## Introduction

- In nature, kleptoparasitism, the stealing of resources, occurs across species including insects, birds, fish, and mammals.
- We consider kleptoparasitic interactions between two individuals - Owner and Intruder. The Owner is in a possession of a resource when it spots Intruder. The Owner has to decide whether to defend the resource. If the Owner defends, the Intruder has to decide whether to fight with the Owner.
- We determine under what conditions should they fight over a resource.
- The conditions also depend on three distinct information cases:
  - Full information: the Owner and Intruder know the resource values for themselves and each other.
  - Partial information: the Owner and Intruder only know the resource value for themselves.
  - No Information: the Owner and Intruder do not know the resource values for themselves and each other.

## Mathematical model

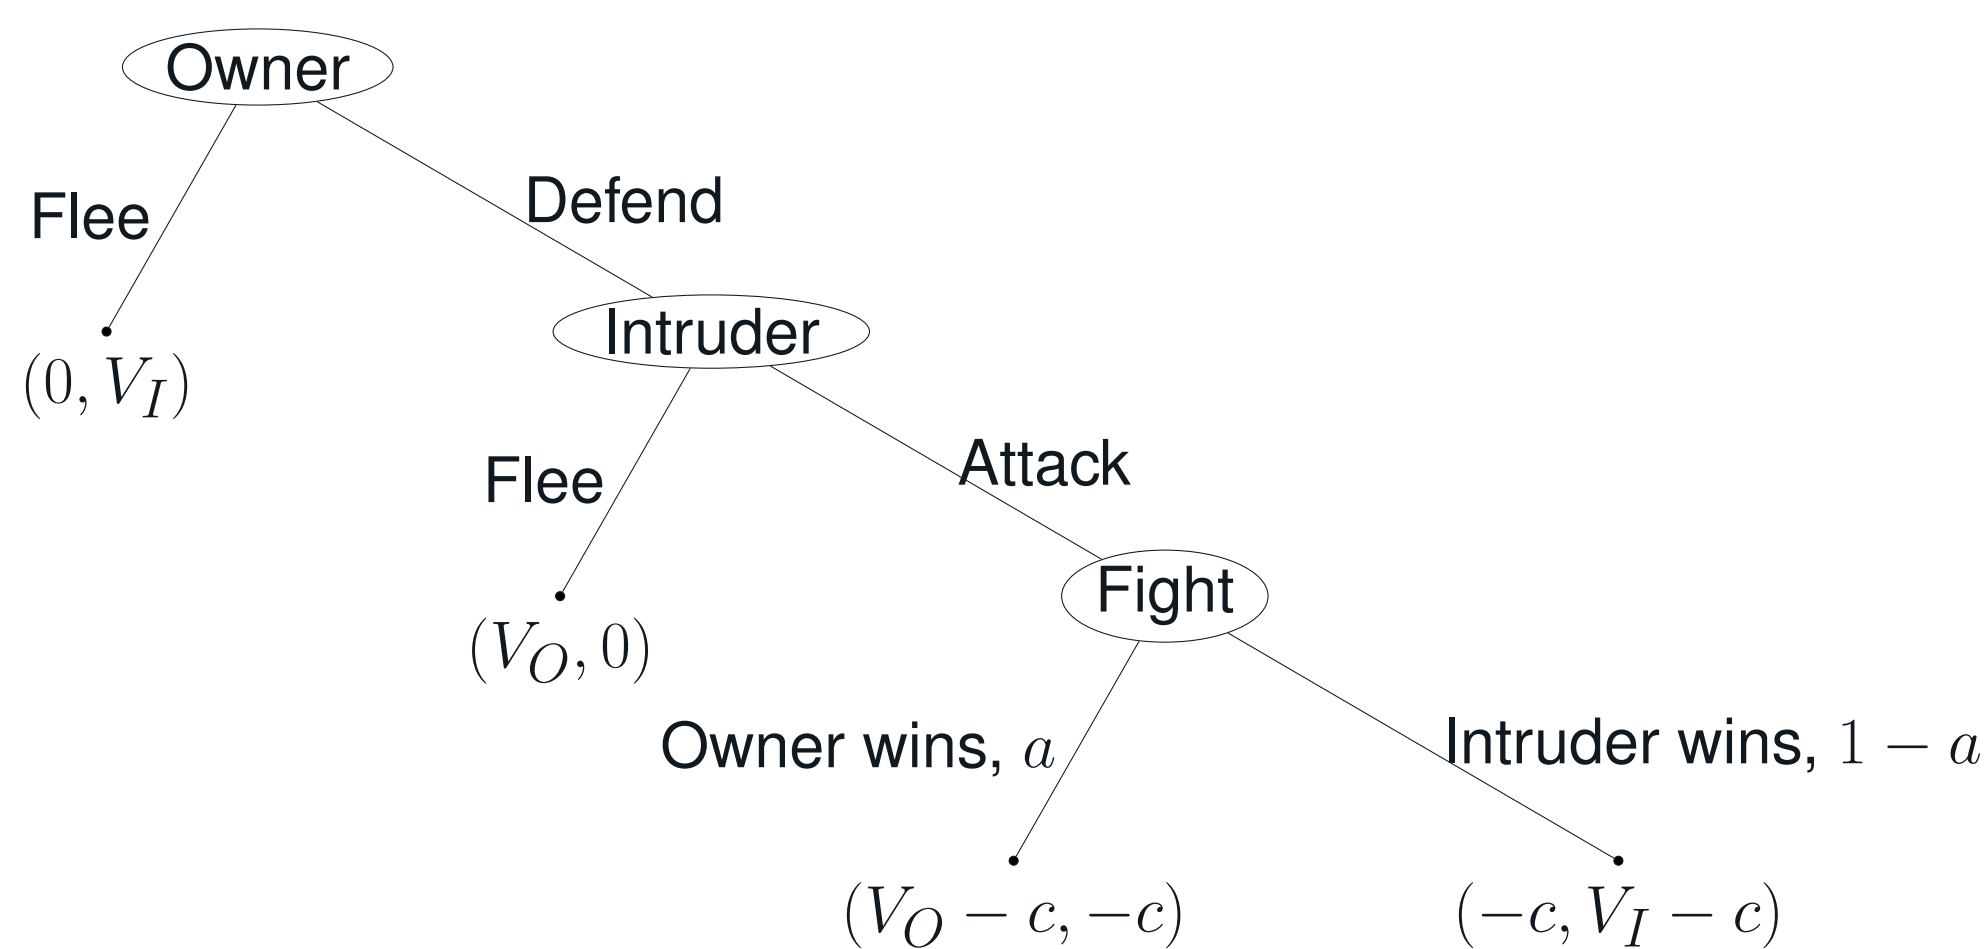

Fig. 1: Scheme and payoffs of the Owner-Intruder game. In the terminal nodes,  $(P_O, P_I)$  means payoffs to the Owner and Intruder. The game is solved by backward induction.

Notation	Meaning
$V_I$	Value of the resource for the Intruder
$V_O$	Value of the resource for the Owner
$c$	Cost of the fight
$a$	Probability of the Owner winning the fight
$\pi_I$	Probability that the Intruder will attack; $\pi_I = \text{Prob}\left(\frac{c}{1-a} < V_I\right)$
$\pi_O$	Probability that the Owner will defend; $\pi_O = \text{Prob}\left(\frac{c}{a} < V_O\right)$
$P_O^{\text{Info case}}$	Payoff to the Owner in the given information case
$P_I^{\text{Info case}}$	Payoff to the Intruder in the given information case
$E[V]$	Expected value of the resource for the Owner or Intruder

Table 1: Summary of the notation.

