15 **Abstract**

16 *Lactobacillus brevis* beer-spoiling strains harbor plasmids that contain genes such as *horA*,
17 *horC* and *hitA*, which are known to confer hop tolerance. The *Lb. brevis* beer-spoiling strain
18 UCCLBBS124, which possesses four plasmids, was treated with novobiocin resulting in the
19 isolation of UCCLBBS124 derivatives exhibiting hop-sensitivity and an inability to grow in
20 beer. One selected derivative was shown to have lost a single plasmid, designated here as
21 UCCLLBS124_D, which harbors the *UCCLBBS124_pD0015* gene, predicted to encode a
22 glycosyltransferase. Hop tolerance and growth in beer was restored when
23 *UCCLBBS124_pD0015* was introduced in one of these hop-sensitive derivatives on a
24 plasmid. We hypothesize that this gene modifies the surface composition of the
25 polysaccharide cell wall conferring protection against hop compounds. Furthermore,
26 introduction of this gene *in trans* in *Lb. brevis* UCCLB521, a strain that cannot grow in and
27 spoil beer, was shown to furnish the resulting strain with the ability to grow in beer while its
28 expression also conferred phage-resistance. This study underscores how the acquisition of
29 certain mobile genetic elements plays a role in hop tolerance and beer spoilage for strains of
30 this bacterial species.

31 **Importance**

32 *Lactobacillus brevis* is a member of the lactic acid bacteria and is often reported as the
33 causative agent of food or beverage spoilage, in particular that of beer. Bacterial spoilage of
34 beer may result in product withdrawal or recall with concomitant economic losses for the
35 brewing industry. A very limited number of genes involved in beer spoilage have been
36 identified and primarily include those involved in hop resistance such as *horA*, *hitA*, and
37 *horC*. However, since none of these genes are universal, it is clear that there are likely (many)
38 other molecular players involved in beer spoilage. Here, we report on the importance of a
39 plasmid-encoded glycosyltransferase associated with beer spoilage by *Lb. brevis* that is

40 involved in hop tolerance. The study highlights the complexity of the genetic requirements to

41 facilitate beer spoilage and the role of multiple key players in this process.

42 **Introduction**

43 *Lactobacillus brevis* is a major threat for commercial and amateur brewers as strains
44 of this species are the predominant bacterial contaminants associated with beer spoilage (1).
45 Such *Lb. brevis* strains can grow in beer despite the presence of ethanol, low pH and the
46 depletion of oxygen and nutrients (2). Moreover, hop compounds added to beer for bitter
47 flavor development during the fermentation process also exert antibacterial activity through
48 the presence of *iso*-α-acids (1, 2). *Lb. brevis* beer-spoiling (BS) strains appear to have
49 acquired chromosomally- or plasmid-derived genetic content to survive and grow in beer (2).
50 *Lb. brevis* resistance to ethanol (up to 10 %) and pH lower than the optimal growth
51 conditions (pH 4-6) seems to be associated with chromosomal genes, possibly due to the
52 general stressors they represent (3, 4). However, *Lb. brevis* BS strains are also known to
53 harbor plasmids that are associated with their beer-spoilage phenotype and more specifically
54 with hop tolerance (5-8). Plasmid-derived genes that underpin hop-resistance in *Lb. brevis*
55 include *horA, horC, hitA* and *orf5*$_{ABBC45}$ (1, 2). The genes *horA* and *horC* encode multidrug
56 transporter proteins driven by ATP and proton motive force (PMF), respectively, and were
57 identified as being involved in *iso*-α-acid extrusion from the bacterial cell (5, 7). The gene
58 *hitA* encodes a transmembrane protein involved in the transport of divalent cations such as
59 Mn^{2+} in exchange of protons released from hop bitter acids (8). The *orf5*$_{ABBC45}$ gene was
60 identified in *Lb. brevis* BS strain ABBC45 which was unable to grow in beer after it had lost
61 a plasmid carrying this gene. The *orf5*$_{ABBC45}$ gene encodes a predicted transmembrane protein
62 resembling a PMF-dependent multidrug transporter, which is presumed to be responsible for
63 *iso*-α-acid export (9).

