransplantation; initial, sequential or parallel therapy with other immunosuppressive drugs besides the study protocol; corticosteroid therapy within 6 months before transplantation; HIV infection; pregnancy and breast feeding; allergy to or intolerance of study medication; participation in another clinical study Other: Partial graft: total: 6 (5.5%), Intervention A: 3 (5.6%), Intervention B: 3 (5.4%) Deceased donor: total: 100 (90.9%), Intervention A: 50 (92.6%), Intervention B: 50 (89.3%) Living donor: total: 10 (9.1%), Intervention A: 4 (7.4%), Intervention B: 6 (10.7%)
Interventions	Intervention A: matched placebo Intervention B: methylprednisolone: 12 mg/day from day 15 to 60, 8 mg/day from day 61 to 180 then tapered to stop over 2 weeks Concomitant immunosuppression: Tacrolimus: initial dose of 0.01 mg/kg/day with target trough levels 10 to 15 ng/mL for days 0 to 42 and 5 ng/mL to 10 ng/mL thereafter Methylprednisolone: 1000 mg before reperfusion, 100 mg on day 1, 75 mg on day 2, 48 mg on day 3 and 4, 36 mg on day 5 and 6, 24 mg on day 7 and 8, 16 mg on days 9 to 13 and 12 mg on day 14
Outcomes	Mortality, graft loss, acute rejection, time to first rejection, severity of rejection, recurrent acute rejection, glucocorticosteroid-resistant rejection, chronic rejection, hypertension, diabetes mellitus, infection, CMV infection, post-transplant lymphoproliferative disorder, hypercholesterolaemia, hypertriglyceridaemia, osteoporosis, cholesterol, triglyceride, creatinine, HDL cholesterol, LDL cholesterol, fasting blood glucose, neurological toxicity, abnormal liver function, abnormal renal function
Notes	Cross-over between intervention arms: no Sample size calculation: yes Sources of funding: Astellas Pharma Munich, Germany

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Low risk	Quote from the publication: "Patient care and study conduct complied with good clinical practice.1:1 randomization was performed by a blinded randomization list

		generated by the Biomathematical Institute prior to transplantation in eligible patients (Figure 1)." Comment: Allocation concealment not fully described, however, the publication describes the randomisation sequence as "blinded" in addition to the blinding or participants and outcome assessors described elsewhere
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote from the publication: "This was a 12-month, prospective, randomized, double-blinded, placebo-controlled investigator driven, monocenter trial comparing early FK506 monotherapy with FK506 plus steroids." Quote from the publication: "After day 14, patients received study medication, either placebo or methylprednisolon capsules in a double-blinded way. Study medication was manufactured, packed and blinded by the Pharmacy Department of Johannes Gutenberg University Hospital." Quote from the publication: " Patients who experienced three or more episodes of acute rejection during the follow-up were excluded from the trial, unblinded and received individualized immunosuppressive therapy Comment: Double-blinded trial, both participants and medical staff blinded to treatment
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of pathologists not described
Incomplete outcome data (attrition bias)	Low risk	Quote from the publication: "The number of patients completing the follow-up were 35 (66.7%) in the steroid group and 36 (62. 5%) in the placebo group (p = 0.801, chi-square). Reasons for withdrawal from the trial were death (n = 14, 12.7%), recurrent rejection (n = 11, 10.0%), severe adverse events (n = 10, 9.1%) and secondary refusal to informed consent (n = 1, 0.9%)." Quote from the publication: "Fourteen (12.7%) patients died during follow-up, 6 (11.1%) in the steroid group and 8 (14.

Moench 2007 (*Continued*)

		3%) in the placebo group (p = 0.617, chisquare). At month 6, 46 patients were still in the steroid and the placebo group. Eight patients were withdrawn from the steroid group and 10 patients were withdrawn from the placebo group during the first 6 months. At month 12, 35 patients were still in the steroid group and 36 patients were still in the placebo group. Eleven patients were withdrawn from the steroid group and 10 patients were withdrawn from the placebo group during month 6 until month 12." Comment: The numbers and reasons for dropouts are adequately described
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "The study was supported by Astellas Pharma Munich, Germany." Comment: Study is industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "Patientsdemographicsandbaselinecharacteristics were comparable in both groups and are demonstrated in Table 1." Comment: Study free from baseline imbalance

Pageaux 2004

Methods	Trial design: randomised, multicentre, double-blinded, placebo-controlled clinical trial Mean follow-up: not reported Study duration: 1 year from randomisation, randomisation from December 1999 to August 2001 Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: 7 transplantation centres in France Allocation of participants: 174 participants, 90 allocated to Intervention A, 84 allocated to Intervention B Sex ratio: total: 124 (71.3%) males, 50 (28.7%) females Intervention A: 68 (75.6%) males, 22 (24.4%) females

	Intervention B: 56 (66.7%) males, 28 (33.3%) females
	Mean age: total: not reported
	Intervention A: 52 ± 10.4
	Intervention B: 52.7 ± 8.8
	Indication (no. (%)):
	Alcoholic cirrhosis: total: 84 (48.3%), Intervention A: 45 (50.0%), Intervention B: 39 (46.4%)
	HCV cirrhosis: total: 26 (14.9%), Intervention A: 12 (13.3%), Intervention B: 14 (16.7%)
	HBV cirrhosis: total: 12 (6.9%), Intervention A: 8 (8.9%), Intervention B: 4 (4.8%)
	Primary biliary cirrhosis: total: 11 (6.3%), Intervention A: 6 (6.7%), Intervention B: 5 (6.0%)
	Hepatocellular carcinoma: total: 11 (6.3%), Intervention A: 5 (5.6%), Intervention B: 6 (7.1%)
	Primary sclerosing cholangitis: total: 4 (2.3%), Intervention A: 1 (1.1%), Intervention B: 3 (3.6%)
	Other: total: 26 (14.9%), Intervention A: 13 (14.4%), Intervention B: 13 (15.5%)
	Type of donor: deceased donor
	Inclusion criteria: adult liver transplant recipients undergoing first cadaveric liver transplant
	Exclusion criteria: primary graft dysfunction, early retransplantation (before randomisation), renal insufficiency (creatinine > 200 ìmol/L), uncontrolled infection, multiorgan failure, cardiac arrest and presence of adenocarcinoma
Interventions	Intervention A: equivalent placebo
	Intervention B: prednisone: started on day 8 (dose and duration not reported)
	Concomitant immunosuppression:
	Basiliximab: 20 mg on day 0 and day 4
	Cyclosporine A: started within 24 hours of transplant aiming for trough levels of 200 ng/mL to 400 ng/mL from day 0 to 3 months and tapered to 150 ng/mL to 300 ng/mL
	Methylprednisolone: 500 mg intraoperatively, 200 mg on day 1, which was tapered to reach 20 mg on day 7
Outcomes	Mortality, graft loss, acute rejection, diabetes mellitus, recurrent hepatitis C, multiorgan failure, sepsis, intraabdominal haemorrhage, unsatisfactory therapeutic effect, hypertrichosis, surgical complications, renal failure, adverse events, CMV infection, CMV disease, infections, de novo malignancy, neurological complications, psychiatric complications, gastrointestinal disorders
Notes	Cross-over between intervention arms: no
	Sample size calculation: not reported
	Sources of funding: Novartis Pharma

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described

Pageaux 2004   *(Continued)*

Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote from the publication: "A prospective, 1-year, comparative, double-blind, placebo-controlled study, with informed consent and institutional review board approval, was conducted in 15 French liver transplantation centers." Comment: Double-blinded trial, both participants and medical staff blinded to treatment
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Comment: All outcome assessors including pathologists blinded
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "Supported by a grant from Novartis Pharma." Comment: Study is industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "There were no differences between the 2 groups concerning clinical characteristics and indications for transplantation (Table1). Independently of the diagnoses, 17 patients in each group had a positive hepatitis C virus serology. The 2 groups were similar in terms of Child-Turcotte-Pugh score, with a majority in stage C (40% in group 1 and 50% in group 2). After transplantation, the cyclosporine blood trough levels and the daily doses of corticosteroids / placebo were similar in the 2 groups (Table 2)." Comment: Study is free from baseline imbalance

