## Statements of significance

This study places  $ERR\alpha$  at the interplay between the immune response and bone metastases of breast cancer, highlighting a potential target for intervention in advanced disease.

## Abstract (150 words)

Bone is the most common metastatic site for breast cancer. Although the estrogen-related receptor alpha ( $ERR\alpha$ ) has been implicated in breast cancer cell dissemination to the bone from the primary tumor, its role after tumor cell anchorage in the bone microenvironment remains elusive. Here, we reveal that  $ERR\alpha$  inhibits the progression of bone metastases of breast cancer cells by increasing the immune activity of the bone microenvironment. Overexpression of  $ERR\alpha$  in breast cancer bone metastases induced expression of chemokines CCL17 and CCL20 and repressed production of transforming growth factor beta 3 ( $TGF-\beta 3$ ). Subsequently,  $CD8^+$  T lymphocytes recruited to bone metastases escaped  $TGF-\beta$  signaling control and were endowed with exacerbated cytotoxic features, resulting in significant reduction in metastases. The clinical relevance of our findings in mice was confirmed in over 240 breast cancer patients. Thus, this study reveals that  $ERR\alpha$  regulates immune properties in the bone microenvironment that contributes to decreasing metastatic growth.

## Introduction

Bone metastases (BM) are a frequent complication of cancer, occurring in up to 70 percent of patients with advanced breast cancer (BCa), and are associated with both high morbidity and elevated mortality (1)(2)(3). The progression of BM relies on the ability of the malignant cell colonizing the bone and to modify bone micro-environment allowing the release of bone-stored factors including transforming growth factor (TGF- $\beta$ ), bone morphogenetic protein (BMP) or insulin growth factor (IGF), which in turn stimulate BM progression (2)(4). However treatments which mainly involved anti-resorptive agents of the bone failed to improve the overall survival of cancer patients even though it inhibited osteoclasts resorptive activity (3), implying that other mechanisms than the activation of osteoclasts by tumor cells are involved in modulating BM growth. The immune cells present in the bone, and particularly activated CD8<sup>+</sup> T lymphocytes can repress the progression of BCa osteolytic BM (5)(6)(7)(8). However, whether BM can influence the activation of immune cells present in the bone and by which mechanisms is totally unknown.

The estrogen-related receptor alpha (ERR $\alpha$ , or NR3B1 according to the Nuclear Receptors Nomenclature Committee, 1999) is over expressed in 55% of breast tumors (9)(10). Though ERR $\alpha$  shares structural similarities with the estrogen receptors  $\alpha/\beta$ , it does not bind estrogens and no natural ligand has yet been found (11), though several molecules can either increase or decrease ERR $\alpha$  activity, such as the inverse-agonists XCT790 or C29 (12)(13). ERR $\alpha$  is mainly involved in the adaptive bioenergetics response (11). In cancer, beside angiogenesis, ERR $\alpha$  is strongly linked to tumor cell-invasion (14)(15). Notably, ERR $\alpha$ -positive tumors are associated with more invasive BCa and a higher risk of recurrence (9)(14). The over-expression of ERR $\alpha$  in BCa promotes tumor growth in the mammary gland and BCa metastatic dissemination to the bone (16). However, the role of ERR $\alpha$  in BM outcome once they are anchorage in the bone microenvironment remains elusive.

In this study, using loss and gain of expression of  $ERR\alpha$ , as well as chemical inhibitors, we demonstrated that  $ERR\alpha$  enhanced the ability of BCa cell established in the bone to recruit activated  $CD8^+$  T cells to the bone. In addition,  $ERR\alpha$  expression on BCa cells repressed their ability to produce TGF- $\beta$ , a potent immune-suppressive cytokine. Subsequently, TGF- $\beta$  signaling was impaired in T cells infiltrating the bone, and  $CD8^+$  T cell cytotoxic function exacerbated leading to metastatic progression. Altogether, our work assigns a totally unexpected role to  $ERR\alpha$ , revealing that the expression of this orphan receptor on the BCa metastases promotes an efficient anti-tumor immune response once the tumor cells are settled in bone.

## Materials and Methods

### *Cell lines*

The mouse triple negative breast (TNBC) cancer cell line 4T1 (year 2012) (ATCC lot: 58603185-CRL-2539) and human luminal MCF7 (year 2012) (ATCC-HTB-22 Lot: 86012803) were obtained from the American Type Culture Collection. MDA-MB-231/BO2-FRT (BO2) BCa cells, a subpopulation of the human MDA-MB-231 BCa line (TNBC) was selected for their high efficiency to metastasize to bone (17). These cell line was tested for authentication by DNA fingerprinting using short repeat (STR) method in 2014. TNBC cell lines and MCF7 were cultured in DMEM or RPMI-1640 (Life-Technologies) medium, respectively, supplemented with 10% fetal bovine serum (FBS, Perbio) and 1% penicillin/streptomycin (Invitrogen) at 37°C in a 5% CO<sub>2</sub> incubator. Cells lines were tested for mycoplasma regularly. Mouse and human *ESRRA* cDNA ( $ERR\alpha$ ) and the dominant-negative co-activator domain AF2 (AF2) mutant were described previously (16)(18). Briefly, pSR $\alpha$ - $ERR\alpha$ WT and pEcmv- $ERR\alpha$ AF2 or respective empty vectors (CT) constructs were transfected into parental 4T1 cells and cultured for 4 weeks in puromycin (2  $\mu$ g/mL) (Life-Technologies). Three independent clones were obtained from pSR $\alpha$ - $ERR\alpha$ WT transfection (4T1- $ERR\alpha$ ) and from pEcmv- $ERR\alpha$ AF2 transfection (4T1-

ERR $\alpha$ AF2). Two independent clones were obtained from empty vectors transfection respectively pSR $\alpha$ -4T1-CT (4T1-CT) and pEcmv-4T1-CT (4T1-CTaf2). For MCF7 clones, a mix containing 1.5 $\mu$ g Retroviral pLPCX-Human-ERR $\alpha$ WT, pLPCX-HumanERR $\alpha$ AF2 or empty vector and 0.5 $\mu$ g pCMV-VSV-G envelope vector (Cell-Biolabs) were used previously (16). 4T1-ERR $\alpha$  and 4T1-ERR $\alpha$ AF2 (pool of 3 clones each) cells were treated for 24 hours with the ERR $\alpha$  inverse-agonists XCT790 (Sigma) or C29 (AGVdiscovery, France) at 1 $\mu$ M and 5 $\mu$ M, respectively, as described (13) (16) (19). DMSO was used as a vehicle (Veh).