## Results

Behavior and Payoffs		Full information	Partial information	No information
Owner	Intruder			
Defends	Flees	$\frac{c}{1-a} > V_I$	any $V_O$	$\frac{c}{1-a} > V_I$
		$\frac{c}{1-a} > V_I$	$\frac{c}{1-a} > V_I$	$\frac{\pi_I c}{1-(1-a)\pi_I} < V_O$
		$\frac{c}{1-a} > E[V_I]$		
Defends	Attacks	$\frac{c}{1-a} < V_I$	$\frac{c}{a} < V_O$	$\frac{c}{1-a} < V_I$
		$aV_O - c$	$(1-a)V_I - c$	$\frac{\pi_I c}{1-(1-a)\pi_I} < V_O$
		$\frac{c}{1-a} < E[V_I]$	$\frac{c}{a} < E[V_O]$	$\frac{c}{a} < E[V_O]$
Flees	Takes over	$\frac{c}{1-a} < V_I$	any $V_I$	$\frac{c}{1-a} < V_I$
		$\frac{c}{a} > V_O$	$\frac{\pi_I c}{1-(1-a)\pi_I} > V_O$	$\frac{c}{1-a} < E[V_I]$
		$\frac{c}{a} > E[V_O]$		$\frac{c}{a} > E[V_O]$

Table 2: Summary of behavioral outcomes and payoffs.

