# THE INDEPENDENCE NUMBER OF THE ORTHOGONALITY GRAPH IN DIMENSION $2^{k}$ 

FERDINAND IHRINGER AND HAJIME TANAKA

#### Abstract

We determine the independence number of the orthogonality graph on $2^{k}$-dimensional hypercubes. This answers a question by Galliard from 2001 which is motivated by a problem in quantum information theory. Our method is a modification of a rank argument due to Frankl who showed the analogous result for $4 p^{k}$-dimensional hypercubes, where $p$ is an odd prime.

## 1. Introduction

The orthogonality graph $\Omega_{n}$ has the elements of $\{-1,1\}^{n}$ as vertices, and two vertices are adjacent if they are orthogonal, in other words, if their Hamming distance is $n / 2$. The graph $\Omega_{n}$ occurs naturally when comparing classical and quantum communication [3]. In particular, for $n=2^{k}$ the cost of simulating a specific quantum entanglement on $k$ qubits can be reduced to determining the chromatic number $\chi\left(\Omega_{n}\right)$ of $\Omega_{n}$ [2, 9]. The graph $\Omega_{n}$ is edgeless if $n$ is odd, and is bipartite if $n \equiv 2(\bmod 4)$. For $n \equiv 0(\bmod 4)$, Frankl [7] and Galliard [9] constructed an independent set of $\Omega_{n}$ of size

$$
a_{n}:=4 \sum_{i=0}^{n / 4-1}\binom{n-1}{i},
$$

and Galliard [9] asked in 2001 if this is the independence number $\alpha\left(\Omega_{n}\right)$ of $\Omega_{n}$ when $n=2^{k}, k \geqslant 2$. Newman [15] and, according to [8, p. 275, Remark], Frankl conjectured that this holds whenever $n \equiv 0(\bmod 4)$. See also 4]. Frankl 7] already showed the conjecture in 1986 for all $n=4 p^{k}$ for $k \geqslant 1$, where $p$ is an odd prime. De Klerk and Pasechnik 13 proved the conjecture for $n=16$, i.e., that $\alpha\left(\Omega_{16}\right)=2304$, using Schrijver's semidefinite programming bound [16. Furthermore, Frankl and Rödl [8] showed that $\alpha\left(\Omega_{n}\right)<1.99^{n}$ if $n \equiv 0(\bmod 4)$. In this note, we apply Frankl's method from [7] to show the following:

Theorem. Let $n=2^{k}$ for some $k \geqslant 2$. Then $\alpha\left(\Omega_{n}\right)=a_{n}$.
Together with the discussion in [9, Section 5.5], that is using $\chi\left(\Omega_{n}\right) \geqslant 2^{n} / \alpha\left(\Omega_{n}\right)$, our result implies an explicit version of Theorem 4 in [2]. Finding such an explicit result is one motivation for Galliard's work. See also [10, 12 .

## 2. Proof of the Theorem

Let $A_{j}$ be the 0-1-matrix indexed by the vertices of the hypercube $Q_{n}=\{-1,1\}^{n}$ with $\left(A_{j}\right)_{x y}=1$ if $x$ and $y$ have Hamming distance $j$. The matrices $A_{j}$ have $n+1$ common eigenspaces $V_{0}, V_{1}, \ldots, V_{n}$, and in the usual ordering of the eigenspaces the eigenvalue of $A_{j}$ with respect to $V_{i}$ is given by the Krawtchouk polynomial (see [5], Theorem 4.2])

$$
K_{j}(i)=K_{j}(i ; n):=\sum_{h=0}^{j}(-1)^{h}\binom{i}{h}\binom{n-i}{j-h} .
$$

It is known that the orthogonal projection matrix $E_{i}$ onto $V_{i}$ has the entry $\left(E_{i}\right)_{x y}=$ $2^{-n} K_{i}(j)$ if $x$ and $y$ are at Hamming distance $j$ [5, Theorem 4.2], so that we have in particular rank $E_{i}=\operatorname{trace} E_{i}=K_{i}(0)=\binom{n}{i}$. The $(n+1)$-dimensional matrix algebra spanned by $A_{0}=I, A_{1}, \ldots, A_{n}$ is called the Bose-Mesner algebra of $Q_{n}$.

Assume now that $n=2^{k}, k \geqslant 3$. (The result is trivial if $k=2$.) Let $C$ be an independent set of $\Omega_{2^{k}}$, and let $C_{\text {even }}^{ \pm}, C_{\text {odd }}^{ \pm} \subseteq\{-1,1\}^{2^{k}-1}$ be as in [7]: $C_{\text {even }}^{+}$is given by taking all the even-weight elements of $C$ that end with +1 , followed by truncating at the last coordinate, and the other three are analogous. Let $C^{\prime}$ be one of these four families. Then the Hamming distances in $C^{\prime}$ are even and unequal to $2^{k-1}$, so they lie in the following set:

$$
\begin{equation*}
\left\{2 s: s=0,1, \ldots, 2^{k-1}-1, s \neq 2^{k-2}\right\} \tag{1}
\end{equation*}
$$

Below we work with the Bose-Mesner algebra $\mathscr{A}$ of $Q_{2^{k}-1}$. For every $M \in \mathscr{A}$, let $\bar{M}$ denote the principal submatrix corresponding to $C^{\prime}$. Consider the polynomial

$$
\varphi(\xi)=\binom{\xi / 2-1}{2^{k-2}-1} \in \mathbb{R}[\xi]
$$

and expand it in terms of the Krawtchouk polynomials $K_{i}(\xi)=K_{i}\left(\xi ; 2^{k}-1\right)$ :

$$
\begin{equation*}
\varphi(\xi)=\sum_{i=0}^{2^{k-2}-1} c_{i} K_{i}(\xi) \tag{2}
\end{equation*}
$$

Let

$$
X=\sum_{j=0}^{2^{k}-1} \varphi(j) A_{j} \in \mathscr{A}
$$

On the one hand, observe that $\bar{X}$ has only integral entries in view of 11 , and an easy application of Lucas' theorem (cf. [6]) shows moreover that $\bar{X} \equiv \bar{I}(\bmod 2)$. In particular, $\bar{X}$ is invertible. On the other hand, from $\sqrt{2}$ we have

$$
X=2^{2^{k}-1} \sum_{i=0}^{2^{k-2}-1} c_{i} E_{i}
$$

It follows that

$$
\left|C^{\prime}\right|=\operatorname{rank} \bar{X} \leqslant \operatorname{rank} X \leqslant \sum_{i=0}^{2^{k-2}-1} \operatorname{rank} E_{i}=\sum_{i=0}^{2^{k-2}-1}\binom{2^{k}-1}{i}
$$

As $|C|=\left|C_{\text {even }}^{+}\right|+\left|C_{\text {even }}^{-}\right|+\left|C_{\text {odd }}^{+}\right|+\left|C_{\text {odd }}^{-}\right|$, the theorem follows.

## 3. Future Work

Schrijver's semidefinite programming bound has been extended to hierarchies of upper bounds; see, e.g., [1, 14. In view of [13], it is interesting to investigate if these bounds in turn prove the conjecture for other values of $n$. One of the referees pointed out to us that using next level in the hierarchy, see [11, yields the correct bound of $a_{24}=178208$ for the case $n=24$.

Problem. Prove the conjecture for $n=40$, which is the first open case.
Acknowledgements. We thank the anonymous referee for solving the case $n=24$.