### *Animal studies*

6-week-old BALB/c female mice were purchased from Janvier (France) and housed in a SPF facility (ALECS platform (Faculté de Médecine Laennec, Lyon, France). BM experiments were performed by inoculating intra-arterially either 4T1-CT (pool of 2 clones) in parallel with 4T1-ERR $\alpha$  (pool of 3 clones), or 4T1-CT(af2) (pool of 2 clones) in parallel with 4T1-ERR $\alpha$ AF2 (pool of 3 clones) cell lines ( $5 \times 10^5$  cells in 100  $\mu$ L of PBS). Radiographs (LifeRay HM Plus, Ferrania) of animals were taken at 15 days after inoculation using X-ray (MX-20; Faxitron X-ray Corporation). The extent of bone destruction for each animal was expressed in mm<sup>2</sup>. Animals were sacrificed and hind limbs were then collected for histology and histomorphometric analysis. Tibiae were scanned using microcomputed tomography (Skyscan1076, Skyscan, Belgium) with an 8.8 voxel size and an X-ray tube (50 kV; 80 mA) with 0.5  $\mu$ m aluminum filter and three-dimensional reconstructions were performed with a dedicated visualization software (NRecon&CTVox, and Skyscan) (18). Bone Volume/Tissue Volume: (%BV/TV) were carried out with CTAn (version 1.9, Skyscan) and CTVol (version 2.0, Skyscan) software. Dissected bones were then processed for histological (Goldner's Trichrome solution staining) and histomorphometric analyses (tumor burden-to-soft tissue volume (%TB/STV)) (18). Depletion of CD8<sup>+</sup> T cells was performed by intra-peritoneal injection of anti-CD8 $\beta$  (BioXCell, clone Lyt3.2;

BE0223). 387.5  $\mu\text{g}$  per mouse were injected 4 times every two days, from day 10 after metastasis injection *i.e* when osteolytic lesions start to be detectable.

#### *Ethics statement*

Mice were handled according to the French Ministerial Decree No.87-848 of 19 October 1987. Experimental protocols were approved by the Institutional Animal Care and Use Committee at the Université-Lyon1 (France) (ethic committee CEEA-55 Comité d’Ethique en Expérimentation Animale-DR2014-44-DR2015-28).

#### *Human sample meta-genomic analysis*

Correlation analysis were performed using published datasets downloaded from the Gene-Expression-Omnibus including primary tumor, no-metastases, Visceral+bone or only BM (GSE12276-GSE2034-GSE2603) (n=248) (20)(21)(22). Z-scores were calculated on normalized data of each dataset by subtracting the population mean from individual expression values for each gene and then dividing the difference by the population standard deviation.

#### *Sign arrays*

The expression levels of several chemokines known to influence T cell chemo-attraction were obtained by qPCR Sign Arrays (Cytokines Array and Inflammation Array). Indeed, two qPCR Sign Arrays: Cytokines and Inflammation Arrays (AnyGenes, CT1M1-IFM1)(CliniSciences) were used to quantify expression of cytokines, chemokines and growth factors. Total RNA was extracted from 4T1-CT and 4T1-ERR $\alpha$  cells and 2  $\mu\text{g}$  were reverse-transcribed as previously described (16). Real-Time PCR was performed according to the manufacturer’s instructions. Two heat maps were generated using the heatmap.2 function in the gplots library of R (version 3.5.1). Only regulations that were reproducible between the two arrays are presented.

#### *Protein-protein interaction network reconstruction and analysis.*

The protein-protein interaction network with BIOGRID (release 3.4.160) from *Homo sapiens* with PSICQUIC (Proteomics-Standard-Initiative-Common-QUery-InterfaCe) retrieval (10242018) and Cytoscape environment was used (16). A BIOGRID (<https://thebiogrid.org/>)-based custom approach was used to define a protein interactome of the following proteins: ESRRA-CCL17-CCL20-OPG-NRIP1-SRC1-SRC2-SRC3-PGC1A-PGC1B-CCR4 and CCR6. The resulting interactome encompasses 911 proteins (hereby defined as “Extended Network of ESRRA, CCL17, CCL20”) (reachable on Ndex webserver [here](#)) (Supplementary Fig.S1). To determine the connectors between CCL17, CCL20 and ESRRA, a custom approach combining shortest path and connectivity degree analysis was applied to determine a “Minimal Network of ESRRA, CCL17, CCL20” (reachable on Ndex webserver [here](#)) (containing 101 proteins) acknowledging connections that may support ESRRA signaling (Supplementary Fig. S2) (16). We overlaid and extracted information from the Gene-Ontology-consortium to pinpoint proteins that are already known to be involved in the immune system process, as well as T and B cell homeostasis (GO-IDs: 0002376, 0043029, 0001782) to create “Minimal Network specific to immune response to tumor” (containing 52 proteins). To determine the connectors between ESRRA and CCL17, ESRRA and CCL20, a shortest path was applied to the “Minimal Network of ESRRA, CCL17 and CCL20” (16)(23)(24).

### *Ex vivo cell preparation*

For hind limbs, muscles were removed and bones were sliced, then incubated at 37°C with a 1/10 solution of collagenase hyaluronidase (Stem cell) for 2 hours. Bones were then mechanically disrupted with a syringe plunger, filtered and cells were collected. For lung metastases (LM), lungs were crushed with a syringe plunger on a filter (100 µm) (BD Bioscience) and cells were collected. Cells released from lungs and bones were incubated at 37°C in the presence of DMEM (Life Technologies) supplemented with 10% (v/v) fetal bovine serum (Perbio/Thermo Scientific)

and 6-thioguanine (Sigma A4882) (10  $\mu\text{g}/\text{mL}$ ) for 2 weeks. The cells were then counted after being stained using Crystal Violet (RAL diagnostic 317980).