64 However, these genes are not always indicative of BS ability as the presence of such
65 genes can be found among *Lb. brevis* strains that are unable to grow and consequently spoil
66 beer (designated here as NBS strains) (10). Indeed, *horA* is present in the *Lb. brevis* NBS

Accepted Manuscript Posted Online

Downloaded from http://aem.asm.org/ on February 7, 2020 at IRIS

67 strain UCCLB556 (10). Moreover, genes identified as conferring hop-resistance are not
68 always simultaneously present in BS strains, e.g. the BS strain UCCLBBS124 carries
69 plasmids harboring *horA* and *horC*, however it does not possess *hitA* (10). Analysis of BS
70 strain *Lb. brevis* BSO 464 has highlighted the importance of plasmids and genes on mobile
71 genetic elements for bacterial growth in beer and beer spoilage ability (6). Recently, a gene
72 predicted to encode a glycosyltransferase was identified among BS strains responsible for
73 excess β-glucan formation (11). This gene is also present on the genome of *Lb. brevis* BS
74 strain UCCLBBS124, while it is absent in that of BS strain UCCLBBS449 (10). This
75 indicates that beer spoilage is not uniquely governed by the presence of a few genes, but
76 rather a combination of genes acting in concert to confer beer resistance to the strain. It also
77 suggests that other plasmid-encoded genes involved in beer spoilage are yet to be discovered.

78 In the present study we generated plasmid-cured derivatives of *Lb. brevis* BS strain
79 UCCLBBS124 using novobiocin. This approach has been successfully employed previously
80 to cure plasmids from lactic acid bacteria (LAB) isolates (6, 12). Plasmid-cured derivatives
81 were assessed for their ability to grow in the presence of hop and in beer. A derivative that
82 showed inability to grow in beer was selected and analyzed to ascertain which plasmids were
83 responsible for this phenotype. Bioinformatic analysis of the genetic content of such plasmids
84 revealed candidate genes required for growth in beer. These genes were used in
85 transformation experiments to revert the NBS phenotype.

88 **Results and Discussion**

89 *Derivatives with impaired growth in beer reveal loss of plasmid UCCLBBS124_D*

90 The beer-spoiling *Lb. brevis* strain UCCLBBS124 (abbreviated here as UCC124) possesses
91 four plasmids carrying genes of interest for bacterial beer spoilage (Table 3). Following
92 exposure to novobiocin, surviving *Lb. brevis* UCC124 cells were plated and fifty isolated
93 colonies (10) were randomly selected for further analysis. Thirty four of these fifty colonies
94 displayed impaired growth in beer. PCR-based identification of the hop-resistance gene *horA*
95 revealed the loss of this gene, located on plasmid UCCLBBS124_D (abbreviated here as
96 UCC124_D) in 33 out of the 34 isolates. One derivative, designated here as MB569, was
97 selected for genome sequencing, after which its sequence was compared to that of the WT,
98 confirming that plasmid UCC124_D had been lost from strain MB569.

99 *Tolerance of MB569 to iso-α-acids, ethanol and low pH*

100 The inability of strain MB569 to grow in beer highlights the apparent importance of plasmid
101 UCC124_D in conferring a beer spoilage phenotype on strain UCC124 (Figure 1). Beer is a
102 harsh environment incorporating a number of stresses such as low pH, lack of nutrients, and
103 the presence of ethanol and hop compounds. In order to understand which of these stresses
104 imposed a negative impact on growth of MB569, the WT strain and MB569 were grown in
105 MRS broth and mimicking conditions encountered in beer, e.g. pH4, 5.4 % ethanol, and 30
106 ppm *iso*-α-acids. Strain MB569 was shown to be capable of growth in MRS broth at neutral
107 pH and at pH 4, while it can also grow in the presence of ethanol comparable to the WT
108 strain (Figure 1). However, MB569 is incapable of growth in the presence of *iso*-α-acids
109 unlike the WT strain UCC124 (Figure 1). This indicates that plasmid-cured derivative
110 MB569 has lost the ability to spoil beer due to its sensitivity to the antimicrobial compounds
111 present in hops. Therefore, based on this phenotype and the finding that MB569 lacks

112 plasmid UCC124_D (when compared to its parental strain), it indicates that this plasmid is
113 linked to hop tolerance and thus contributing to the ability of strain UCC124 to cause beer
114 spoilage.