Pelletier 2013

Methods	Trial design: randomised, single-centre, open-label clinical trial Mean follow-up: 2095 days ± 117 Study duration: 7 years, randomisation from June 2002 to May 2005 Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: Section of Transplant Surgery, University of Michigan, Michigan, USA Allocation of participants: 100 participants, 50 allocated to Intervention A, 50 allocated to Intervention B Sex ratio: total: 76 (76%) males, 24 (24%) females Intervention A: 38 (76%) males, 12 (24%) females Intervention B: 38 (76%) males, 12 (24%) females Mean age: total: not reported Intervention A: 54 ± 1 Intervention B: 56 ± 1 Indication (no. (%)): (some patients reported as having multiple indications) HCV cirrhosis: total: 54 (54%), Intervention A: 31 (62%), Intervention B: 23 (46%) Alcoholic cirrhosis: total: 42 (42%), Intervention A: 19 (38%), Intervention B: 23 (46%) Hepatocellular carcinoma: total: 20 (20%), Intervention A: 9 (18%), Intervention B: 11 (22%) Primary biliary cirrhosis or primary sclerosing cholangitis: total: 6 (6%), Intervention A: 1 (2%), Intervention B: 5 (10%) Cryptogenic cirrhosis: total: 15 (15%), Intervention A: 8 (16%), Intervention B: 7 (14%) Type of donor: not reported Inclusion criteria: all consecutive, consenting participants undergoing liver transplantation at the University of Michigan between June 2002 and May 2005 Exclusion criteria: participants aged < 18 years, multiple organ recipients and participants who required post-transplant steroid therapy for an indication other than prevention of rejection, such as autoimmune hepatitis or inflammatory bowel disease Other: BMI (kg/m^2): total: not reported, Intervention A: 30 ± 1, Intervention B: 29 ± 1 Pretransplant antihypertensive: total: 73 (73%), Intervention A: 36 (72%), Intervention B: 37 (74%) Pretransplant diabetes mellitus: total: 32 (32%), Intervention A: 20 (40%), Intervention B: 12 (24%) Pretransplant coronary artery disease: total: 8 (8%), Intervention A: 5 (10%), Intervention B: 3 (6%) Pretransplant haemodialysis: total: 4 (4%), Intervention A: 3 (6%), Intervention B: 1 (2%) MELD score: total: not reported, Intervention A: 16 ± 1, Intervention B: 18 ± 1 Warm ischaemia time (minutes): total: not reported, Intervention A: 64 ± 7, Intervention B: 54 ± 3 Cold ischaemia time (minutes): total: not reported, Intervention A: 518 ± 34, Intervention B: 518 ± 24 Donor age: total: Intervention A: 38 ± 3, Intervention B: 37 ± 2 Donor sex ratio: total: 68 (68%) males, 32 (32%) females; Intervention A: 31 (62%) males, 19 (38%) females; Intervention B: 37 (74%) males, 13 (26%) females Donor ethnicity: total: 80 (80%) white, 20 (20%) non-white; Intervention A: 39 (78%)

	white, 11 (22%) non-white; Intervention B: 41 (82%) white, 9 (18%) non-white Donor death from stroke: total: 50 (50%), Intervention A: 25 (50%), Intervention B: 25 (50%) Donor CMV positive: total: 67 (67%), Intervention A: 35 (70%), Intervention B: 32 (64%)
Interventions	Intervention A: no intervention Intervention B: Dexamethasone: 50 mg intraoperatively Prednisone: 3- to 6-month taper (dose not reported) Concomitant immunosuppression: Tacrolimus: started within 24 hours aiming for trough levels of 10 ng/mL to 15 ng/mL for days 0 to 30, 8 ng//mL to 12 ng/mL days 31 to 60, 4 ng/mL to 8 ng/mL from day 61 (tacrolimus withheld until day 4 in patients who received basiliximab induction) MMF: dose and timings not reported Basiliximab: intraoperatively and day 4 (dose not reported) given to 12 (24%) patients receiving Intervention A and 13 (26%) patients receiving Intervention B
Outcomes	Mortality, graft loss, acute rejection, time to first rejection, chronic rejection, recurrent hepatitis C, primary non-function, hepatic artery thrombosis, hepatic vein or IVC stenosis, biliary complications, postoperative acute renal failure, postoperative chronic renal failure, duration of high dependency stay, reoperation for bleeding, retransplantation, infections, surgical site infection, pneumonia, urinary tract infection, septicaemia, peritonitis, BMI, cholesterol, HDL, LDL, triglycerides, creatinine, diabetes mellitus, hypertension
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: Astellas Pharma Inc.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Low risk	Quote from the publication: "Enrolledcandidateswererandomizedtoeither the 'steroids' or 'no-steroids' groups using a closed-envelope system." Comment: Study used "closed envelope system"
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "All consecutive, consenting candidates undergoing liver transplantation at the University of Michigan between June 2002 and May 2005 were enrolled into a prospec-

		tive, open-label, randomized controlled trial (RCT) to evaluate the effects of complete steroids avoidance." Comment: Blinding of participants and medical staff not performed
Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "All consecutive, consenting candidates undergoing liver transplantation at the University of Michigan between June 2002 and May 2005 were enrolled into a prospective, open-label, randomized controlled trial (RCT) to evaluate the effects of complete steroids avoidance." Comment: Blinding of outcome assessors not performed
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "This study was supported by a grant from Astellas Pharma, Inc., Deerfield, IL, USA." Comment: No sample size calculation reported, study is industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "Donor and recipient characteristics are summarized in Table 1. The two groups of recipients were well matched with respect to gender, age, race, cause of liver failure, comorbidities, Model of End-stage Liver Disease (MELD) score, renal function and ischaemic times." Comment: Study is free from baseline imbalance

Ramirez 2013

Methods	Trial design: randomised, single-centre, open-label clinical trial Mean follow-up: 64.4 months (range: 10.6 to 79.6) Study duration: randomisation from February 2006 and November 2007 Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: Division of Transplantation, Department of Surgery, Thomas Jefferson University, Philadelphia, USA Allocation of participants: 40 participants, 20 allocated to Intervention A, 20 allocated to Intervention B Sex ratio: total: 25 (62.5%) males, 15 (37.5%) females Intervention A: 12 (60%) males, 8 (40%) females Intervention B: 13 (65%) males, 7 (35%) females Mean age: total: not reported Intervention A: 48.1 ± 4.3 Intervention B: 45.5 ± 3.5 Indication (no. (%)): HCV cirrhosis: total: 25 (62.5%), Intervention A: 11 (55.0%), Intervention B: 14 (70.0%) HBV cirrhosis: total: 4 (10.0%), Intervention A: 2 (10.0%), Intervention B: 2 (10.0%) Primary sclerosing cholangitis: total: 2 (5.0%), Intervention A: 2 (10.0%), Intervention B: 0 (0%) Hepatocellular carcinoma: total: 21 (52.5%), Intervention A: 10 (50.0%), Intervention B: 11 (55.0%) Alcoholic cirrhosis: total: 9 (22.5%), Intervention A: 3 (15.0%), Intervention B: 6 (30.0%) Non-alcoholic steatohepatitis: total: 1 (2.5%), Intervention A: 1 (5.0%), Intervention B: 0 (0%) Budd-Chiari syndrome: total: 1 (2.5%), Intervention A: 0 (0%), Intervention B: 1 (5.0%) Cryptogenic cirrhosis: total: 3 (7.5%), Intervention A: 2 (10.0%), Intervention B: 1 (5.0%) Type of donor: deceased donors Inclusion criteria: first adult liver transplant, age 18 to 72, cold ischaemic time < 20 hours Exclusion criteria: positive pregnancy test, previous organ transplant, multiple organ transplant recipients, women of childbearing potential not using the prescribed contraceptive methods, known sensitivity to basiliximab or class of basiliximab, participants with severe medical condition(s) that in the view of the investigator prohibits participation in the study, and use of any other investigational agent within 30 days prior to enrolment Other: Pretransplant MELD: total: not reported, Intervention A: 23.2 ± 1.5, Intervention B: 24.4 ± 2.0
Interventions	Intervention A: no intervention Intervention B: methylprednisolone: 1000 mg intraoperatively, then tapered to 50 mg 6-hourly on day 1, 40 mg 6-hourly on day 2, 30 mg 6-hourly on day 3, 20 mg 6-hourly on day 4, 20 mg 12-hourly on day 5 and then 20 mg once daily, tapered until stop at 6

	months Concomitant immunosuppression: Tacrolimus: started at 0.1 mg/kg aiming for 8 ng/mL to 12 ng/mL for 1 month and then 5 ng/mL to 8 ng/mL thereafter Mycophenolate mofetil: 1000 mg every 12 hours via nasogastric tube until tolerating oral medication after which 720 mg enteric-coated mycophenolate sodium twice daily orally for 3 months Basiliximab: 20 mg intraoperatively and on day 4 Prophylaxis: Ganciclovir or valganciclovir: 450 mg once daily for at least 3 months Trimethoprim sulfa: 3 times per week, dose and duration not reported Nystatin swish and swallow: 3 times daily, dose and duration not reported
Outcomes	Mortality, graft loss, acute rejection, infection, CMV infection, recurrent hepatitis C, severity of HCV recurrence, diabetes mellitus, hypertension, weight, cholesterol, mean arterial pressure, fasting blood glucose, ALT, AST, bilirubin
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: Novartis Corporation