### *Flow Cytometry*

Cells from spleen and lungs, obtained after mechanical disruption, and flushed bone marrow cells were pre-incubated with anti-CD16/32 (93 clone, Biolegend) and stained for surface marker for 30 minutes at 4°C with the following antibodies: anti-CD45 (30-F11 clone, BD or eBiosciences), anti-CD3e (145-2C11 clone, BD), anti-CD4 (GK1.5 clone, BD), anti-CD8 (53-6.7 clone, BD or eBiosciences), anti-CD19 (1D3 clone, BD), anti-CD11b (M1/70 clone, eBiosciences), anti-CD11c (N418 clone, eBiosciences), anti-CCR4 (2G12 clone Biolegend) anti-CCR6 (29-2217clone Biolegend), anti-Ly6C (AL21 clone, BD), anti-Ly6G (1A8 clone, BD), anti-F4/80 (BM8 clone, Biolegend), anti-CD107a (LAMP-1)(1D4B clone, BD), anti-FasL (MFL3 clone, eBiosciences). For cytokine production, cells were first incubated for 4 hours with PMA (P1585-1MG, Sigma), Ionomycin (I0634-1MG, Sigma) and Brefeldin A (00-4506-51, Life Technologies). Intracellular staining was performed with the Transcription Factor Staining Buffer Set (00-5523-00, eBiosciences), according to manufacturer's recommendations. The following antibodies were used: anti-Foxp3 (R16-715 clone, BD), anti-IFN- $\gamma$  (XMG1.2 clone, BD), anti-GzA (GzA-3G8.5 clone, eBiosciences), anti-GzB (GB11 clone, Invitrogen), anti-Ki67 (11F6 clone Biolegend), anti-pSMAD2/3 (D27F4 clone, Cell Signalling) coupled with anti-rabbit A488. CD8<sup>+</sup> T cell depletion was checked by flow cytometry on metastatic bone marrow and spleen using anti-CD8 $\alpha$  (53-6.7 eBiosciences). Data were acquired on a LSR-II (BD Biosciences) and analyzed with the FlowJo software version X.

### *Determination of ERRA binding sites*

The analysis of  $ERR\alpha$  binding sites on TCA AGGTCA promoter regions was performed using the GTRD (“Gene Transcription Regulation Database”) that includes ChIP-seq data (<http://gtrd.biouml.org/>)(25).

#### *Chromatine immunoprecipitation (ChIP)*

ChIP assays were performed as previously described (16) from MDA-MB231-B02-CT and - $ERR\alpha$  cells (18) using either a monoclonal rabbit anti- $ERR\alpha$ (13826)(Cell-Signaling) or a control rabbit IgG(2729) antibody (Cell-Signaling). The immune-precipitated genomic DNA was purified using NucleoSpin Clean-up columns (Macherey-Nagel,Germany) and analyzed by qPCR. Quantification of ChIP enrichment was calculated relative to input values. Distal and proximal elements of  $ERR\alpha$  gene were used as negative and positive controls respectively (26).

#### *Histology-Immunocytochemistry*

Tibia bearing metastases as well as lungs were fixed in 4% PFA (paraformaldehyde) (Antigenfix Diapath P0014), embedded in paraffin (Histowax Histolab 00403) then cut (5 $\mu$ m sections) on a microtome (Microm HM 350S). Immunocytochemical analyses were performed by incubating tissue sections overnight with goat polyclonal antibody  $ERR\alpha$  (V-19, Santa Cruz) (1/40), rabbit polyclonal anti-human/mouse  $CCL17$  (PA5-34515, ThermoFisher) (1/100), rabbit polyclonal anti-mouse  $CCL20$  (ab139585, Abcam) (1/100), rabbit polyclonal anti-human/mouse activated  $TGF-\beta3$  (ab15537, Abcam) (1/100). Sections were then incubated with HRP-conjugated anti-mouse (K4000, Dako) and anti-rabbit (K4002, Dako) according to the manufacturer’s recommendations or anti-goat (sc2020, Santa Cruz)(1/300) antibodies for 1 hour and were detected using 3,3'-diaminobenzidine (K3467, Dako) according to the manufacturer’s instructions. Counterstaining was performed using Mayer’s hematoxylin (Merck) according the supplier’s protocol. Lungs sections were made at three different depths for each mouse and stained with H&E. Metastasis counting was performed in double blind.

### *TUNEL assay*

Bone sections were deparaffinized and rehydrated followed by permeabilization with 0.2% triton (T9284, Sigma) and digestion with proteinase K (1 $\mu$ g/mL) (K182001, ThermoFisher). For positive control, sections were incubated with DNase I at 1mg/mL (Sigma, 11284932001). Sections were then incubated with biotin-16-dUTP (Sigma, 11093070910) and TUNEL enzyme (Sigma, 11767305001) in deoxynucleotidyltransferase buffer (Tris-HCl 125mM (Euromedex, EU0011), sodium cacodylate 200mM (Sigma, C0250), BSA 6mM (Sigma, A7906), CoCl<sub>2</sub> 1mM (Sigma, 15862-1ml-F)) at 37°C for 60 minutes in a humid atmosphere. Sections were washed in stop buffer (300mM NaCl (Sigma, S3014), 30mM NaC<sub>6</sub>H<sub>5</sub>O<sub>7</sub>-sodium citrate (Sigma, 71406)) and blocked with 2% BSA (Sigma, A7906). Sections were then labelled with streptavidin-phycoerythrin (PE) (eBiosciences, 12-4317-87) and DAPI (Euromedex, 1050-A) and mounted with Fluoromount (Sigma, F4680-25ml) (upright microscope zeiss axioimager (sip 60549)).

### *Real time RT-PCR*

Total RNAs from three independent batches of each clone of 4T1, MCF7 and B02 cell (CT, ERR $\alpha$  and ERR $\alpha$ AF2) were extracted with Trizol-reagent (Life-Technologies) and 2 $\mu$ g were reverse-transcribed using qScript<sup>TM</sup> cDNA SuperMix (Quanta-Biosciences). Real-time PCR was performed on a Mastercycler-ep-Realplex (Eppendorf) with primers specific to human and mouse genes (Supplementary Table S1) using Quantifast-SYBR-Green (Life-Technologies) according to the manufacturer's instructions. The ribosomal protein *RPL32* (*L32*) gene was used as a housekeeping gene for quantification and relative results expressed as fold differences equal to  $2^{-\Delta\Delta Ct}$ .