115 *Identification and functional annotation of genes present on plasmid UCC124_D*

116 Plasmid UCC124_D is 21 kb in size and is predicted to encompass 16 genes. Interestingly, a
117 7 kb region of this plasmid, contains six genes that are uniquely present among the plasmids
118 of *Lb. brevis* BS strains (Table 4) (10). In order to assess the possible role of these genes in
119 beer spoilage, the BS plasmid-specific genes *UCCLBBS124_pD0014* (abbreviated here as
120 *UCC124_D14)*, encoding a predicted cytosine deaminase*, UCCLBBS124_pD0015* (renamed
121 gtf_{D15}), encoding a predicted glycosyltransferase*, UCCLBBS124_pD0016* (designated here as
122 *UCC124_horA*), which encodes HorA (Table 4), were individually cloned into plasmid
123 pNZ44 prior their transformation into NZ9000. The resulting plasmids were then introduced
124 into strain MB569 to determine the ability of the obtained recombinant strains to grow in beer
125 (where MB569 itself is unable to do so). Genes with locus tags *UCCLBBS124_pD0017*
126 (abbreviated as UCC124_D17)*, UCCLBBS124_pD0018* (abbreviated as UCC124_D18) and
127 *UCCLBBS124_pD0019* (abbreviated as UCC124_D19) and encoding acyl-sn-glycerol-3-
128 phosphate acyltransferases and a glycosyltransferase (Table 4) were cloned together as a
129 cluster (as present in plasmid UCC124_D) in pNZ44 prior their introduction into NZ9000
130 and, subsequently, MB569.

131 Introduction of the genes *UCC124_D14*, *UCC124_horA*, *UCC124_D17, UCC124_D18* and
132 *UCC124_D19* in MB569 did not enable any obvious improvement of growth in the presence
133 of *iso*-α-acid (30 ppm) or beer (when compared to strain MB569) (data not shown).

134 Interestingly, expression of gtf_{D15} in MB569 was shown to confer a positive effect on its
135 ability to grow in MRS broth containing 30 ppm *iso*-α-acids, with a significant (P value <

Applied and Environmental Microbiology

Downloaded from http://aem.asm.org/ on February 7, 2020 at IRIS

136 0.05) growth increase after 72 h compared to the non-complemented strain or MB569
137 carrying the control plasmid pNZ44 (Figure 2A). When *Lb. brevis* MB569 pNZ44:gtf_{D15} was
138 cultivated in beer, it also exhibited an ability to grow in beer that was significantly better than
139 that of MB569 itself (P value < 0.05) (Figure 2B). Provision of gtf_{D15} *in trans* in MB569 did
140 not restore its growth in beer to the same level as the WT strain (i.e. the strain from which
141 MB569 was derived), but nonetheless allowed survival and growth in beer for this
142 recombinant strain across 96 h. MB569 and MB569 pNZ44 are still able to survive in the
143 presence of *iso*-α-acids or beer after culture for 72 h (Figure 2A and 2B) which might be due
144 to the presence of plasmid UCCLBBS124_C carrying the gene *horC* (Table 3). The gtf_{D15}
145 gene is predicted to encode a glycosyltransferase based on BLAST analysis and a HHPred
146 analysis (13) predicted the protein to belong to the glycosyl transferase family 8 associated
147 with cell wall glycosylation (99.9 % probability and E-value < 10^{-28}). Further sequence
148 scrutiny suggests that the Gtf_{D15} protein is a membrane-associated protein (TMHMM Server
149 2.0 (14)) with a predicted signal peptide in its N-terminus that may act as a membrane anchor
150 for the protein (http://phobius.sbc.su.se/ (15)). These predictions suggest that GtfD15 is a cell
151 envelope-associated protein that confers protection against certain environmental stressors
152 such as hop compounds.

