ABSTRACT

Background: For patients with atrial fibrillation (AF), a comprehensive care approach based on the “Atrial fibrillation Better Care” (ABC) pathway can reduce the occurrence of adverse outcomes. The aim of this paper was to investigate if an approach based on the ABC pathway is associated with a reduced risk of adverse events in ‘clinically complex’ AF patients, including those with multiple co-morbidities, polypharmacy and prior hospitalizations.

Methods and Results: We performed a post-hoc analysis of the Atrial Fibrillation Follow-up Investigation of Rhythm Management (AFFIRM) trial. The principal outcome was the composite of all-cause hospitalization and all-cause death. An integrated care approach (ABC group) was used in 3.8%, 4.0% and 4.8% in multimorbidity, polypharmacy and hospitalized groups, respectively. In all ‘clinically complex’ groups, the cumulative risk of the composite outcome was significantly lower in patients managed consistent with the ABC pathway vs. non-ABC pathway-adherent (all $p < 0.05$). Cox regression analysis showed a reduction of composite outcomes in ABC pathway-adherent vs. non-ABC pathway-adherent for multimorbidity (hazard ratio [HR]: 0.61, 95% confidence interval [CI]: 0.44-0.85), polypharmacy (HR: 0.68, 95% CI: 0.47-1.00) and hospitalization (HR: 0.59, 95% CI: 0.42-0.85) groups. Secondary analyses showed that the higher number of ABC criteria fulfilled the larger associated reduction in relative risk, even for secondary outcomes considered.

Conclusions: Use of an ABC consistent pathway is associated with fewer major adverse events in patients with AF who have multiple co-morbidities, use of polypharmacy and prior hospitalization.

CLINICAL PERSPECTIVE

What is new?

- In this post-hoc analysis, we demonstrated that in clinically complex atrial fibrillation (AF) patients (i.e. those presenting with multimorbidity, polypharmacy and presenting with a recent hospitalization), a clinical management adherent to the 'Atrial fibrillation Better Care' (ABC) pathway, an approach to streamline the integrated care in AF, is associated with a reduction in major adverse events risk.

What are the clinical implications?

- In high-risk group of AF patients, such as those more clinically complex, the application of a more integrated, holistic, clinical approach that would take account of all the aspects related to the general and specific management of the disease would entail a significant and substantial reduction of all major adverse outcomes.

ABC= Atrial Fibrillation Better Care

AFFIRM= Atrial Fibrillation Follow-up Investigation of Rhythm Management r

INTRODUCTION

Patients affected with atrial fibrillation (AF) are at high risk for cardiovascular and non-cardiovascular death¹⁻⁶. This risk is associated with multiple co-morbidities^{7,8}, polypharmacy^{6,9,10} and prior hospitalization^{11,12}, all features that characterize the 'clinically complex' patient.

Evidence has emerged indicating that an integrated or holistic management approach in patients with AF can reduce mortality associated with AF¹³. These data, together with the need to reduce major adverse events in AF patients beyond just the risk of ischemic stroke, has inspired new thinking regarding a multifaceted approach to AF management¹⁴⁻¹⁶. The Atrial fibrillation Better Care (ABC) pathway has been proposed to streamline implementation of an integrated approach to managing patients with AF¹⁶.

The ABC pathway has three main pillars: '**A**' Avoid stroke (with **A**nticoagulants); '**B**' **B**etter symptom management, with patient-centred decisions on rate or rhythm control; '**C**' **C**ardiovascular and **C**omorbidity risk optimisation¹⁶. Thus far, retrospective analyses have shown that management resembling the ABC pathway has been associated with reduction in AF-related clinical outcomes¹⁷⁻¹⁹. In a post-hoc analysis derived from the Atrial Fibrillation Follow-up Investigation of Rhythm Management (AFFIRM) trial, we previously showed how a clinical approach based on ABC pathway was associated with reduction in risk for major bleeding, all-cause death, cardiovascular (CV) death, first hospitalization, first CV hospitalization and multiple hospitalizations¹⁷.

Here, we investigate if an approach based on the ABC pathway is associated with reduced risk of adverse events in three prespecified subgroups of 'clinically complex' AF patients at high risk for all-cause death and other adverse outcomes, including those with multiple co-morbidities, those taking multiple drugs (polypharmacy) and those hospitalized when AF was diagnosed.

METHODS

The authors declare that all supporting data and methods used to derive the results and the related findings are available within the article.