### *Statistical analyses*

Data were analyzed statistically using either the non-parametric Mann-Whitney U test or unpaired t-test for *in vivo* studies (n = 10 mice for each group (bioStaTGV), unblinded studies). *In vivo* data

on bone were confirmed (n = 3) on smaller groups (n = 4). *In vitro* assays were repeated at least twice and performed on triplicate samples. Data were analyzed using ANOVA and paired Student t-test to assess the differences between groups. All data are presented as means  $\pm$  SEM with similar variances between groups. Correlation scores for meta-analysis were calculated using the Pearson-correlation-coefficient. Statistical significance was determined by GraphPad Prism v5.02 using the two-sided Student t-test. All statistical analyses were performed using the GraphPad Prism software (San Diego, USA). P-values less than 0.05 were considered statistically significant.

## Results

### *ERR $\alpha$ expression in BCa cells inhibits metastases growth in bones*

In order to assess the role of ERR $\alpha$  in BCa cells after tumor cell-anchorage in the bone microenvironment, BALB/c mice were intra-arterially injected with first a pool of three independent 4T1 tumor cell clones over-expressing-ERR $\alpha$  (4T1-ERR $\alpha$ ), and a pool of two 4T1 tumor cell clones transfected with empty vector controls (4T1-CT) (16). Remarkably, fifteen days later, radiographic analysis revealed that animals bearing 4T1-ERR $\alpha$  tumors had osteolytic lesions that were 70% smaller than those of mice bearing 4T1-CT tumors ( $9.39 \pm 2.6$  vs  $3.08 \pm 1.45$  mm<sup>2</sup>) (**Fig. 1A,B**). The inhibitory effect of ERR $\alpha$  on BCa cell growth was associated with mild bone destruction (**Fig. 1C-E**). Histological and histomorphometric analyses also demonstrated the limitation of BM progression when BCa cells over-expressed ERR $\alpha$  (**Fig. 1F,G**). In clear contrast, when clones expressing a dominant-negative form (4T1-ERR $\alpha$ AF2) with their respective controls clones (4T1-CTaf2) were injected later, we found a 60% increase in osteolytic lesions in animals bearing ERR $\alpha$ AF2 tumors compared to control (4T1-CTaf2) mice ( $3.82 \pm 1.99$  vs  $9.27 \pm 2.064$  mm<sup>2</sup>) leading to their earlier sacrifice, prior 4T1-CT(af2) BM reach the percentage of osteolysis observed in 4T1-CT (**Fig. 1H,I**). Concomitantly, increased bone destruction and tumor burden

was observed (**Fig. 1J-N**). Given that 4T1 cells also colonize the lung (16), we analyzed the effects of  $ERR\alpha$  expression on the development of LM. As opposed to the bone, both numbers of LM and numbers of BCa colonies extracted from the lungs were independent of the expression levels of  $ERR\alpha$  in 4T1 cells (**Fig. 2A-F**). Of note, the  $ERR\alpha$  over-expression in LM was observed in animals bearing 4T1- $ERR\alpha$  tumors compared to control groups (**Fig. 2G**). Taken together, this first set of data reveals that the over-expression of  $ERR\alpha$  in BCa cells prevents their growth in the bone, and suggests that  $ERR\alpha$  expression in BCa may affect the bone microenvironment to prevent BM progression.

#### *ERR $\alpha$ expression in BCa cells increases T cell anti-tumor response in the bone*

Given the importance of the immune response in the control of tumor growth, in particular metastases (5)(6)(7)(8), we next analyzed the effects of the expression of  $ERR\alpha$  by BCa cells on the bone immune system. It is worth noting that no significant effect was observed on innate cells including dendritic cells, macrophages, with the exception of slight decrease in neutrophils (15%) in the bone colonized by 4T1- $ERR\alpha$  compared to 4T1-CT cells (Supplementary Fig. S3A-C). However, we found that metastatic legs of animals bearing 4T1- $ERR\alpha$  tumors contained 5 times more T cells than those colonized with 4T1-CT cells (**Fig. 3A**). Moreover, in line with the larger 4T1-CT BM observed (**Fig. 1**), which developed at the expense of the bone marrow that is largely depicted to sustain all stages of B cell medullary development (7)(8), the CD19<sup>+</sup> compartment was 4-5 times lower in mice bearing 4T1-CT BM compared to 4T1- $ERR\alpha$  BM (**Fig. 3A**). Of note, T cell enrichment was neither observed in the lungs where 4T1- $ERR\alpha$  cells were also anchored (**Fig. 3B**), nor in the none invaded lymphoid organs such as the spleen (Supplementary Fig. S3 D,E), implying that the expression of  $ERR\alpha$  in BCa cells affected the T cell homeostasis after their anchorage in the bone. Interestingly, the increase in T cell proportion after 4T1- $ERR\alpha$  cell bone settlement was largely restricted to the CD8<sup>+</sup>T lymphocyte compartment, with a 3.5-fold increase

in their number and percentage in bones bearing 4T1-ERR $\alpha$  tumors compared to bone colonized with 4T1-CT cells (**Fig. 3A**), whereas the proportion of CD4<sup>+</sup>T cells in the bone, including that of Foxp3<sup>+</sup> regulatory T (Treg) cells was unaffected (Supplementary Fig. S3C).

In order to further characterize the CD8<sup>+</sup> T cells over-represented in the bone after 4T1-ERR $\alpha$  cell colonization, we then analyzed their ability to produce cytotoxic molecules and cytokines. Strikingly, in bone colonized with 4T1-ERR $\alpha$  cells, we found that CD8<sup>+</sup> T cells expressed higher levels of FasL, Granzyme (Granz) A and B, in association with LAMP1 at their cell surface as well as IFN- $\gamma$  whereas these molecules were barely detectable in CD8<sup>+</sup> T cells from bones bearing 4T1-CT cells (**Fig. 3C-E**). In total agreement with this exacerbated cytotoxic program of CD8<sup>+</sup> T in the presence of 4T1-ERR $\alpha$  BCa cells in the bone, we found that a large fraction of 4T1-ERR $\alpha$  BM underwent apoptosis compared to 4T1-CT cells (**Fig. 3F,G**). No exacerbated sign of cytotoxic activity was observed in the non-invaded spleen or in the metastatic lungs of mice bearing 4T1-ERR $\alpha$  cells (Supplementary Fig. S4A). Importantly, the depletion of CD8<sup>+</sup> T cells was sufficient (**Fig. 4A**) to increase 4T1-ERR $\alpha$  BM progression (**Fig. 4 B-E**). This set of data suggests that the expression of ERR $\alpha$  in BCa cells influences the CD8<sup>+</sup> T cell homeostasis and increases their anti-tumor cytotoxic program in the bone allowing the control of the tumor progression.