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from the publication: "Randomization was performed by the TJUH Investigational Drug Pharmacy Service who dispensed study drug based on the computer-generated randomization schedule and the study protocol." Comment: Computer-generated randomisation
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "Between February 2006 and November 2007, 40 adult recipients of deceased donor primary OLT at TJUH were enrolled into this prospective, controlled, randomized, non-blinded, pilot trial (Clinical Trials.gov; ID: NCT00296244)." Comment: Blinding of participants and medical staff not performed

Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "Between February 2006 and November 2007, 40 adult recipients of deceased donor primary OLT at TJUH were enrolled into this prospective, controlled, randomized, non-blinded, pilot trial (Clinical Trials.gov; ID: NCT00296244)." Comment: Blinding of outcome assessors not performed
Incomplete outcome data (attrition bias)	Low risk	Quote from the publication: "Between February 2006 and November 2007, 40 adult OLT recipients were enrolled in the study and 20 recipients were randomized to each group. One recipient in the CS-free group required a retransplantation for hepatic artery thrombosis on post-OLT day 16. Because he expired within 10 d after re-transplantation, follow-up data were short and untenable, and therefore, he was excluded from the study analysis (Fig. 1)." Comment: One withdrawal and reason for the withdrawal adequately described
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "The authors would like to acknowledge Novartis Corporation for providing financial grant to conduct the clinical trial." Comment: No sample size calculation reported; study is industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "Donor characteristics were comparable between the two groups (Table 1). Other than a significantly higher mean recipient age and longer median hospital stay in CS-free (23 d) compared with CS group (15 d), recipient demographics and peri-operative data were similar between the two groups." Comment: Baseline imbalance is unlikely to significantly affect outcomes

Reggiani 2005

Methods	Trial design: randomised, single-centre, open-label clinical trial
	Mean follow-up: 31 ± 7 months
	Study duration: not reported
	Language: English
	Type of information: journal article
	Judgement on quality: high risk

Participants	Setting: IRCCS Ospedale Maggiore, Milan, Italy
	Allocation of participants: 30 participants, 18 allocated to Intervention A, 12 allocated to Intervention B
	Sex ratio: total: 21 (70%) males, 9 (30%) females
	Intervention A: 13 (72.2%) males, 5 (27.8%) females
	Intervention B: 8 (66.7%) males, 4 (33.3%) females
	Mean age: total: not reported
	Intervention A: 50.4 ± 8.9
	Intervention B: 49.7 ± 4.6
	Indication (no. (%)):
	HCV or HBV cirrhosis: total: 21 (70.0%), Intervention A: 14 (77.8%), Intervention B: 7 (58.3%)
	Alcoholic cirrhosis: total: 3 (10.0%), Intervention A: 1 (5.6%), Intervention B: 2 (16.7%)
	Haemochromatosis: total: 2 (6.7%), Intervention A: 1 (5.6%), Intervention B: 1 (8.3%)
	Primary biliary cirrhosis: total: 1 (3.3%), Intervention A: 1 (5.6%), Intervention B: 0 (0.0%)
	Acute liver failure: total: 1 (3.3%), Intervention A: 1 (5.6%), Intervention B: 0 (0.0%)
	Cryptogenic cirrhosis: total: 1 (3.3%), Intervention A: 0 (0.0%), Intervention B: 1 (8.3%)
	Polycystic liver disease: total: 1 (3.3%), Intervention A: 0 (0.0%), Intervention B: 1 (8.3%)
	Type of donor: not reported
	Inclusion criteria: not reported
	Exclusion criteria: not reported
	Other:
	Hepatocellular carcinoma: total: 14 (46.7%), Intervention A: 12 (66.7%), Intervention B: 2 (16.7%)

Interventions	Intervention A: methylprednisolone: no intervention
	Intervention B: 1000 mg intraoperatively then 200 mg/day tapered to 40 mg/day at day 5, 20 mg on day 6 then tapered to stop at 3 months
	Concomitant immunosuppression:
	Tacrolimus: started at 0.1 mg/kg aiming for trough levels of 10 ng/mL to 15 ng/mL for 2 weeks then 8 ng/mL to 10 ng/mL thereafter
	Mycophenolate mofetil: 750 mg twice daily for 1 month, 500 mg twice daily thereafter

Outcomes	Mortality, surgical complications, tacrolimus levels, MMF levels, acute rejection, graft loss, infections, diarrhoea, "peptic symptoms", impaired renal function, leukopenia, thrombocytopenia, anaemia, neurotoxicity, diabetes mellitus, hypertension

Glucocorticosteroid-free versus glucocorticosteroid-containing immunosuppression for liver transplanted patients (Review) 76

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "To assess the efficacy and safety or a primary immunosuppressive regimen with tacrolimus (Tac) and low-dose mycophenolate mofetil (MMF) without steroids and to determine the exposure to mycophenolic acid (MPA) in the early post-operative period, we performed a single-center, randomized 1:1, open-label, controlled study planned to be 60 liver transplantation patients randomized into 2 groups: group A, tacrolimus + MMF (750 mg orally twice a day); and group B, tacrolimus + MMF (750 mg orally twice a day) + steroids." Comment: Blinding of participants and medical staff not performed
Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "To assess the efficacy and safety or a primary immunosuppressive regimen with tacrolimus (Tac) and low-dose mycophenolate mofetil (MMF) without steroids and to determine the exposure to mycophenolic acid (MPA) in the early post-operative period, we performed a single-center, randomized 1:1, open-label, controlled study planned to be 60 liver transplantation patients randomized into 2 groups: group A, tacrolimus + MMF (750 mg orally twice a day); and group B, tacrolimus + MMF (750 mg orally twice a day) + steroids." Comment: Blinding of outcome assessors not performed

Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Low risk	Comment: All specified outcomes appear to be reported
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	High risk	Quote from the publication: "Patient enrollment was stopped after an interim analysis by the Ethical Committee." Comment: Study stopped early due to data dependent process (interim analysis)
Free of baseline imbalance?	High risk	Quote from the publication: "Hepatocellular carcinoma was diagnosed in 2 (16.7%) patients in group A and in 12 (66.7%) patients in group B." Comment: Significantly increased rates of pretransplant hepatocellular carcinoma in Intervention B

Studenik 2005

Methods	Trial design: randomised, single-centre clinical trial Mean follow-up: 13 months (range: 2 to 23) Study duration: not reported Language: English Type of information: abstract Judgement on quality: unclear risk
Participants	Setting: Brno, Czech Republic Allocation of participants: 39 participants, 19 allocated to Intervention A, 20 allocated to Intervention B Sex ratio: total: not reported Intervention A: not reported Intervention B: not reported Mean age: total: not reported Intervention A: not reported Intervention B: not reported Indication (no. (%)): not reported Type of donor: not reported Inclusion criteria: not reported Exclusion criteria: not reported Other: baseline characteristics reported as comparable

Interventions	Intervention A: no intervention Intervention B: 9-month glucocorticosteroid taper (dose, duration and type of gluco-corticosteroid medication not reported) Concomitant immunosuppression: Tacrolimus: dose and duration not reported Mycophenolate mofetil: dose and duration not reported Hydrocortisone: 500 mg intraoperatively Daclizumab: 1 mg/kg intraoperatively then 1 mg/kg 2 to 7 days later depending on initial dose effect on CD25 expression on peripheral T-lymphocytes
Outcomes	Mortality, graft loss, acute rejection, hypertension, diabetes mellitus, CMV infection, leucopenia and CD25 expression on peripheral T lymphocytes
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Unclear risk	Comment: Study protocol not available and results only published in abstract
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Unclear risk	Comment: Study only published in abstract