153 *Introduction of* gtf_{D15} *in NBS Lb. brevis strains allows growth in beer*

154 The introduction of gtf_{D15} in MB569 was shown to significantly improve growth of the strain
155 in MRS broth containing hop compounds (30 ppm *iso*-α-acids) and in beer indicating the
156 importance of this gene for beer spoilage by *Lb. brevis* strain UCC124. In order to assess the
157 potential growth-promoting effect of this gene for an NBS strain when inoculated in beer,
158 gtf_{D15} when cloned into pNZ44 (pNZ44:gtf_{D15}) was introduced into the NBS *Lb. brevis* strain
159 UCCLB521 (renamed here as UCC521) (Table 1). Remarkably, the presence of pNZ44:gtf_{D15}
160 in the NBS strain *Lb. brevis* UCC521 permitted the strain to grow significantly better (P

Accepted Manuscript Posted Online

161 value < 0.05) in MRS broth containing 30 ppm *iso*-α-acids and in beer compared to the strain
162 carrying an empty plasmid which is incapable of survival or growth in these environments
163 (Figure 2C and D). These observations reinforce our results above and highlight the
164 significance of the gtf_{D15} gene in hop tolerance and beer spoilage. An alternative, though in
165 our opinion less likely explanation is that strains for which we obtained no or reduced CFUs
166 had entered a viable, but non-culturable (so-called VBNC) state as has been previously
167 observed for beer-passaged *Lb. brevis* strains (16).

168 Introduction of pNZ44:gtf_{D15} into ATCC 367, another NBS strain, did not allow improved
169 survival or growth in the presence of hop compounds or in beer (data not shown). This
170 suggests that a strain-specific mechanism and involvement of other genes that are absent in
171 ATCC 367 are responsible for increased hop tolerance. Among beer spoilage-related genes,
172 UCC521 possesses the $orf5_{ABBC45}$ gene previously identified as involved in hop tolerance (9),
173 unlike ATCC 367 which does not harbor known genes involved in beer spoilage. Moreover,
174 UCC521, although a non-beer spoiler strain, was isolated from the brewery environment,
175 unlike ATCC 367 which was isolated from silage (10). UCC521 may have acquired genes
176 (such as $orf5_{ABBC45}$) or plasmids (UCC521 harbors five plasmids) throughout its presence in
177 the brewery environment, which confer hop tolerance when combined with gtf_{D15}. This
178 scenario has previously been observed, indicating that *Lb. brevis* strains can only survive and
179 grow in beer when multiple beer spoilage-related genes are present in a particular
180 combination (17). Selection pressures of the beer environment determine the genetic content
181 of beer-spoiling strains. The identification of diagnostic marker genes (DMGs) are important
182 in distinguishing BS from NBS strains, as well as predicting the ability of a given strain to
183 grow in beer (17, 18). In the study from Bergsveinson and Ziola, proposed DMGs were not
184 related to hop tolerance and no genes encoding glycosyltransferases were identified as
185 DMGs. However, a glycosyltransferase-encoding gene located on the plasmid of the BS *Lb.*

186 *brevis* strain BSO 464 which showed more than 99 % nt similarity to gtf_{D15} was described as
187 unique when compared to a NBS *Lb. brevis* strain KB290 and a BS *Pediococcus damnosus*
188 strain Pc344^{T} (17). From these observations and knowing that gtf_{D15} is highly prevalent in BS
189 *Lb. brevis* strains (Table 4), we propose to include this gene as a DMG to assess the beer
190 spoiling potential of *Lb. brevis* strains.