#### *ERR $\alpha$ expression leads to high levels of CCL17 and CCL20 production in BCa cells*

The aforementioned data strongly suggest that the expression of ERR $\alpha$  by BCa cells influences the bone microenvironment to promote an efficient anti-tumor response. Interestingly, we failed to find any difference in Ki67 staining between CD8<sup>+</sup>T cells evolving with either 4T1-CT or 4T1-ERR $\alpha$ BM (Supplementary Fig. S4B), suggesting that ERR $\alpha$  expression affected T cell-recruitment to the bone rather than their proliferation in the bone. In order to address this hypothesis, we monitored the expression levels of several chemokines known to influence T cell

chemo-attraction and found a 2- and 3-fold up-regulation of *Ccl17* and *Ccl20* in 4T1-ERR $\alpha$  cells, respectively (**Fig. 5A,B**, Supplementary Fig. S5A, Table S2). C29 or XCT-790 were sufficient to inhibit the over-expression of both *Ccl17* and *Ccl20*, while no effect was observed in 4T1-ERR $\alpha$ AF2 cells ruling out any off-target effects (**Fig. 5C-D**; Supplementary Fig. S5B-C) (27), arguing in favour of a direct role for ERR $\alpha$  in the control of the expression of these two chemokines (13). Of note, the ability of ERR $\alpha$  to up-regulate *Ccl17* and *Ccl20* was also observed in other BCa cells including MCF7 and MDA-MB-231-B02 cells (Supplementary Fig. S5D-E) (16)(18). Interestingly, the up-regulation of CCL17 and CCL20, at both gene and protein levels due to ERR $\alpha$  over-expression was sustained in 4T1-ERR $\alpha$  BM (**Fig. 5E,F**) but lost in LM (Supplementary Fig. S5F). This data was reinforced following the analysis of ChIP-seq data revealing binding site for ERR $\alpha$  in the promoter of *Ccl17* and in *Ccl20* (Supplementary Fig.S6A-D).

Given that CCL17 and CCL20 were reported to attract the fraction of activated CD8<sup>+</sup> T cells expressing CCR4 and CCR6 (28), we next monitored the expression of both chemokine receptors on CD8<sup>+</sup> T cells from the bone of animals bearing BM. In total agreement with the ability of 4T1-ERR $\alpha$  cells to sustain their production of CCL17 and CCL20 in the bone, and the activated phenotype of CD8<sup>+</sup> T cells (**Fig. 3**), we found that, in bone colonized by 4T1-ERR $\alpha$ , a large fraction of CD8<sup>+</sup> T cells expressed either CCR4 or CCR6 or both (**Fig. 5G**). Thus, BCa cells over-expressing ERR $\alpha$  are endowed with a unique ability to produce high amounts of CCL17 and CCL20 and efficiently recruit activated CD8<sup>+</sup> T cells to the bone.

*ERR $\alpha$  expression in BCa cells reduces their TGF- $\beta$ 3 production and decreases TGF- $\beta$  signaling in BM*

Since the cytotoxic program of CD8<sup>+</sup>T cells was largely exacerbated in legs bearing 4T1-ERR $\alpha$  cells, we next assessed the mechanisms by which ERR $\alpha$  over-expression in BCa cells increased their cytotoxic function in the bone. To this end, we further investigated the connection

between CCL17-CCL20 and *ERRα* (*ESRRA*) by choosing a global approach combining bioinformatic analyses of protein interaction networks and transcriptional regulator databases (Supplementary Fig. S1:[extended network](#) -S2:[minimal network](#)) (29). We created the “Minimal Network specific to immune response to tumor” (containing 52 proteins) (**Fig. 6A**) and by shortest path analysis, we then identified two new *ESRRA*-CCL17 or *ESRRA*-CCL20-associated regulators: VCAM and TGF-β3 (**Fig. 6B,C**). We and others reported that *TGF-β* signalling in T cells inhibits the cytotoxic differentiation program of CD8<sup>+</sup> T cells both in humans and mice (30)(31), we thus focused on this cytokine. The analysis of *Tgf-β3* expression revealed a 70% decrease in 4T1-*ERRα* compared to 4T1-CT cells (**Fig. 6D**). *Ex vivo* bone cultures confirmed that *ERRα* up-regulation in BCa cells negatively regulates *Tgf-β3* expression with a 55% decrease compared to control BCa BM (**Fig. 6E**). Strikingly, immunohistological staining revealed that the production of TGF-β3 was largely decreased in BCa BM over-expressing *ERRα* (**Fig. 6F**). In agreement with the decrease of *Tgf-β3* expression in 4T1-*ERRα*, we observed an increase in TGF-β3 levels in 4T1-*ERRα*AF2 BM (**Fig. 6D**) and a 5-fold increase in *Tgf-β3* expression after treatment of 4T1-*ERRα* cells with the inverse agonist XCT-790 (**Fig. 6G**). Similar results were observed in MCF7 and MDA-MB-231-B02 human cell lines (**Fig. 6H**), ruling out an effect restricted to mouse 4T1 cells. Altogether these results reveal that the over-expression of *ERRα* represses the expression of TGF-β3 in BCa and could thus prevent the BCa BM from creating an immunosuppressive microenvironment provided by TGF-β signal activation in immune cells.

In order to unconditionally confirm that CD8<sup>+</sup>T cell evolving in 4T1-*ERRα* colonized bone escape TGF-β signaling control, we next analyzed CD8<sup>+</sup>T cells from metastatic legs for the phosphorylation of SMAD2/3 proteins which translates specifically the TGF-β signaling activation (32). Clearly, SMAD2/3 phosphorylation was 2-3 times lower compared to that of CD8<sup>+</sup> T cells from 4T1-CT metastatic legs (**Fig. 6I**). Thus, in addition to increasing CD8<sup>+</sup>T cell

recruitment to the bone,  $ERR\alpha$  over-expression in BCa cells impairs their ability to produce high amounts of TGF- $\beta$ 3, decreasing TGF- $\beta$  signaling in CD8<sup>+</sup>T cells, a key repressor of their cytotoxic activity and capacity to eliminate cancer cells.