Free of baseline imbalance?	Low risk	Quote from the publication: "Both groups were comparable in all observed indicators." Comment: Study is reported as being free from baseline imbalance

Tisone 1999

Methods	Trial design: randomised, single-centre, open-label clinical trial Mean follow-up: 108 ± 4 months Study duration: 10 years from randomisation Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: Ospedale S. Eugenio, Piazzale dell'Umanesimo, Rome, Italy Allocation of participants: 45 participants, 22 allocated to Intervention A, 23 allocated to Intervention B Sex ratio: total: 34 (75.6%) males, 11 (24.4%) females Intervention A: 16 (72.7%) males, 6 (26.1%) females Intervention B: 18 (72%) males, 5 (21.7%) females Mean age: total: not reported Intervention A: 49.0 ± 9.8 Intervention B: 50.5 ± 6.2 Indication (no. (%)): HCV cirrhosis: total: 15 (33.3%), Intervention A: 8 (36.4%), Intervention B: 7 (30.4%) HBV cirrhosis: total: 13 (28.9%), Intervention A: 7 (31.8%), Intervention B: 6 (26.1%) Alcoholic cirrhosis: total: 6 (13.3%), Intervention A: 2 (9.1%), Intervention B: 4 (17.4%) Cryptogenic cirrhosis and others: total: 11 (24.4%), Intervention A: 5 (22.7%), Intervention B: 6 (26.1%) Type of donor: not reported Inclusion criteria: adult liver transplant recipients (> 20 years of age and < 62), HBsAg-positive participants were only considered for inclusion if repeatedly HBV-DNA negative Exclusion criteria: positive HIV serology, positive for IgM anti-cytomegalovirus, HBV-DNA-positive participants Other: Donor age: total: not reported, Intervention A: 38.3 ± 14, Intervention B: 35.3 ± 16 Donor sex ratio: total: 30 (66.7%) male, 15 (33.3%) female; Intervention A: 13 (59.1%) males, 9 (39.1%) females; Intervention A: 17 (73.9%) males, 6 (26.1%) females Cold ischaemia time (hours): total: not reported, Intervention A: 6.2+/-2.8, Intervention B: 6.4+/-1.8 Possible selective outcome reporting: hypertension is not reported in any of the relevant publications
Interventions	Intervention A: No intervention

	Intervention B: Methylprednisolone: 20 mg/day (duration not reported) Prednisone: (starting from withdrawal of methylprednisolone) 20 mg/day until day 30 then tapered "gradually" to 5 mg/day and stopped at 3 months Concomitant immunosuppression: Cyclosporine A: aiming for trough levels of 350 ng/mL to 450 ng/mL for "the first few months" then 250 ng/mL to 350 ng/mL thereafter Azathioprine: 1 to 1.5 mg/day (duration not reported)
Outcomes	Mortality, graft loss, acute rejection, primary non-function, poor initial function, normal function, chronic rejection, infection, CMV infection, recurrent hepatitis C, renal failure (requiring dialysis), AST, bilirubin, alkaline phosphatase, GGT, creatinine, cyclosporine serum levels, time in intensive treatment unit, time in hospital, glucose, cholesterol
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: not reported

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote from the publication: "Patients were randomly assigned, using a computer-generated list, to receive a standard immunosuppressive therapy composed of cyclosporine microemulsion (Neoral), in doses to maintain trough whole-blood levels (monoclonal fluorescence assay) of 350-450 ng/ml during the first months and 250-350 ng/ml thereafter, and azathioprine (1-1.5 mg/day), with (group A) or without (group B) corticosteroids." Comment: Computer-generated randomisation
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "To address the latter points, we conducted a prospective open-label randomized pilot study on a consecutive series of patients undergoing orthotopic liver transplantation (OLTx) at our institution." Comment: Blinding of participants and medical staff not performed

Tisone 1999 *(Continued)*

Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "To address the latter points, we conducted a prospective open-label randomized pilot study on a consecutive series of patients undergoing orthotopic liver transplantation (OLTx) at our institution." Comment: Blinding of outcome assessors not performed
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported
Selective reporting (reporting bias)	Unclear risk	Comment: Study does not report hypertension despite mentioning this as a potential complication of glucocorticosteroid use in both the introduction and the discussion sections
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Quote from the publication: "As summarized in Table 1, the two groups did not differ in the demographic or clinical features of donors and recipients, or in the duration of cold ischemia. In particular, there were no differences in the UNOS status or in the hemodynamic data and the laboratory findings related to liver and kidney function between the two groups." Comment: Study free from baseline imbalance

Vivarelli 2007

Methods	Trial design: randomised, multicentre, open-label clinical trial Mean follow-up: 841 days (range: 130 to 1376) Study duration: not reported Language: English Type of information: journal article Judgement on quality: high risk
Participants	Setting: 2 transplantation centres in Italy Allocation of participants: 47 participants, 22 allocated to Intervention A, 25 allocated to Intervention B Sex ratio: total: not reported

	Intervention A: not reported Intervention B: not reported Mean age: total: not reported Intervention A: 58.9 (range: 43 to 66) Intervention B: 57.2 (range: 41 to 67) Indication (no. (%)): HCV cirrhosis: total: 47 (100.0%), Intervention A: 22 (100.0%), Intervention B: 25 (100.0%) Type of donor: deceased donors Inclusion criteria: HCV positive first-time whole liver recipients from deceased donors Exclusion criteria: HBsAg-positive, previous transplant, partial grafts, living donors Other: HCV-RNA titres (Meq/mL): total: not reported, Intervention A: 0.755 (range: < 0.003 to 4.3), Intervention B: 0.765 (< 0.003 to 8.04) MELD score: total: not reported, Intervention A: 16 (range: 8 to 25), Intervention B: 15 (range: 7 to 28) Pretransplant diabetes mellitus: total: 11 (23.4%), Intervention A: 5 (22.7%), Intervention B: 6 (24.0%)
Interventions	Intervention A: prednisone: tapered from 25 mg/day to 15 mg/day from days 6 to day 30, 15 mg/day on days 31 to 45, 10 mg/day on days 46 to 60, 5 mg/day on days 61 to 75, 2.5 mg/day on days 76 to 90) and stopped at day 91 Intervention B: prednisone: 25 mg/day on day 6 tapered to 15 mg/day by day 31, 15 mg/day on days 31 to 90, 10 mg/day on days 91 to day 180, 7.5 mg/day on days 181 to 270, 5 mg/day from day 271 to the end of the first postoperative year, 2.5 mg for the second postoperative year and stopped at the end of the second postoperative year Concomitant immunosuppression: Methylprednisolone: intraoperatively and on days 1 to 5 (dose not reported) Tacrolimus: aiming for trough level of 5 ng/mL to 15 ng/mL for the first 3 months and then 5 ng/mL to 10 ng/mL thereafter
Outcomes	Mortality, graft loss, acute rejection, treatment failure, recurrent hepatitis C, HCV-RNA levels, Scheuer fibrosis, acute rejection requiring steroids, acute rejection requiring multiple steroids, need for antiviral treatment (anti-HCV), diabetes mellitus, tacrolimus levels
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: Astellas Pharma Italia

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described
Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described

Vivarelli 2007   *(Continued)*

Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote from the publication: "The study was conducted at the Liver Transplant Centres of Bologna and Padua, Italy, in an open-label, not-blinded, prospective and randomized fashion." Comment: Blinding of participants and medical staff not performed
Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote from the publication: "The study was conducted at the Liver Transplant Centres of Bologna and Padua, Italy, in an open-label, not-blinded, prospective and randomized fashion." Comment: Blinding of outcome assessors not performed
Incomplete outcome data (attrition bias)	Low risk	Quote from the publication: "Median follow-up was 841 days (130-1376); apart from those who died or lost their graft earlier, all patients had at least 2 year follow-up." Comment: Missing data unlikely to affect outcome results
Selective reporting (reporting bias)	Low risk	Comment: All outcomes appear to be fully reported
Other bias	High risk	Quote from the publication: "The authors declare that FG is employed by Astellas Pharma Italia and he coordinated the Centres involved in the study and helped in the data collection. Astellas Pharma Italia supported the study financially and coordinated the Centres involved (EPASTER Study, investigator originated and driven)." Comment: No sample size calculation reported; study industry sponsored
Free of early stopping?	Low risk	Comment: Study not stopped early
Free of baseline imbalance?	Low risk	Comment: Baseline characteristics are listed in Table 1. All listed characteristics are similar between the groups with P values > 0.05. Study is free from baseline imbalance