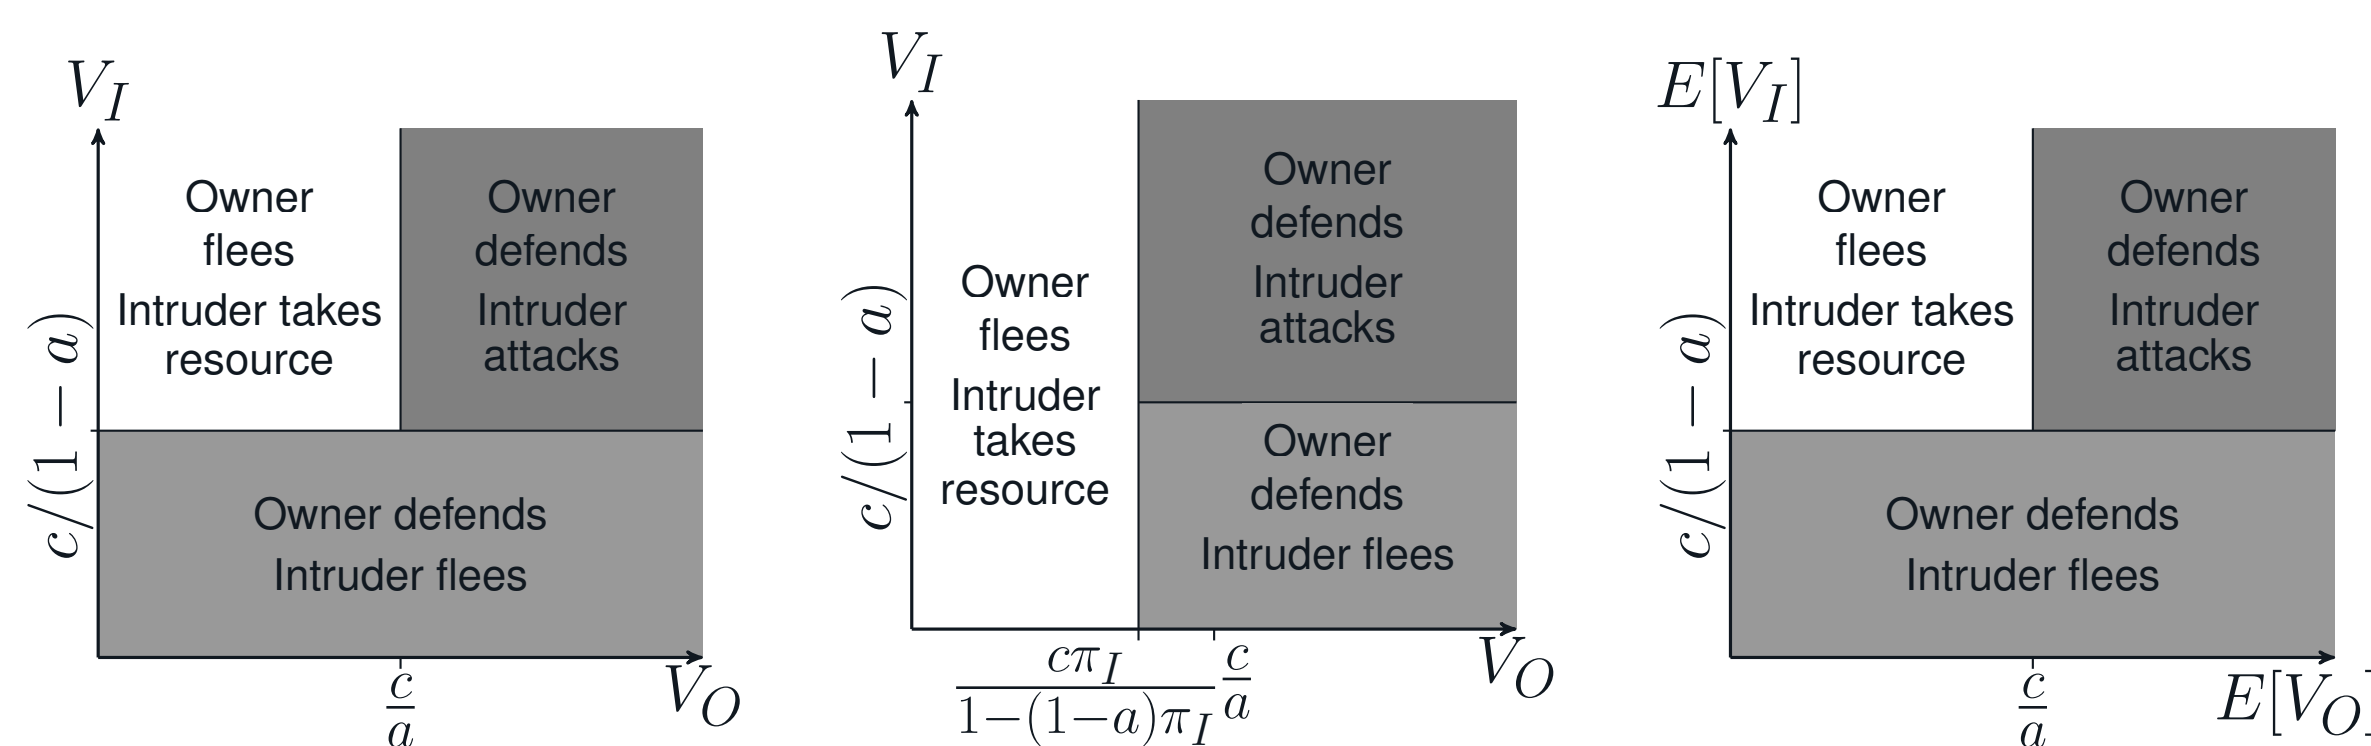

Fig. 2: Behavioral outcomes of the game for the different information cases. The payoffs depend on the behavior of the Owner and Intruder and are as follows: 1) when Owner defends and Intruder flees:  $P_O = V_O, P_I = 0$ , 2) when Owner defends and Intruder attacks:  $P_O = aV_O - c, P_I = (1-a)V_I - c$ , 3) when Owner flees and Intruder takes the resource:  $P_O = 0, P_I = V_I$ .

Left: Full information case. Center: Partial information case. Right: No information case