We considered patients enrolled in the AFFIRM trial^{20,21}. The AFFIRM trial was approved by the University of Missouri Institutional Review Board (IRB); the database was obtained from the National Institute of Health. The IRB for every participating centre approved the study protocol and all patients entered the study after providing written informed consent. The study was performed according to the EU Note for Guidance on Good Clinical Practice CPMP/ECH/135/95 and the Declaration of Helsinki.

Implementation of the ABC pathway in the AFFIRM trial cohort has been described in detail elsewhere¹⁷. In brief, the 'A' criterion was fulfilled if the patient had a time in therapeutic range $\geq 70\%$; the 'B' criterion was fulfilled if the patient presented with 2 or less symptoms; the 'C' criterion was fulfilled if the patient were properly managed for the concomitant CV comorbidities (hypertension, coronary artery disease, peripheral artery disease, previous stroke/transient ischemic attack, heart failure)¹⁷.

We defined three groups of 'clinically complex' patients, deemed at high risk for adverse AF-related outcomes: i) **Multimorbidity group**: if the patient had two or more concomitant conditions²², among the 11 listed in the AFFIRM case report form (myocardial infarction, heart failure, hypertension, cardiomyopathy, valvular heart disease, congenital heart disease, previous stroke/transient ischemic attack, peripheral arterial disease, diabetes, hepatic/renal disease, pulmonary disease); ii) **Polypharmacy group**: if the patient used 5 or more drugs, as reported in a previous paper from the same cohort⁶; iii) **Hospitalization group**: if the patient was hospitalized at the time of the index AF event, as was originally included in the AFFIRM study.

Study Outcomes

The primary outcome considered was a composite of all-cause hospitalization and all-cause death. We separately considered all-cause hospitalization and all-cause death as independent outcomes. We also considered occurrence of cardiovascular events, defined as stroke, major bleeding, CV hospitalization or CV death, as additional outcomes. Finally, we considered occurrence of any clinical event among those described above as a study outcome. All the specific clinical events (i.e. not those composite) were adjudicated centrally, according to the original study protocol²⁰.

Statistical Analysis

All continuous variables were reported as median and interquartile range (IQR). Categorical variables were expressed as counts and percentages and compared using the chi-square test.

Cumulative incidence of adverse events is shown using Kaplan-Meier curves, and compared across the groups with the Log-Rank test. Cox regression was used to assess the association between the use of integrated care adherent to the ABC pathway and the occurrence of outcomes. Covariates considered for adjustment were age, sex, diabetes mellitus, hepatic/renal disease, pulmonary disease, first AF episode, and use of aspirin, and were implemented in the various models as reported specifically in the Tables and Figures.

The main analyses included comparisons between the ABC pathway consistent group vs. the non-ABC pathway group. A secondary analysis examined the relationship between the total number of ABC pathway criteria fulfilled and occurrence of the study outcomes. Finally, a sensitivity analysis examined the degree of overlap between the three subgroups and the impact of the ABC adherent management. A two-sided p-value <0.05 was considered statistically significant. All analyses were performed using SPSS v. 25.0 (IBM, NY, USA).

RESULTS

From the original AFFIRM cohort, a total of 3169 (78.0%) patients were available for this analysis¹⁷. Baseline characteristics of this cohort are reported in Table 1. Median [IQR] age was 70 [65-76] years, 1237 (39.0%) were female, median [IQR] CHA₂DS₂-VASc score was 3 [2-4] and median [IQR] time in therapeutic range was 67.9% (51.5-81.0%). Of this cohort, 222 (7.0%) were managed consistent with the ABC pathway¹⁷.

The multimorbidity group comprised 1723 (54.4%) patients, while 1222 (38.6%) were included in the polypharmacy group and 1360 (42.9%) in the hospitalization group. Baseline characteristics for the three groups were summarised in Table 1. Median age was similar between the groups, with a slightly lower prevalence of females in the multimorbidity group. CHA₂DS₂-VASc score was numerically higher in the multimorbidity group compared to the overall cohort and the other subgroups. ABC pathway consistent management was found in 66 (3.8%) in the multimorbidity group, 49 (4.0%) in the polypharmacy group and in 65 (4.8%) for the hospitalization group.

Follow-Up Analysis

In the multimorbidity group, after a median [IQR] 3.63 [2.73-4.54] years of follow-up, there were 1238 composite outcome events (37.8 per 100 patient-years), 1185 hospitalization events (36.2 per 100 patient-years), 262 all-cause death (4.21 per 100 patient-years), 855 cardiovascular events (20.3 per 100 patient-years) and a total of 1245 'any event' outcomes (38.3 per 100 patient-years). Event rates for the non-ABC group was significantly higher than the ABC group for all outcomes considered [Figure 1, Panel A].