Zhong 2010

Methods	Trial design: randomised, multicentre, double-blinded, placebo-controlled clinical trial Mean follow-up: not reported Study duration: not reported Language: English Type of information: abstract (abstract appears to present preliminary data for the first 182 participants randomised) Judgement on quality: unclear risk
Participants	Setting: Shanghai First People's Hospital Allocation of participants: target enrolment of 300 participants, current participants not adequately reported (*study ongoing*) Sex ratio: total: not reported Intervention A: not reported Intervention B: not reported Mean age: total: not reported Intervention A: not reported Intervention B: not reported Indication (no. (%)): (hepatocellular carcinoma primary indication for all transplants) Hepatocellular carcinoma: total: not reported (100%), Intervention A: not reported (100%), Intervention B: not reported (100%) Type of donor: not reported Inclusion criteria: liver transplant recipients with hepatocellular carcinoma Exclusion criteria: death within 3 months of transplantation, inability to provide written informed consent prior to study entry
Interventions	Intervention A: no intervention Intervention B: methylprednisolone 10 mg/kg intraoperatively and a further 10 mg/kg given over 1 week Concomitant immunosuppression: Tacrolimus/cyclosporine A: dose not reported (NOTE: published abstract reports use of cyclosporine A, register on clinicaltrials.gov reports use of tacrolimus) Basiliximab: 20 mg given twice (timings not reported)
Outcomes	Mortality, graft loss, acute rejection, infection, bacterial infection, de novo diabetes mellitus, recurrent hepatitis B, hypertension, neurological complications, tumour size, tumour differentiation, histological staging of tumour, recurrence-free survival
Notes	Cross-over between intervention arms: no Sample size calculation: not reported Sources of funding: Shanghai Jiao Tong University School of Medicine

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Comment: Generation of randomisation sequence not described

Allocation concealment (selection bias)	Unclear risk	Comment: Allocation concealment not described
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Comment: Blinding of participants and medical staff not described
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Comment: Blinding of outcome assessors not described
Incomplete outcome data (attrition bias)	Unclear risk	Comment: Number of withdrawals and reasons for withdrawal not reported, estimated enrolment not achieved and results only published in abstract
Selective reporting (reporting bias)	High risk	Comment: Results only published in abstract, graft survival not reported
Other bias	Unclear risk	Comment: No sample size calculation reported
Free of early stopping?	Unclear risk	Comment: Study only published in abstract
Free of baseline imbalance?	Unclear risk	Comment: Baseline characteristics not described, presence or absence of baseline imbalance not reported

ABO: blood group
ALT: alanine aminotransferase
AST: aspartate aminotransferase
BMI: body mass index
CMV: cytomegalovirus
GGT: gamma-glutamyl transferase
HBsAg: hepatitis B surface antigen
HBV: hepatitis B virus
HCC: hepatocellular carcinoma
HCV: hepatitis C virus
HDL: high density lipoprotein
HIV: human immunodeficiency virus
HSV: herpes simplex virus
IgM: immunoglobulin M
IVC: inferior vena cava
LDL: low density lipoprotein
MELD: model for end-stage liver disease
MMF: mycophenolate mofetil
NAFLD: non-alcoholic fatty liver disease

RCT: randomised clinical trial

Characteristics of excluded studies *[ordered by study ID]*

Study	Reason for exclusion
Benitez 2010	Randomised clinical trial comparing RATG with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Boillot 2005	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Cosimi 1987	Randomised clinical trial comparing muromonab CD3 with glucocorticosteroids for treatment of acute rejection; no comment on glucocorticosteroid avoidance or withdrawal possible
Cuervas-Mons 2009	Randomised clinical trial comparing mycophenolate mofetil with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Day 2004	Randomised clinical trial comparing continuation of tacrolimus monotherapy with tacrolimus discontinuation and replacement with mycophenolate mofetil and glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
De Simone 2007	Randomised clinical trial comparing basiliximab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Filipponi 2004	Method reports study as a randomised clinical trial with ITT. Results are reported instead as a per-treatment analysis with patients moved between arms for analysis as a result of a data-dependent process. This does not appear to have been carried out using pre-specified criteria. Our inclusion criteria state that we are only considering randomised clinical trials that present their data in an ITT analysis for this review. We made attempts to contact the author to request the original data so that ITT analysis could be completed
Foroncewicz 2009	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Ganschow 2007	Randomised clinical trial comparing high- and low-dose glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Hu 2013	Non-randomised clinical trial comparing multiple immunosuppression regimens
Jonas 2001	Randomised clinical trial comparing tacrolimus-based dual therapy with cyclosporine A-based quadruple therapy in which glucocorticosteroid withdrawal was assessed as an outcome; no comment on glucocorticosteroid avoidance or withdrawal possible
Junge 2005	Randomised clinical trial comparing mycophenolate mofetil with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible

Kato 2007	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Klintmalm 2011	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Lupo 2008	Randomised clinical trial comparing basiliximab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Manousou 2009	Randomised clinical trial comparing monotherapy of tacrolimus with triple therapy of tacrolimus, azathioprine and glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
McDiarmid 1995	Randomised clinical trial comparing glucocorticosteroid continuation with glucocorticosteroid withdrawal over 1 year post-transplant; investigation of alteration in an existing immunosuppression strategy rather than a primary immunosuppression strategy
Nair 2006	Randomised clinical trial comparing RATG with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Nair 2008	Randomised clinical trial comparing PEG interferon alpha 2b, ribavirin and amantadine with PEG interferon alpha 2b and ribavirin in 2 glucocorticosteroid-free arms; no comment on glucocorticosteroid avoidance or withdrawal possible
Neumann 2012	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Otero 2009	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Saliba 2012	Randomised clinical trial comparing concentration-controlled mycophenolate mofetil with fixed-dose mycophenolate mofetil and glucocorticosteroids; differences in concomitant immunosuppression therefore no comment on glucocorticosteroid avoidance or withdrawal possible
Spada 2006	Randomised clinical trial comparing basiliximab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Takada 2013	Randomised clinical trial comparing mycophenolate mofetil with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible
Teisseyre 2006	Randomised clinical trial comparing saline with methylprednisolone for prevention of ischaemia reperfusion injury; no comment on glucocorticosteroid avoidance or withdrawal for post-transplantation immunosuppression possible
Turner 2006	Randomised clinical trial comparing RATG with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible

Washburn 2001	Randomised clinical trial comparing daclizumab with glucocorticosteroids; no comment on glucocorticosteroid avoidance or withdrawal possible

ITT: intention-to-treat
Muromonab CD3: muromonab cluster of differentiation 3
PEG: pegylated
RATG: rabbit antithymocyte globulin

DATA AND ANALYSES

Comparison 1. Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Mortality	15	1323	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.93, 1.44]
1.1 Glucocorticosteroid avoidance	9	758	Risk Ratio (M-H, Fixed, 95% CI)	1.11 [0.84, 1.48]
1.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	1.22 [0.86, 1.72]
2 Graft loss including death	11	1002	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.90, 1.46]
2.1 Glucocorticosteroid avoidance	8	671	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.77, 1.39]
2.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	1.44 [0.93, 2.24]
3 Acute rejection	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.33 [1.08, 1.64]
3.1 Glucocorticosteroid avoidance	10	782	Risk Ratio (M-H, Fixed, 95% CI)	1.37 [1.04, 1.81]
3.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	1.28 [0.93, 1.76]
4 Infection	8	778	Risk Ratio (M-H, Fixed, 95% CI)	0.88 [0.73, 1.05]
4.1 Glucocorticosteroid avoidance	6	500	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.80, 1.15]
4.2 Glucocorticosteroid withdrawal	2	278	Risk Ratio (M-H, Fixed, 95% CI)	0.41 [0.19, 0.90]
5 Chronic rejection	9	974	Risk Ratio (M-H, Fixed, 95% CI)	1.08 [0.56, 2.10]
5.1 Glucocorticosteroid avoidance	6	586	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.32, 2.08]
5.2 Glucocorticosteroid withdrawal	3	388	Risk Ratio (M-H, Fixed, 95% CI)	1.45 [0.55, 3.78]
6 Glucocorticosteroid-resistant rejection	10	1020	Risk Ratio (M-H, Fixed, 95% CI)	2.14 [1.13, 4.02]
6.1 Glucocorticosteroid avoidance	7	689	Risk Ratio (M-H, Fixed, 95% CI)	1.88 [0.89, 3.98]
6.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	2.86 [0.86, 9.49]
7 Diabetes mellitus	12	1185	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.66, 0.99]
7.1 Glucocorticosteroid avoidance	7	674	Risk Ratio (M-H, Fixed, 95% CI)	0.90 [0.70, 1.17]
7.2 Glucocorticosteroid withdrawal	5	511	Risk Ratio (M-H, Fixed, 95% CI)	0.68 [0.50, 0.94]
8 CMV	7	786	Risk Ratio (M-H, Fixed, 95% CI)	0.74 [0.48, 1.16]
8.1 Glucocorticosteroid avoidance	5	502	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.39, 1.49]
8.2 Glucocorticosteroid withdrawal	2	284	Risk Ratio (M-H, Fixed, 95% CI)	0.73 [0.41, 1.30]