191 *Effect on phage sensitivity*

192 As demonstrated above gtf_{D15} was observed to play a role in hop and beer tolerance and is
193 predicted to encode a glycosyltransferase. Since the protein is predicted to be involved in
194 biosynthesis or modification of a cell surface-associated saccharidic polymer, the possible
195 role of this protein in bacteriophage infection was investigated. *Lb. brevis* strain UCC521 is
196 sensitive to *Lb. brevis* phages 3-521 and 521B (19). Plaque assays employing these phages
197 and *Lb. brevis* UCC521 harboring the empty vector pNZ44, or strain UCC521 containing
198 pNZ44:gtf_{D15} displayed similar EOP (Efficiency Of Plaquing) values with no significant
199 difference to the WT (Table 5). However, notable differences in plaque morphology were
200 observed, where plaques were faint and hard to distinguish on the bacterial lawn of UCC521
201 pNZ44:gtf_{D15}. Moreover, overnight incubation of the different strains with the two phages led
202 to complete lysis-in-broth of UCC521 and UCC521 containing pNZ44 with an approximately
203 1000-fold increase of phage titre after overnight propagation (Table 5). In contrast, UCC521
204 pNZ44:gtf_{D15} did not show visible lysis and was able to grow after overnight incubation with
205 just a ten-fold increase in phage numbers after overnight propagation (Table 5). These results
206 reinforce the role of the protein Gtf_{D15} in bacterial protection against diverse environmental
207 hazards such as hop compounds or bacteriophages.

210 **Conclusions**

211 In this study, we identified a novel genetic component required for beer spoilage and more
212 specifically for hop tolerance. This gene is located on plasmid UCC124_D of *Lb. brevis* BS
213 strain UCC124, validating the importance of plasmids to confer a beer spoilage phenotype.
214 Moreover, this gene had been highlighted previously as common among BS strains (10).
215 Genes required for hop tolerance have all been identified on plasmids (5, 7, 8), reinforcing
216 the importance of such mobile genetic elements in adaptation to the specific hurdles imposed
217 by the beer environment. A derivative of UCC124, MB569 showed impaired growth in beer
218 after the loss of plasmid UCC124_D and despite the presence of plasmids UCC124_B and
219 UCC124_C which carry several genes of interest in beer spoilage. Introduction of gtf_{D15} in
220 strain MB569 restored the hop tolerance phenotype of the strain which ultimately allowed it
221 to grow in beer. Similar results were observed when the gene was introduced into a NBS
222 strain confirming the notion that gtf_{D15} is required for the development of hop tolerance and
223 beer spoilage. Furthermore, this gene impacts on phage sensitivity of its host. This gene
224 seems a unique trait shared among BS strains of *Lb. brevis* and we propose gtf_{D15} as a DMG
225 for the detection of potential bacterial contamination of beer. The gene is predicted to encode
226 a glycosyltransferase and analysis of its topology suggests that it is a membrane-anchored
227 protein involved in the biosynthesis or modification of a cell surface-associated saccharidic
228 polymer. BS strains of *Lb. brevis* have been shown to increase higher molecular weight
229 lipoteichoic acids (LTA) in their cell wall, in the presence of hop bitter acids, thus believed to
230 confer resistance to the bacteria by enhancing the barrier functions of the cell wall and
231 preventing intrusion of hop compounds (20, 21). Moreover, lipoteichoic acids have been
232 described as phage receptors among lactobacilli phages as seen for *Lactobacillus delbrueckii*
233 phages LL-H and JCL1032 (22) but also for *Lactobacillus plantarum* ATCC8014-B2 (23).
234 Therefore, we speculate that this glycosyltransferase is involved in replacing alanine residues

Accepted Manuscript Posted Online

235 with sugar residues on teichoic acids thereby changing their charge and preventing *iso*-α-
236 acids to penetrate the membrane as well as affecting phage adsorption and/or DNA injection.
237 This predicted glycosyltransferase shows only limited similarity (36 % amino acid similarity
238 in 20 % query cover) with the glycosyltransferase identified in a previous study as
239 responsible for β-glucan formation (11), and is thus believed to play a different role in beer
240 spoilage. Future studies will focus on defining the mechanism that underpins hop tolerance
241 and on determining how the genes identified to date (5, 7, 8) are linked to each other.
242 Moreover, located on the same plasmid as gtf_{D15} are genes predicted to encode a
243 glycosyltransferase and acyltransferases (Table 2) suggesting a common action on teichoic
244 acids with the acyltransferases involved in the acylation of alanine residues or the lipid
245 moiety of the lipoteichoic acids (24). Follow-up work may therefore focus on determining the
246 precise function of the glycosyltransferase (and other associated genes) in the modification of
247 the cell wall and/or cell surface. Another question to be addressed is if and how hop tolerance
248 is enhanced when these genes are present in a certain combination, and how such tolerance is
249 influenced by their expression level.