*Over-expression of ESRRA (Err $\alpha$ ) in patient tumours is associated with high levels of CCL17 CCL20 and low levels of TGF- $\beta$ 3 expression*

Finally, we addressed the relevance of our data obtained in mice to the human pathology. We performed a meta-analysis on 248 patients including luminal and triple-negative breast tumors (TNBC) split into four groups: all tumors (n = 248), patients without metastases (No Mets, n = 121), patients that had visceral and bone metastases (Visceral+Bone metastases, n = 53) and patients that had only bone metastases (Bone Only, n = 74). As in mice, the *ESRRA (Err $\alpha$ )* expression was positively correlated with that of *CCL17* and *CCL20* and inversely proportional to that of *TGF- $\beta$ 3* in patients with metastases restricted to the bone (Bone Only) with luminal and TNBC tumors (**Table 1A,B**). Correlations were also identified in no-Mets, All, and Visceral +Bone groups of luminal or TNBC patients (**Table 1A,B**). In addition  $ERR\alpha$  expression was not associated with LM in two cohorts of BCa patients (16). Thus, this set of data from human sample analyses strongly suggests that, similarly to mice, the over-expression of *ERR $\alpha$*  in human BCa cells allows them to create an immune-efficient environment in the bone by increasing the production of chemokines capable of attracting activated T cells to the bone and decreasing the production of TGF- $\beta$  essential for repressing the cytotoxic activity of T cells.

## **Discussion**

Cancer cells adapt to the microenvironment, shaped by their own doing, which in turn influence their fate. This interplay is particularly important for cells forming metastases, which leave their primary microenvironment to settled in a new, second one. Here, we revealed that the level of

ERR $\alpha$  expression on BCa metastases promotes their ability to condition an efficient anti-tumor CD8<sup>+</sup> T cell response selectively in the bone.

CD8<sup>+</sup> T cells have been described as critical inhibitors of bone metastases. Indeed, in mice, the alteration of CD8<sup>+</sup> T cell development after metastases implantation in the bone, or the deprivation of CD8<sup>+</sup> T cells, were reported to increase tumor growth (5)(6). Osteoclasts have been depicted to secrete chemokines that can attract CD8<sup>+</sup>T cells (33). However, the regulation of the BM burden by CD8<sup>+</sup> T cells seems totally independent of the osteoclast activity (6). Our study reveals that the cancer cells *per se* can influence both the recruitment and the cytotoxic activity of the CD8<sup>+</sup> T cells in the bone. Moreover, the ability of the BCa metastases to condition the immune response in the bone can be in part orchestrated by the levels of expression ERR $\alpha$  on the BCa and potentially to the sensitivity of metastases to the ERR $\alpha$  ligand(s). The selective effects of ERR $\alpha$  expression in BCa on the tumor burden of BM and anti-tumor response in the bone strongly suggest that unlike the lung, the bone could constitute a microenvironment with high levels of the ERR $\alpha$  ligand(s) that so far remain uncharacterized. Another alternative is that in the lung, but not the bone could be highly enriched in inhibitors of ERR $\alpha$  signaling or negative regulators of ERR $\alpha$  expression that remain to be identified. Thus, the ability of the metastases to induce or not a potent immune response maybe dictated by both the tumor *per se* and the microenvironment where it is anchored. In the case of BCa cells, we propose to place ERR $\alpha$  at the core of this interplay between metastases and their new microenvironment

In addition to increasing the recruitment of activated CD8<sup>+</sup> T cells to the bone, the over-expression of ERR $\alpha$  on BCa cells also decreased their ability to produce high amounts of TGF- $\beta$ 3. Depletion experiments confirmed that CD8<sup>+</sup> T cells are key anti tumor immune cells whose activation and recruitment are controlled by the levels of ERR $\alpha$  expression on BM. All forms of TGF- $\beta$  have been reported as potent immune-regulators and share a common receptor (34). While TGF- $\beta$ 1 is predominant in the immune system, TGF- $\beta$ 3 is mainly produced by muscles, bones

but also by various cancer cells (35). The repression of TGF- $\beta$ 3 production in ERR $\alpha$  BCa cells, subsequently affects TGF- $\beta$  signaling in CD8<sup>+</sup> T cells present in the bone. TGF- $\beta$  signaling represses the expression of numerous transcription factors associated with cytotoxicity, as well as T-Bet a key inducer of IFN- $\gamma$  (36). Therefore, over-expressed ERR $\alpha$  BCa cells that settle in the bone are unable to sustain an immunosuppressive microenvironment based on high levels of TGF- $\beta$  signaling in T cells and repression of cytotoxic program and IFN- $\gamma$  production. Interestingly IFN- $\gamma$  also contributes to the suppression of BM. Indeed, IFN- $\gamma$  has been reported to reduce both RANKL expression and osteoclast formation, counterbalancing the aberrant bone resorption which facilitates tumor growth (37). Concomitantly, inhibition of bone resorption also leads to the decrease in TGF- $\beta$  release from the bone matrix (4), thus potentially contributing to amplifying the activation of T cells including their production of IFN- $\gamma$ .

It is likely that effector CD8<sup>+</sup>T cells that reach the BM have previously been primed in the draining lymph nodes or by the spleen-presenting antigens from the primary tumor and/or the metastases. As in the primary tumor, the activated CD8<sup>+</sup>T cell population in contact with the BM is actually heterogeneous and composed of cells recently activated and activated memory cells. Interestingly, in both mice and humans, the fraction of CD8<sup>+</sup>T cells that expresses CCR6 and CCR4 has been depicted to rapidly mount an efficient response, corresponding to activated /memory T cells (28). Once implanted in the bone, we found that the BCa over-expressing ERR $\alpha$  have unique ability to sustain high expression of CCL17 and CCL20 and low expression of TGF- $\beta$ 3, thus attracting the activated/memory CD8<sup>+</sup>T cells whose their anti-tumor cytotoxic function is magnified by the lack of repression by TGF- $\beta$  signaling.