9 HCV recurrence	10	477	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.92, 1.15]
9.1 Glucocorticosteroid avoidance	7	274	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.84, 1.08]
9.2 Glucocorticosteroid withdrawal	3	203	Risk Ratio (M-H, Fixed, 95% CI)	1.18 [0.96, 1.44]
10 Malignancy	3	528	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.16, 1.74]
10.1 Glucocorticosteroid avoidance	2	354	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.13, 2.08]
10.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	0.54 [0.05, 5.80]
11 Post-transplant lymphoproliferative disorder	2	330	Risk Ratio (M-H, Fixed, 95% CI)	2.39 [0.36, 15.95]
11.1 Glucocorticosteroid avoidance	1	156	Risk Ratio (M-H, Fixed, 95% CI)	2.0 [0.19, 21.61]
11.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	3.21 [0.13, 77.77]
12 Renal insufficiency	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.73, 1.19]
12.1 Glucocorticosteroid avoidance	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.73, 1.19]
13 Creatinine	4	309	Mean Difference (IV, Fixed, 95% CI)	0.11 [0.07, 0.16]
13.1 Glucocorticosteroid avoidance	2	145	Mean Difference (IV, Fixed, 95% CI)	0.15 [0.10, 0.20]
13.2 Glucocorticosteroid withdrawal	2	164	Mean Difference (IV, Fixed, 95% CI)	-0.06 [-0.16, 0.05]
14 Hypertension	10	1098	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.65, 0.90]
14.1 Glucocorticosteroid avoidance	6	634	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.66, 1.00]
14.2 Glucocorticosteroid withdrawal	4	464	Risk Ratio (M-H, Fixed, 95% CI)	0.71 [0.55, 0.91]
15 Hyperlipidaemia	4	400	Risk Ratio (M-H, Fixed, 95% CI)	0.75 [0.38, 1.48]
15.1 Glucocorticosteroid avoidance	2	150	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.45, 2.52]
15.2 Glucocorticosteroid withdrawal	2	250	Risk Ratio (M-H, Fixed, 95% CI)	0.44 [0.14, 1.41]
16 Cholesterol	6	611	Mean Difference (IV, Fixed, 95% CI)	-18.49 [-22.02, -14.96]
16.1 Glucocorticosteroid avoidance	3	343	Mean Difference (IV, Fixed, 95% CI)	-18.33 [-21.93, -14.72]
16.2 Glucocorticosteroid withdrawal	3	268	Mean Difference (IV, Fixed, 95% CI)	-22.06 [-38.94, -5.18]
17 Hypercholesterolaemia	2	266	Risk Ratio (M-H, Fixed, 95% CI)	0.56 [0.32, 1.00]
17.1 Glucocorticosteroid avoidance	1	156	Risk Ratio (M-H, Fixed, 95% CI)	1.2 [0.55, 2.61]
17.2 Glucocorticosteroid withdrawal	1	110	Risk Ratio (M-H, Fixed, 95% CI)	0.21 [0.08, 0.59]

Comparison 2. Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression (CNI subgroups)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Mortality	15	1323	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.93, 1.44]
1.1 Tacrolimus	11	802	Risk Ratio (M-H, Fixed, 95% CI)	1.17 [0.92, 1.51]
1.2 Cyclosporine A	4	521	Risk Ratio (M-H, Fixed, 95% CI)	1.10 [0.69, 1.74]
2 Graft loss including death	11	1002	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.90, 1.46]
2.1 Tacrolimus	8	585	Risk Ratio (M-H, Fixed, 95% CI)	1.12 [0.85, 1.47]
2.2 Cyclosporine A	3	417	Risk Ratio (M-H, Fixed, 95% CI)	1.23 [0.72, 2.09]
3 Acute rejection	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.33 [1.08, 1.64]
3.1 Tacrolimus	11	802	Risk Ratio (M-H, Fixed, 95% CI)	1.35 [1.02, 1.77]
3.2 Cyclosporine A	5	545	Risk Ratio (M-H, Fixed, 95% CI)	1.30 [0.94, 1.80]
4 Infection	8	778	Risk Ratio (M-H, Fixed, 95% CI)	0.88 [0.73, 1.05]
4.1 Tacrolimus	4	257	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.72, 1.27]
4.2 Cyclosporine A	4	521	Risk Ratio (M-H, Fixed, 95% CI)	0.83 [0.66, 1.05]
5 Chronic rejection	9	974	Risk Ratio (M-H, Fixed, 95% CI)	1.08 [0.56, 2.10]
5.1 Tacrolimus	4	429	Risk Ratio (M-H, Fixed, 95% CI)	1.10 [0.44, 2.76]
5.2 Cyclosporine A	5	545	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.41, 2.76]
6 Glucocorticosteroid-resistant rejection	10	1020	Risk Ratio (M-H, Fixed, 95% CI)	2.14 [1.13, 4.02]
6.1 Tacrolimus	7	603	Risk Ratio (M-H, Fixed, 95% CI)	2.46 [1.01, 5.97]
6.2 Cyclosporine A	3	417	Risk Ratio (M-H, Fixed, 95% CI)	1.83 [0.74, 4.55]
7 Diabetes mellitus	12	1185	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.66, 0.99]
7.1 Tacrolimus	9	709	Risk Ratio (M-H, Fixed, 95% CI)	0.91 [0.72, 1.15]
7.2 Cyclosporine A	3	476	Risk Ratio (M-H, Fixed, 95% CI)	0.61 [0.41, 0.90]
8 CMV infection	7	786	Risk Ratio (M-H, Fixed, 95% CI)	0.74 [0.48, 1.16]
8.1 Tacrolimus	4	369	Risk Ratio (M-H, Fixed, 95% CI)	0.79 [0.46, 1.38]
8.2 Cyclosporine A	3	417	Risk Ratio (M-H, Fixed, 95% CI)	0.68 [0.33, 1.40]
9 HCV recurrence	10	477	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.92, 1.15]
9.1 Tacrolimus	5	194	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.84, 1.16]
9.2 Cyclosporine A	5	283	Risk Ratio (M-H, Fixed, 95% CI)	1.07 [0.92, 1.23]
10 Malignancy	3	528	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.16, 1.74]
10.1 Tacrolimus	1	156	Risk Ratio (M-H, Fixed, 95% CI)	5.0 [0.24, 102.49]
10.2 Cyclosporine A	2	372	Risk Ratio (M-H, Fixed, 95% CI)	0.21 [0.04, 1.22]
11 Post-transplant lymphoproliferative disorder	2	330	Risk Ratio (M-H, Fixed, 95% CI)	2.39 [0.36, 15.95]
11.1 Tacrolimus	1	156	Risk Ratio (M-H, Fixed, 95% CI)	2.0 [0.19, 21.61]
11.2 Cyclosporine A	1	174	Risk Ratio (M-H, Fixed, 95% CI)	3.21 [0.13, 77.77]
12 Renal insufficiency	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.73, 1.19]
12.1 Tacrolimus	3	249	Risk Ratio (M-H, Fixed, 95% CI)	1.09 [0.73, 1.64]
12.2 Cyclosporine A	1	198	Risk Ratio (M-H, Fixed, 95% CI)	0.85 [0.63, 1.16]
13 Creatinine	4	309	Mean Difference (IV, Fixed, 95% CI)	0.11 [0.07, 0.16]
13.1 Tacrolimus	3	264	Mean Difference (IV, Fixed, 95% CI)	0.17 [0.12, 0.22]
13.2 Cyclosporine A	1	45	Mean Difference (IV, Fixed, 95% CI)	-0.10 [-0.19, -0.01]
14 Hypertension	10	1098	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.65, 0.90]
14.1 Tacrolimus	7	622	Risk Ratio (M-H, Fixed, 95% CI)	0.83 [0.65, 1.06]
14.2 Cyclosporine A	3	476	Risk Ratio (M-H, Fixed, 95% CI)	0.71 [0.58, 0.88]
15 Hyperlipidaemia	4	400	Risk Ratio (M-H, Fixed, 95% CI)	0.75 [0.38, 1.48]
15.1 Tacrolimus	3	226	Risk Ratio (M-H, Fixed, 95% CI)	0.94 [0.44, 2.02]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
15.2 Cyclosporine A	1	174	Risk Ratio (M-H, Fixed, 95% CI)	0.36 [0.07, 1.72]
16 Cholesterol	6	611	Mean Difference (IV, Fixed, 95% CI)	-18.49 [-22.02, -14.96]
16.1 Tacrolimus	3	264	Mean Difference (IV, Fixed, 95% CI)	-18.38 [-22.09, -14.67]
16.2 Cyclosporine A	3	347	Mean Difference (IV, Fixed, 95% CI)	-19.56 [-31.05, -8.07]