252 **Materials and Methods**

253 *Bacterial strains and cultivation media*

254 Bacterial strains used in this study are listed in Table 1. *Lb. brevis* strains were grown in
255 MRS broth (Oxoid Ltd., UK) at 30 ˚C while *Lactococcus lactis* NZ9000 was grown in M17
256 broth (Oxoid Ltd., UK) supplemented with 0.5 % glucose. 5 µg/mL chloramphenicol (Cm5)
257 was added to the medium when indicated.

258 *Plasmid curing and plasmid content analysis*

259 The overall experimental approach is presented in Figure S1. Plasmid curing of the BS strain
260 UCC124 was achieved using novobiocin treatment (25). A 1 % inoculum of a WT strain
261 overnight culture was used to inoculate 10 mL MRS broth containing 0.25 µg/mL
262 novobiocin. Cultures were incubated at 26 °C for 72 h. After incubation, cells were diluted
263 and plated on MRS agar. After 3 days of incubation at 26 °C, isolated colonies were
264 randomly selected and derivatives with impaired growth in beer (no growth observed after 72
265 h) were checked for the presence or loss of hop-resistance genes *horA*, *horC* and $orf5_{ABBC45}$
266 (Table 2). A derivative showing loss of hop-resistance gene was selected and sequenced
267 using Illumina sequencing technology. Paired-end sequence reads were generated using an
268 Illumina HiSeq2500 system (read length 2 x 250 bp). FASTQ sequence files were generated
269 using the Illumina Casava pipeline version 1.8.3. After Illumina sequencing the obtained
270 sequences were mapped back against the WT reference sequence to detect mutations by
271 single nucleotide polymorphism (SNP) or plasmid content loss. SNP analysis was performed
272 by aligning Illumina raw reads against a reference sequence using Bowtie2 V 2.3.5 (26). The
273 reads were then sorted using Samtools (27) and VarScan v2.3.9 was applied for the detection
274 of variants (28). A minimum allelic variation frequency cut-off of 0.25 was applied.

275 *Construction of plasmid vectors*

Accepted Manuscript Posted Online

276 Genes of interest were amplified by PCR (Table 2) and cloned into the expression vector
277 pNZ44 (29). PCR products and pNZ44 plasmid DNA were digested with the appropriate
278 enzymes (Roche, USA) at 37 ˚C for at least 4 h, following the manufacturer's instructions
279 (Table 2). A ratio of (3:1) was applied for the ligation of the PCR product with pNZ44 using
280 T4 DNA ligase (Promega, USA). The mixture was incubated at room temperature for at least
281 4 hours prior to electrotransformation into *L. lactis* NZ9000 competent cells.

282 *Preparation of competent cells and electrotransformation*

283 Competent cells of *L. lactis* NZ9000 were prepared as previously described (30). Competent
284 cells of *Lb. brevis* UCC124 were prepared using an adapted version of a previously described
285 protocol (31): An overnight culture was transferred (1 % inoculum) to 10 mL MRS broth
286 containing 1 % glycine and incubated overnight at 30 ˚C. 5 mL of the overnight culture was
287 transferred to fresh MRS broth containing 1 % glycine (50 mL final volume) and cells were
288 grown to an OD_{600nm} of 0.6. Cells were harvested by centrifugation at 4,000 × *g* for 15 min at
289 4 ˚C and washed in ice-cold wash buffer (0.5 M sucrose, 10 % glycerol). The wash step was
290 repeated twice and the cells were finally resuspended in 200 µL wash buffer prior to storage
291 at -80 ˚C and/or electroporation (see below). All constructs were generated using *L. lactis*
292 NZ9000 as the cloning host, verified by sequencing after PCR amplification using the
293 primers pnz44F and pnz44R (Table 2) prior to their transfer into *Lb. brevis* strains.
294 Electrotransformation was performed using freshly prepared competent cells as described
295 above, where 45 µL of cells and 5 µL of plasmid construct were mixed into a pre-chilled 2
296 mm electroporation cuvette (Cell Projects, Kent, England) and subjected to electroporation at
297 1.5 kV (*Lb. brevis*) or 2.0 kV (*L. lactis*), 200 Ω, 25 µF. Following electroporation, 950 µL
298 recovery broth was added (MRS broth supplemented with 0.5 M sucrose and 0.1 M $MgCl_2$
299 (*Lb. brevis*) or GM17 broth supplemented with 20 mM $MgCl_2$ and 2 mM $CaCl_2$ (*L. lactis*)).
300 Cells were recovered at 30 ˚C for 3 h (*Lb. brevis*) or 2 h (*L. lactis*) prior to spread plating on