In conclusion, this study assigns an unsuspected role for ERR $\alpha$  expression in BCa on the bone immune system that conditions the BM growth outcome, providing the mechanistic basis for understanding how ERR $\alpha$  expression in BCa can impact the bone microenvironment and reduce BM growth. ERR $\alpha$  seems to appear at the core of this interplay between BCa metastases and their

new environment, integrating signals from the microenvironment to develop an efficient anti-tumor response. Therefore, we propose to consider  $ERR\alpha$  expression on BCa, as a biomarker predictive of BM response to immunotherapies and /or as a good prognosis marker in BM progression once established, opening the path towards to the clinical use of  $ERR\alpha$  agonist to relieve patients with  $ERR\alpha$  positive BM after primary tumor resection.

## Table and Figure legends

### Fig. 1: Inhibition of BM development by $ERR\alpha$ overexpression in BCa.

(A-N), 4T1-CT, 4T1- $ERR\alpha$  or 4T1-CT(af2) and 4T1- $ERR\alpha$ AF2 cells were inoculated into BALB/c mice. 13-15 days post-inoculation, osteolytic lesions were analyzed. (A) Representative radiography. The osteolytic regions are delimited by dash lines. (B) Graphs illustrate the mean size ( $\text{mm}^2$ )  $\pm$  SEM of osteolytic lesions (n=10 mice per group, Mann-Whitney, osteolysis:  $P < 0.0001$ : 4T1- $ERR\alpha$  versus CT). (C, D) Three-dimensional microCT reconstruction representation of tibiae in sagittal sections (C) and cross sections (D) following the cutting of the bone along the plane illustrated by the dashed lines in C. (E) Graphs illustrate the mean of the % of Bone Volume/Tissues Volume  $\pm$  SEM (n=10, Mann-Whitney, BV/TV:  $P < 0.0001$  for 4T1- $ERR\alpha$  versus CT). (F) Histological images of bone sections after Goldner's Trichrome staining. Tumors are delimited by dash lines and \* indicate the bone marrow. (G) Graphs illustrate the mean of % of Tumor Burden /Soft Tissues Volume  $\pm$  SEM (n=10, Mann-Whitney, TB/STV:  $P < 0.0001$  for 4T1- $ERR\alpha$  versus CT). (H-N) Respective representation and quantification of clones expressing a dominant-negative form (4T1- $ERR\alpha$ AF2) with their controls clones (4T1-CTaf2): osteolytic lesions (n=9, Mann-Whitney, osteolysis:  $P < 0.0006$ :  $ERR\alpha$ AF2 versus CT (af2)) (H, I), % of Bone Volume/Tissues Volume  $\pm$  SEM (n=9, Mann-Whitney, BV/TV:  $P < 0.0006$  for 4T1- $ERR\alpha$ AF2 versus CT(af2)) (J-L) and % of Tumor Burden /Soft Tissues Volume  $\pm$  SEM (n=9, Mann-Whitney, TB/STV:  $P < 0.0002$  for 4T1- $ERR\alpha$ AF2 versus CT(af2)) (M, N).

### Fig. 2: Overexpression of $ERR\alpha$ in BCa cells has no impact on lung metastases development.

(A) Histological analysis assessment of lung of mice 15 days post-cell injection after H&E coloration. Metastasis are marked with \* (B) Graph illustrate the numbers of LM counted on 3 representative sections at different levels of deepness (n=6). (C-F) Lungs from the same mice used to quantify BM (Fig.1) were crushed and cells released were cultured for 2 weeks. (C and E) are

representative pictures of LM colonies and **(D and F)** are graphs that illustrate the mean of number LM colonies formed for all mice  $\pm$  SEM (n=6, Mann-Whitney, TB/STV:  $P > 0.05$ ). **(G)** Graph illustrates the mean  $ERR\alpha$  expression in LM cell colonies after 2 weeks of culture. Semi-quantitative PCR was performed in triplicate on n=3 animals (unpaired t-test:  $P < 0.0001$ ) and normalized against the ribosomal protein gene *L32* (mean  $\pm$ SEM).

**Fig. 3: Overexpression of  $ERR\alpha$  in BCa cells promotes  $CD8^+$  T cytotoxic function.**

Cells suspensions were prepared from metastatic legs (bone) (A, C, D-F) or lungs (B, C) of mice (n=4) inoculated with 4T1-CT or 4T1- $ERR\alpha$  cells. **(A-B)** Flow cytometry contour plots of  $CD45^+$  hematopoietic cells, illustrating the proportion of T cells ( $CD3^+$ ), B cells ( $CD19^+$ ) and  $CD4/CD8$  T cells and graphs representing the percentage of cells in the bone (A) (mean  $\pm$ SD, n = 4, student t-test \*\*  $P < 0.001$ , \*\*\*  $P < 0.0001$ ) and in the lungs (B). **(C)** Flow cytometry contour plots illustrating the production of FasL, LAMP-1, Granzyme A and B and  $IFN\gamma$  in  $CD8^+$  T cells. **(D)** Graphs demonstrate the percentage of cells and **(E)** their absolute numbers. **(F, G)** Fluorescent micrographs of sections of 4T1-CT or 4T1- $ERR\alpha$ -expressing bone after *TUNEL* assay and enlarged views of dashed rectangles. Apoptotic cells are shown in red and the cell nucleus in blue after DAPI staining. (G, H) Scale bar=50 $\mu$ m, T: tumor, GP: growth plate with apoptotic hypertrophic chondrocytes indicated by white arrows.

**Fig. 4:  $CD8^+$  T cell depletion restore 4T1- $ERR\alpha$  BM progression.**

4T1- $ERR\alpha$  cells injected mice were treated with anti- $CD8$  antibodies every two day once osteolytic lesions occur *ie* at day 10 based on radiography **(A)** Flow cytometry analysis confirming the  $CD8^+$  T cell-depletion in the bones. **(B)** Radiography, illustrating representative osteolytic lesions 18 days post- 4T1- $ERR\alpha$  cells inoculation. The osteolytic regions are delimited by dash lines. **(C)** Three-dimensional microCT reconstruction representation of tibiae in sagittal sections

(C) and cross sections (D) following the cutting of the bone along the plane illustrated by the dashed lines in C. (E) Graphs illustrate the mean of the % of Bone Volume/Tissues Volume  $\pm$  SEM (Mann-Whitney, BV/TV:  $P = 0.0037$ ).