Comparison 3. Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression (antiproliferative subgroups)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Mortality	15	1323	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.93, 1.44]
1.1 No antiproliferative agent	8	928	Risk Ratio (M-H, Fixed, 95% CI)	1.24 [0.92, 1.66]
1.2 Mycophenolate mofetil	6	350	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.75, 1.51]
1.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.40, 2.28]
2 Graft loss including death	11	1002	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.90, 1.46]
2.1 No antiproliferative agent	6	748	Risk Ratio (M-H, Fixed, 95% CI)	1.12 [0.82, 1.52]
2.2 Mycophenolate mofetil	4	209	Risk Ratio (M-H, Fixed, 95% CI)	1.27 [0.82, 1.96]
2.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.40, 2.28]
3 Acute rejection	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.33 [1.08, 1.64]
3.1 No antiproliferative agent	9	952	Risk Ratio (M-H, Fixed, 95% CI)	1.23 [0.97, 1.56]
3.2 Mycophenolate mofetil	6	350	Risk Ratio (M-H, Fixed, 95% CI)	1.87 [1.15, 3.04]
3.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.27, 3.36]
4 Infection	8	778	Risk Ratio (M-H, Fixed, 95% CI)	0.88 [0.73, 1.05]
4.1 No antiproliferative agent	3	476	Risk Ratio (M-H, Fixed, 95% CI)	0.78 [0.59, 1.02]
4.2 Mycophenolate mofetil	4	257	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.72, 1.27]
4.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	1.08 [0.75, 1.58]
5 Chronic rejection	9	974	Risk Ratio (M-H, Fixed, 95% CI)	1.08 [0.56, 2.10]
5.1 No antiproliferative agent	7	829	Risk Ratio (M-H, Fixed, 95% CI)	1.35 [0.66, 2.79]
5.2 Mycophenolate mofetil	1	100	Risk Ratio (M-H, Fixed, 95% CI)	0.25 [0.03, 2.16]
5.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
6 Glucocorticosteroid-resistant rejection	10	1020	Risk Ratio (M-H, Fixed, 95% CI)	2.14 [1.13, 4.02]
6.1 No antiproliferative agent	6	748	Risk Ratio (M-H, Fixed, 95% CI)	2.14 [1.13, 4.02]
6.2 Mycophenolate mofetil	3	227	Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
6.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
7 Diabetes mellitus	12	1185	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.66, 0.99]
7.1 No antiproliferative agent	8	928	Risk Ratio (M-H, Fixed, 95% CI)	0.79 [0.62, 1.00]
7.2 Mycophenolate mofetil	4	257	Risk Ratio (M-H, Fixed, 95% CI)	0.86 [0.59, 1.25]
8 CMV infection	7	786	Risk Ratio (M-H, Fixed, 95% CI)	0.74 [0.48, 1.16]
8.1 No antiproliferative agent	5	701	Risk Ratio (M-H, Fixed, 95% CI)	0.71 [0.45, 1.12]
8.2 Mycophenolate mofetil	1	40	Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
8.3 Azathioprine	1	45	Risk Ratio (M-H, Fixed, 95% CI)	1.91 [0.19, 19.63]
9 HCV recurrence	10	477	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.92, 1.15]
9.1 No antiproliferative agent	7	386	Risk Ratio (M-H, Fixed, 95% CI)	1.10 [0.98, 1.22]
9.2 Mycophenolate mofetil	2	76	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.55, 1.22]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
9.3 Azathioprine	1	15	Risk Ratio (M-H, Fixed, 95% CI)	0.23 [0.03, 1.52]
10 Renal insufficiency	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.93 [0.73, 1.19]
10.1 No antiproliferative agent	3	417	Risk Ratio (M-H, Fixed, 95% CI)	0.91 [0.72, 1.16]

Comparison 8.   Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression (best-worst analysis)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Mortality	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.80, 1.22]
1.1 Glucocorticosteroid avoidance	10	782	Risk Ratio (M-H, Fixed, 95% CI)	1.15 [0.87, 1.52]
1.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.60, 1.12]
2 Graft loss including death	11	1002	Risk Ratio (M-H, Fixed, 95% CI)	0.98 [0.78, 1.24]

2.1 Glucocorticosteroid avoidance	8	671	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.77, 1.39]
2.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	0.90 [0.61, 1.33]
3 Acute rejection	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.04 [0.85, 1.26]
3.1 Glucocorticosteroid avoidance	10	782	Risk Ratio (M-H, Fixed, 95% CI)	1.37 [1.04, 1.81]
3.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	0.78 [0.59, 1.02]
4 Infection	8	778	Risk Ratio (M-H, Fixed, 95% CI)	0.80 [0.67, 0.96]
4.1 Glucocorticosteroid avoidance	6	500	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.80, 1.15]
4.2 Glucocorticosteroid withdrawal	2	278	Risk Ratio (M-H, Fixed, 95% CI)	0.24 [0.12, 0.50]
5 Chronic rejection	9	974	Risk Ratio (M-H, Fixed, 95% CI)	0.59 [0.33, 1.05]
5.1 Glucocorticosteroid avoidance	6	586	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.32, 2.08]
5.2 Glucocorticosteroid withdrawal	3	388	Risk Ratio (M-H, Fixed, 95% CI)	0.48 [0.23, 1.02]
6 Glucocorticosteroid-resistant rejection	10	1020	Risk Ratio (M-H, Fixed, 95% CI)	1.00 [0.61, 1.65]
6.1 Glucocorticosteroid avoidance	7	689	Risk Ratio (M-H, Fixed, 95% CI)	1.88 [0.89, 3.98]
6.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	0.55 [0.27, 1.13]
7 Diabetes mellitus	12	1185	Risk Ratio (M-H, Fixed, 95% CI)	0.71 [0.58, 0.86]
7.1 Glucocorticosteroid avoidance	7	674	Risk Ratio (M-H, Fixed, 95% CI)	0.90 [0.70, 1.17]
7.2 Glucocorticosteroid withdrawal	5	511	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.39, 0.70]
8 CMV infection	7	786	Risk Ratio (M-H, Fixed, 95% CI)	0.57 [0.37, 0.87]
8.1 Glucocorticosteroid avoidance	5	502	Risk Ratio (M-H, Fixed, 95% CI)	0.76 [0.39, 1.49]
8.2 Glucocorticosteroid withdrawal	2	284	Risk Ratio (M-H, Fixed, 95% CI)	0.46 [0.27, 0.81]
9 Malignancy	3	528	Risk Ratio (M-H, Fixed, 95% CI)	0.21 [0.07, 0.61]
9.1 Glucocorticosteroid avoidance	2	354	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.13, 2.08]
9.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	0.08 [0.01, 0.57]
10 Post-transplant lymphoproliferative disorder	2	330	Risk Ratio (M-H, Fixed, 95% CI)	0.24 [0.07, 0.85]
10.1 Glucocorticosteroid avoidance	1	156	Risk Ratio (M-H, Fixed, 95% CI)	2.0 [0.19, 21.61]
10.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	0.09 [0.01, 0.67]
11 Hypertension	10	1098	Risk Ratio (M-H, Fixed, 95% CI)	0.70 [0.60, 0.82]
11.1 Glucocorticosteroid avoidance	6	634	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.66, 1.00]
11.2 Glucocorticosteroid withdrawal	4	464	Risk Ratio (M-H, Fixed, 95% CI)	0.59 [0.47, 0.76]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
12 Hyperlipidaemia	4	400	Risk Ratio (M-H, Fixed, 95% CI)	0.40 [0.21, 0.73]
12.1 Glucocorticosteroid avoidance	2	150	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.45, 2.52]
12.2 Glucocorticosteroid withdrawal	2	250	Risk Ratio (M-H, Fixed, 95% CI)	0.16 [0.06, 0.45]