301 MRS (*Lb. brevis*) or GM17 (*L. lactis*) agar supplemented with Cm5. Presumed transformants
302 were purified on MRS agar + Cm5 and colonies were checked by sequencing after PCR
303 amplification using the primers pnz44F and pnz44R (Table 2) and applied to growth assays
304 as described below.

305 *Growth assays*

306 Growth profiles of the wild-type strain and its derivative were obtained by transferring an
307 overnight culture (1 % inoculum) to MRS broth, MRS broth supplemented with 30 ppm *iso*-
308 α-acids or beer (fresh Heineken lager 5 % ethanol, pH 4, 23 ppm *iso*-α-acids). Cultures were
309 incubated at 30 ˚C for 72 hours. One mL of culture was retrieved after 24, 48, 72 and 96
310 hours, diluted in Ringer's solution and plated on MRS agar plates. Plates were incubated at
311 30 ˚C anaerobically for 48 hours prior to colony counting. The number of viable bacteria of
312 each strain was assessed after CFU/mL calculation. Non-inoculated controls were used in all
313 the experiments as blank measurements. These measurements were then subtracted from each
314 experimental condition to produce the values represented on growth curves. Statistical
315 differences were calculated using unpaired *t* test method (32).

316 *Phage activity against Lb. brevis strains and transformants*

317 To assess phage sensitivity of *Lb. brevis* strains, transformants carrying genes of interest were
318 compared to the wild-type (WT) strain using plaque assays, as previously described (33). A
319 10 µL volume of the appropriate phage dilution and 200 µL of *Lb. brevis* culture were added
320 to 4 mL of soft agar supplemented with 10 mM $CaCl_2$, mixed and poured onto an MRS agar
321 plate supplemented with 10 mM $CaCl_2$ and 0.5% glycine. Plates were incubated at 30 °C
322 overnight and the resulting plaques were enumerated. Phage titre was determined as plaque-
323 forming units per mL (PFU/mL). The ability of phages to propagate and multiply within the
324 host cell was also tested. *Lb. brevis* strains were grown to early exponential phase (OD_{600nm} ~

Accepted Manuscript Posted Online

325 0.25), at which point phages were added to the culture (T0) at a MOI (multiplicity of
326 infection) of 1, along with 10 mM $CaCl_2$. The mix was further incubated at 30 °C overnight
327 (T1). The number of phages present in the medium (i.e. following removal of bacterial cells
328 by centrifugation) at T1 was then determined by plaque assay. Phage propagation efficiency
329 on a given host was then determined by dividing the phage titre (PFU/mL) at T1 by the phage
330 titre (PFU/mL) at T0.

335 **Author Contributions:** MF performed experiments and genomic analysis. DS, JM, TS and
336 VB provided materials and strains. MF, JM, TS and DS were involved in project design and
337 wrote the manuscript. All authors read and approved the final manuscript.

338 **Conflicts of Interest:** The authors declare that VB and TS are employees of Heineken.

339 **Funding:** Marine Feyereisen is the recipient of an Irish Research Council Enterprise
340 Partnership Scheme postgraduate scholarship (Ref. No. EPSPG/2015/7). Douwe van
341 Sinderen is supported by a Principal Investigator award (Ref. No. 450 13/IA/1953) through
342 Science Foundation Ireland (SFI). Jennifer Mahony is in receipt of a Starting Investigator
343 Research Grant (SIRG) (Ref. No. 15/SIRG/3430) funded by Science Foundation Ireland
344 (SFI).