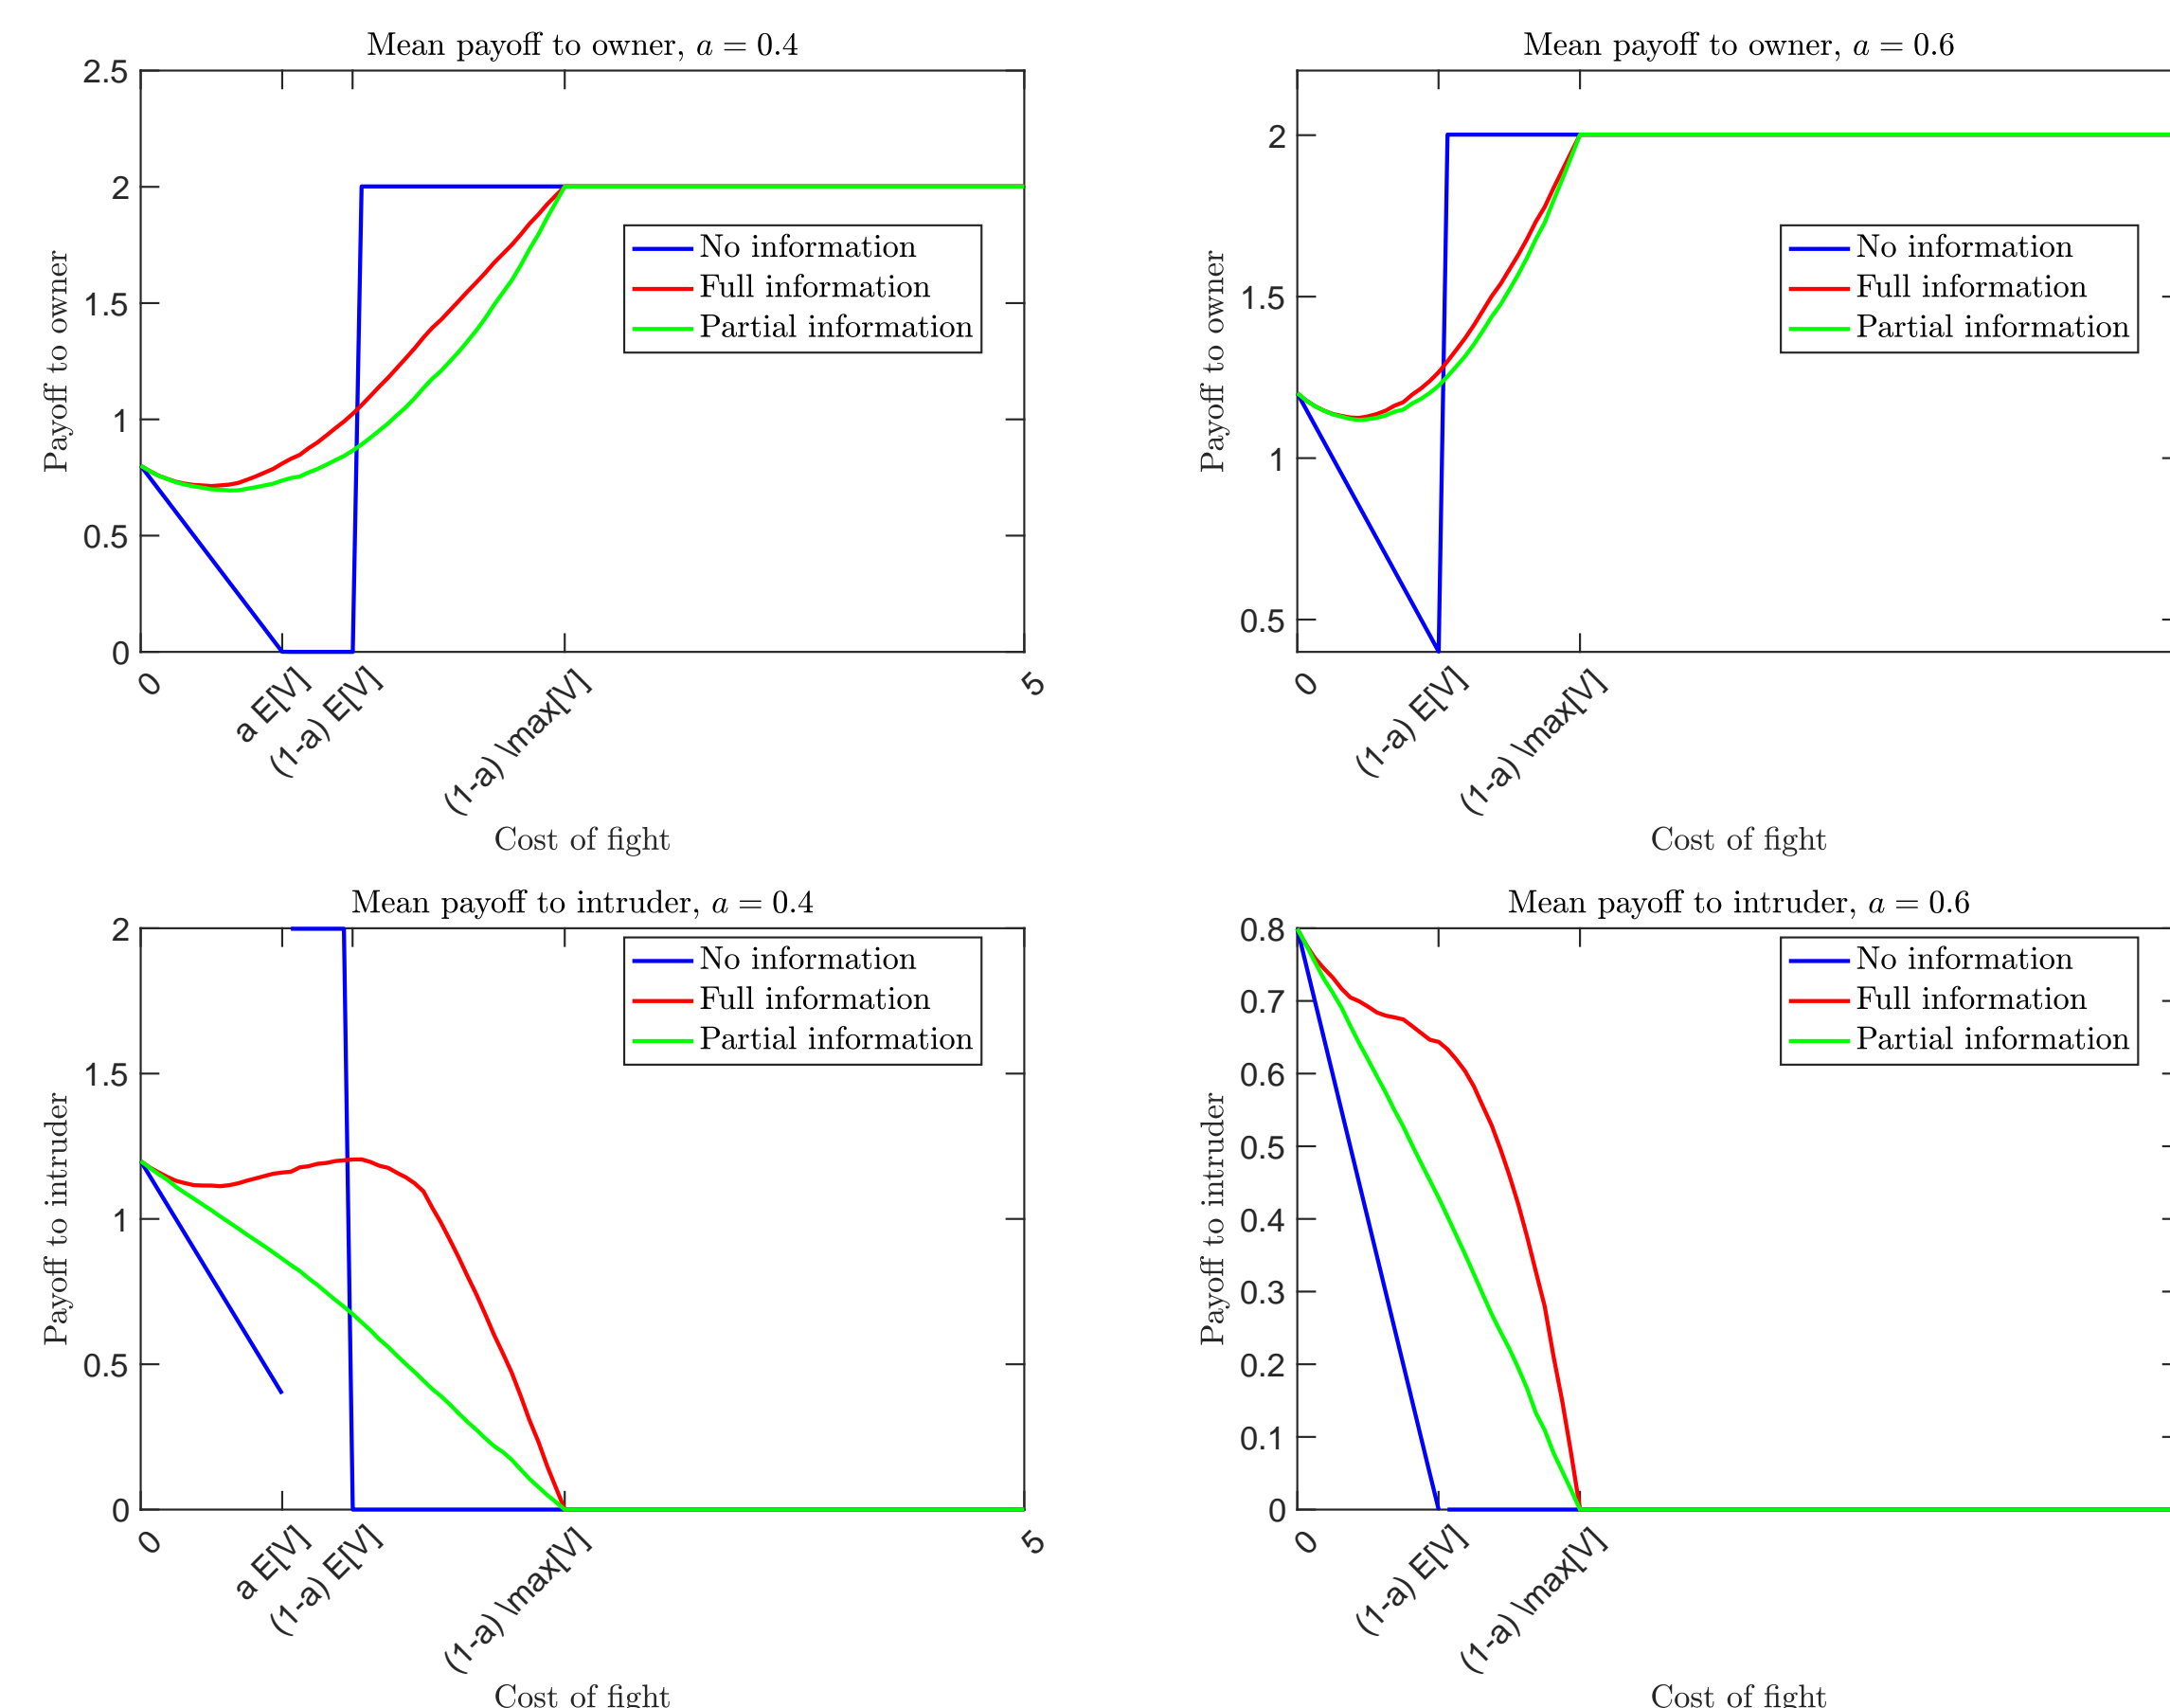

Fig. 3: Mean payoffs to the Owner (top) and Intruders (bottom) under different information cases. Here  $c$  varies,  $V_O$  and  $V_I$  are drawn from the uniform distribution on  $(0, 4)$  and  $a = 0.4$  (left) or  $a = 0.6$  (right).

## Changing the order of players

- In the full information and the no information case, the order of players matters only for small values of  $V_O$  and  $V_I$ .
- The individual deciding first has an advantage - it bluffs by pretending to be ready to fight; the fight is too costly for the other individual to call the bluff.
- In the partial information case, there are four regions where the order matters.