Comparison 9. Glucocorticosteroid avoidance or withdrawal versus glucocorticosteroid-containing immunosuppression (worst-best analysis)

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Mortality	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.35 [1.10, 1.67]
1.1 Glucocorticosteroid avoidance	10	782	Risk Ratio (M-H, Fixed, 95% CI)	1.13 [0.86, 1.49]
1.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	1.71 [1.23, 2.38]
2 Graft loss including death	11	1002	Risk Ratio (M-H, Fixed, 95% CI)	1.38 [1.08, 1.74]
2.1 Glucocorticosteroid avoidance	8	671	Risk Ratio (M-H, Fixed, 95% CI)	1.05 [0.78, 1.41]
2.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	2.24 [1.47, 3.41]
3 Acute rejection	16	1347	Risk Ratio (M-H, Fixed, 95% CI)	1.53 [1.25, 1.88]
3.1 Glucocorticosteroid avoidance	10	782	Risk Ratio (M-H, Fixed, 95% CI)	1.38 [1.05, 1.83]
3.2 Glucocorticosteroid withdrawal	6	565	Risk Ratio (M-H, Fixed, 95% CI)	1.73 [1.29, 2.31]
4 Infection	8	778	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.87, 1.23]
4.1 Glucocorticosteroid avoidance	6	500	Risk Ratio (M-H, Fixed, 95% CI)	0.96 [0.80, 1.15]
4.2 Glucocorticosteroid withdrawal	2	278	Risk Ratio (M-H, Fixed, 95% CI)	1.50 [0.89, 2.50]
5 Chronic rejection	9	974	Risk Ratio (M-H, Fixed, 95% CI)	2.45 [1.40, 4.31]
5.1 Glucocorticosteroid avoidance	6	586	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.32, 2.08]
5.2 Glucocorticosteroid withdrawal	3	388	Risk Ratio (M-H, Fixed, 95% CI)	4.87 [2.16, 11.01]
6 Glucocorticosteroid-resistant rejection	10	1020	Risk Ratio (M-H, Fixed, 95% CI)	3.71 [2.07, 6.66]
6.1 Glucocorticosteroid avoidance	7	689	Risk Ratio (M-H, Fixed, 95% CI)	1.99 [0.95, 4.17]
6.2 Glucocorticosteroid withdrawal	3	331	Risk Ratio (M-H, Fixed, 95% CI)	8.63 [2.95, 25.28]
7 Diabetes mellitus	12	1185	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.79, 1.15]
7.1 Glucocorticosteroid avoidance	7	674	Risk Ratio (M-H, Fixed, 95% CI)	0.92 [0.71, 1.19]
7.2 Glucocorticosteroid withdrawal	5	511	Risk Ratio (M-H, Fixed, 95% CI)	1.00 [0.76, 1.32]

8 CMV infection	7	786	Risk Ratio (M-H, Fixed, 95% CI)	1.29 [0.87, 1.90]
8.1 Glucocorticosteroid avoidance	5	502	Risk Ratio (M-H, Fixed, 95% CI)	0.81 [0.41, 1.59]
8.2 Glucocorticosteroid withdrawal	2	284	Risk Ratio (M-H, Fixed, 95% CI)	1.70 [1.04, 2.78]
9 Malignancy	3	528	Risk Ratio (M-H, Fixed, 95% CI)	3.05 [1.38, 6.73]
9.1 Glucocorticosteroid avoidance	2	354	Risk Ratio (M-H, Fixed, 95% CI)	0.52 [0.13, 2.08]
9.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	10.71 [2.58, 44.45]
10 Post-transplant lymphoproliferative disorder	2	330	Risk Ratio (M-H, Fixed, 95% CI)	15.64 [3.08, 79.56]
10.1 Glucocorticosteroid avoidance	1	156	Risk Ratio (M-H, Fixed, 95% CI)	2.0 [0.19, 21.61]
10.2 Glucocorticosteroid withdrawal	1	174	Risk Ratio (M-H, Fixed, 95% CI)	43.89 [2.70, 714.49]
11 Renal insufficiency	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.75, 1.21]
11.1 Glucocorticosteroid avoidance	4	447	Risk Ratio (M-H, Fixed, 95% CI)	0.95 [0.75, 1.21]
12 Hypertension	10	1098	Risk Ratio (M-H, Fixed, 95% CI)	0.87 [0.75, 1.02]
12.1 Glucocorticosteroid avoidance	6	634	Risk Ratio (M-H, Fixed, 95% CI)	0.82 [0.67, 1.01]
12.2 Glucocorticosteroid withdrawal	4	464	Risk Ratio (M-H, Fixed, 95% CI)	0.94 [0.75, 1.18]
13 Hyperlipidaemia	4	400	Risk Ratio (M-H, Fixed, 95% CI)	1.92 [1.12, 3.28]
13.1 Glucocorticosteroid avoidance	2	150	Risk Ratio (M-H, Fixed, 95% CI)	1.18 [0.51, 2.73]
13.2 Glucocorticosteroid withdrawal	2	250	Risk Ratio (M-H, Fixed, 95% CI)	2.64 [1.28, 5.44]

W H A T ' S   N E W

Last assessed as up-to-date: 4 April 2018.

Date	Event	Description
16 November 2017	New search has been performed	Searches performed until May 2017. One new trial added, but data could only be incorporated into qualitative analysis
8 November 2017	New citation required but conclusions have not changed	Background updated. New references added. Searches re-executed. Long-term follow-up of one previously included trial now incorporated to meta-analysis. Three further meta-analyses addressing same or similar review question identified and incorporated to review discussion

CONTRIBUTIONS OF AUTHORS

CF prepared a draft protocol.

LP and CF wrote the final version of the protocol published previously.

SW, EH, and JP commented on the draft and approved of the final version of the protocol.

CF ran the searches.

CF contacted pharmaceutical companies and experts in the field.

CF, JP, SW, and EH selected studies for inclusion.

CF, JP, SW, and EH extracted data.

CF contacted authors to request additional information.

CF, JP, SW, and EH made assessments of bias.

CF entered trial data and performed analyses.

EH and CF worked on the code for empirical continuity correction for zero event trials and the linear regression test for funnel plot asymmetry.

LP completed the trial sequential analyses.

CF completed the results section and the discussion.

CF, LP, EH, JP, and SW wrote the author's conclusions.

LP, JP, EH, and SW made comments on the draft and approved the final version of the review.

DECLARATIONS OF INTEREST

Cameron Fairfield: none known.

Luit Penninga: none known.

James Powell: none known.

Ewen M Harrison: none known.

Stephen J Wigmore: none known.

SOURCES OF SUPPORT

Internal sources

- University of Edinburgh, College of Medicine and Veterinary Medicine, UK.
- Royal Infirmary Edinburgh, Hepatobiliary-Pancreatic Surgical Services and Edinburgh Transplant Unit, UK.
- Royal Infirmary Edinburgh, Clinical Surgery, UK.
- National University Hospital Rigshospitalet, Copenhagen, Denmark.

External sources

- No sources of support supplied

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

- Cholesterol and hypercholesterolaemia added to secondary outcomes.

- Renal function outcome modified.

- Number of sub-analyses reduced.

- Definition of the sub-analysis of 'co-interventions' changed.

- Per-treatment analyses added to exclusion criteria.

- Methods section modified to include "Assessment of heterogeneity", "Unit of analysis Issues" and "Measures of treatment effect"

INDEX TERMS

Medical Subject Headings (MeSH)

*Liver Transplantation [mortality]; *Withholding Treatment; Acute Disease; Calcineurin Inhibitors [therapeutic use]; Chronic Disease; Diabetes Mellitus [prevention & control]; Glucocorticoids [*administration & dosage; adverse effects]; Graft Rejection [drug therapy; mortality; *prevention & control]; Immunosuppression [*methods]; Immunosuppressive Agents [*administration & dosage]; Randomized Controlled Trials as Topic; Renal Insufficiency [etiology]