**Fig. 5: Ccl17 and Ccl20 up-regulation by ERR $\alpha$  in BCa cells.**

(A) Heat map representative of cytokine, chemokine and growth factor mRNA expression in 4T1-ERR $\alpha$  and 4T1-CT cells, normalized against *Ppia*, *Actb* and *Rplp0* expression. (B-D) Graph illustrates the relative gene expression after RT-PCR performed on triplicate samples and normalized against the ribosomal protein gene *L32* (mean  $\pm$  SEM). (B) 4T1-ERR $\alpha$ , 4T1-CT or 4T1-ERR $\alpha$ AF2, 4T1-CT(af2) cells were analyzed (n=2, ANOVA:  $P < 0.0001$  for *Ccl17* and *Ccl20*, unpaired t-test  $P = 0.0007$  (*Ccl17*),  $P = 0.0005$  (*Ccl20*) (4T1-ERR $\alpha$ ) and  $P = 0.0004$  (*Ccl20*) 4T1-ERR $\alpha$ AF2 versus 4T1-CT). (C-D) 4T1-ERR $\alpha$  and 4T1-ERR $\alpha$ AF2 cells were cultured for 24 hours with the inverse-agonist C29 (5  $\mu$ M) (unpaired t-test,  $P = 0.0005$  and  $P = 0.0034$  for *Ccl17* and *Ccl20*, respectively). (E) Tumor cell colonies obtained after crushing bones extracted from mice (n = 3) bearing either 4T1-ERR $\alpha$  or 4T1-CT lesions and cultured during 4 weeks were analyzed (unpaired t-test  $P = 0.0059$  (*Ccl17*),  $P < 0.0001$  (*Ccl20*) and  $P < 0.0001$  (ERR $\alpha$ )). (F) Immunostaining for Ccl17 and Ccl20 on bone section colonized by either 4T1-ERR $\alpha$  or 4T1-CT cells. Bar = 200  $\mu$ m, T: tumor, GP: growth plate. (G) Representative flow cytometry contour plot illustrating the expression of CCR4 and CCR6 on CD8<sup>+</sup> T cells from bones colonized with either 4T1-ERR $\alpha$  or 4T1-CT cells. All *in vitro* and *ex vivo* analyses were repeated at least twice. Data are plotted as mean  $\pm$  SEM.

**Fig. 6: Over-expression of ERR $\alpha$  in BCa inhibits Tgf- $\beta$  expression and affects TGF- $\beta$  signaling in CD8<sup>+</sup>T cells.** (A) Overlay of the Minimal Network (containing 101 proteins) with extracted information from the Gene-Ontology-consortium of proteins involved in the immune

system process, as well as to create “Minimal Network specific to immune response to tumor” (containing 52 proteins). **(B, C)** Potential new regulators of *ESRRA*, including *VCAM1*, *MACF1*, *HUR* and *TGF- $\beta$ 3*, were identified through systematic shortest path definition of crosstalks. **(D-E)** Graphs illustrating the relative gene expression after RT-PCR performed on triplicate samples and normalized against the ribosomal protein gene *L32* (mean  $\pm$  SEM). **(D)** 4T1-*ERR $\alpha$* , 4T1-*ERR $\alpha$ AF2*, 4T1-CT and 4T1-CT(*af2*) cells were analyzed (ANOVA:  $P < 0.0001$  and unpaired t-test  $P < 0.0001$  4T1-*ERR $\alpha$*  versus 4T1-CT,  $P = 0.0009$  for 4T1-*ERR $\alpha$ AF2* versus 4T1-CT(*af2*)). **(E)** Tumor cell colonies obtained after crushing bones extracted from mice ( $n = 3$ ) bearing either 4T1-*ERR $\alpha$*  or 4T1-CT lesions and cultured during 4 weeks were analyzed (unpaired t-test  $P = 0.0056$ ). **(F)** Immunostaining for *Tgf- $\beta$ 3* on bone section colonized by either 4T1-*ERR $\alpha$* , 4T1-CT cells or 4T1-CT(*af2*) and 4T1-*ERR $\alpha$ AF2* cells. Bar = 200  $\mu$ m, T: tumor, GP: growth plate. **(G)** 4T1-*ERR $\alpha$*  cells were cultured for 24 hours with the inverse-agonist XCT-790 (1  $\mu$ M) (unpaired t-test,  $P = 0.0007$ ). Data are plotted as mean  $\pm$  SEM. **(H)** RT PCR performed on mRNA of MCF7 and B02 clones. Mean of three different cultures for each MCF7 clones are shown for *TGF- $\beta$ 3* (unpaired t-test  $P = 0.0218$  MCF7-*ERR $\alpha$*  versus MCF7-CT; B02 clones: ANOVA:  $P = 0.0027$ , unpaired t-test  $P = 0.007$ : B02-*ERR $\alpha$*  versus B02-CT). **(I)** Representative flow cytometry histogram plot illustrating the phosphorylation of SMAD2/3 in CD8<sup>+</sup> T cells from bones colonized with either 4T1-*ERR $\alpha$*  cells or 4T1-CT. The percentage of positive cells is illustrated. These *ex vivo* data are representative of 2 experiments with 3-4 mice per group. All *in vitro* analyses were repeated at least twice.

**Table 1: Correlation in clinics in BCa patients.** **(A, B)** Meta-analysis of public datasets (GSE12276-GSE2034-GSE2603) ( $n=248$ ) revealed a positive correlation between the expression of *ESRRA* and *CCL17* and *CCL20* and a negative correlation with *TGF- $\beta$ 3* expression levels in luminal **(A)** and triple-negative **(B)** breast tumors. Correlation scores were

calculated using the Pearson correlation coefficient. P-values less than 0.05 were considered statistically significant.

**Abbreviations used in this paper:** ANOVA: analysis of variance; BM: Bone Metastases; B BV/TV: Bone Volume/Tissues Volume; CCL17-CCL20: Chemokine (C-C motif) ligand 17, 20; CCR4 and CCR6: C-C chemokine receptor type 4 and 6; ERR: estrogen receptor-related receptor; LAMP-1: Lysosome-associated membrane glycoprotein-1; LM: Lung Metastases; OCs: osteoclasts; RANKL: receptor activator of nuclear factor kB ligand; RT: reverse transcription; PCR: polymerase chain reaction; PMN-MDSC: Poly-MorphoNuclear Myeloid Derived Suppressor cells; TNBC: Triple-negative breast cancer; TGF- $\beta$ : Transforming Growth Factor Beta; TB/STV: Burden /Soft Tissues Volume.