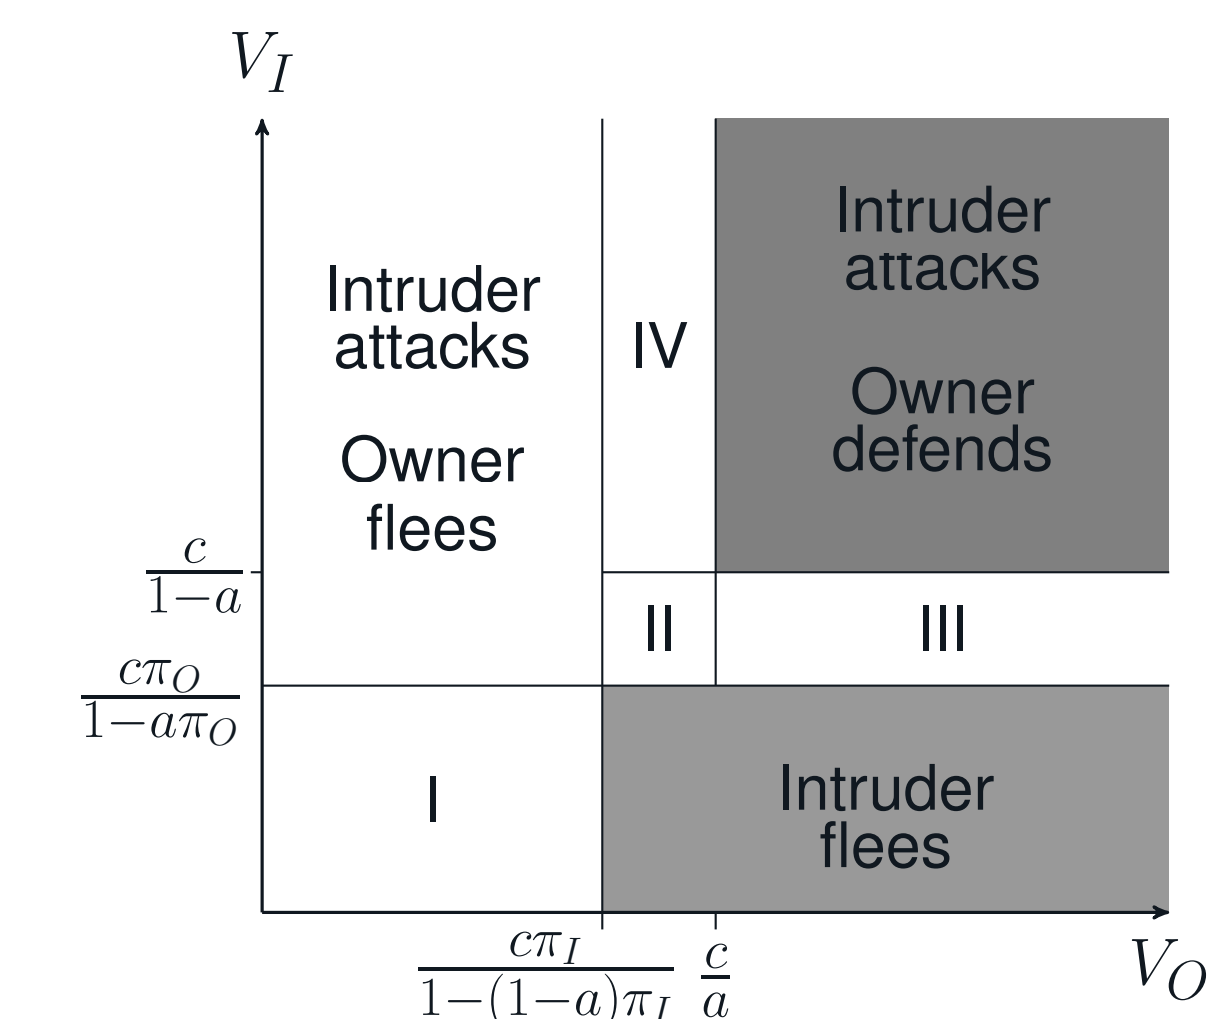

Fig. 4: Partial information case - the effect of the order of the decisions. Region I: The second individual has an advantage. Region II: The first individual has the advantage. Region III: It is better for the Owner to go first and for the Intruder to go second. Region IV: It is better for the Intruder to go first and for the Owner to go second.

## Conclusions

- The actual fights occur only when the cost of the fight is relatively low compared to the resource value. This is in an agreement with previous experiments.
- Under most circumstances, it is beneficial for the individual to know more rather than to know less.
- However, the no information case is sometimes best for the Owner (because the Intruder will flee and not fight).
- Increasing the opponent's knowledge may be helpful in some instances and detrimental in others.
- The order of players matters - going first is better in most circumstances, but going second is sometimes best in the partial information case.

## Acknowledgements

The work on this project was done as part of the course MATH/BIOL 380 - Introduction to mathematical biology. We acknowledge the help and support of our classmates, the instructor Dr. Rychtar, and Dr. Taylor.