In the polypharmacy group, after a median [IQR] 3.59 [2.73-4.49] years of follow-up, a similar rate of events was evident, except for all-cause death which was numerically lower than in the multimorbidity group. There were 865 composite outcome events (37.7 per 100 patient-years), 833 hospitalizations (36.3 per 100 patient-years), 165 deaths (3.76 per 100 patient-years), 599 cardiovascular events (20.5 per 100 patient-years) and a total of 870 'any event' outcomes (38.4 per 100 patient-years). The overall rate of outcomes was higher in non-ABC pathway-

adherent group than in ABC pathway-adherent group (see Figure 1 Legend), except for all-cause death ($p=0.123$) [Figure 1, Panel B].

A similar rate of events was reported in the hospitalization group, with 967 composite outcome events (37.0 per 100 patient-years), 929 recurrent hospitalization (35.5 per 100 patient-years), 187 deaths (3.66 per 100 patient-years), 687 cardiovascular events (20.7 per 100 patient-years) and a total of 972 'any event' outcomes (37.5 per 100 patient-years). Similar to the results from the other two groups, non-ABC pathway adherent patients reported a higher rate of all outcomes under consideration (all $p<0.001$), except for all-cause death; mortality was numerically lower but did not reach statistical significance ($p=0.068$) [Figure 1, Panel C].

Kaplan-Meier curves for the composite outcome showed that patients managed with ABC pathway-adherent care had a lower cumulative risk in all 3 'clinically complex' patient groups [Figure 2, Panels A, B, C].

Cox Regression Analysis

A Cox regression analysis was performed (Table 2). In the multimorbidity group, ABC clinical management was associated with a reduction in risk for the composite outcome (hazard ratio [HR]: 0.61, 95% confidence interval [CI]: 0.44-0.85, $p=0.004$), with a significant reduction in relative risk for all the other outcomes considered, in particular, for all-cause death (HR: 0.23, 95% CI: 0.06-0.94, $p=0.041$) (Table 2).

In the polypharmacy group, adjusted risk reduction for the composite outcome approached statistical significance (HR: 0.68, 95% CI: 0.47-1.00, $p=0.053$) (Table 2).

A reduction in risk was found for any event outcome (HR: 0.68, 95% CI: 0.46-0.99, $p=0.045$), but no significant difference was found for all-cause death (Table 2).

Results similar to those in the multimorbidity group were observed for patients hospitalized at the time of the index event, with a significant reduction in the risk of the composite outcome and other secondary outcomes, but no significant difference in the risk of all-cause death was found (Table 2).

Secondary Analyses

A secondary analysis was performed to compare the number of ABC pathway criteria fulfilled vs. no ABC pathway criteria fulfilled [Figure 3]. In the multimorbidity group, there was a progressively lower risk of outcomes according to the increasing number of ABC criteria fulfilled [Figure 3, Panel A], with the higher risk reduction obtained when all 3 ABC criteria are fulfilled compared to no ABC criteria.

In the polypharmacy group a similar relationship between the number of ABC criteria and occurrence of outcomes was found, albeit with a slightly lower magnitude than in the multimorbidity group [Figure 3, Panel B]. For the occurrence of the all-cause death, a significant reduction in risk was associated with 1 ABC criterion (HR: 0.68, 95% CI: 0.48-0.94) or 2 ABC criteria fulfilled (HR: 0.51, 95% CI: 0.31-0.83), however, when all 3 ABC criteria were fulfilled there was a non-statistically significant reduction, with wide 95%CI (HR: 0.36, 95% CI: 0.12-1.18) [Figure 3, Panel B].

In the hospitalization group, a similar reduction in the risk of major adverse events was evident with an increasing number of ABC criteria fulfilled, with the strongest

reduction in risk for the composite outcome when all 3 ABC criteria were fulfilled (HR: 0.45, 95% CI: 0.31-0.65). In all three “clinically complex” patients’ subgroups, increasing number of ABC pathway criteria fulfilled were associated with a progressively lower risk for the occurrence of ‘any event’, with the exception of the outcome of all-cause death in the polypharmacy group.

Sensitivity Analysis

We examined how much the three subgroups overlapped and what was the impact of ABC adherent management in reducing the occurrence of outcomes. Among the 3169 patients included in this analysis, only 740 (23.4%) were not included in any of the 3 clinically complex subgroups, while among the remaining 2429 patients, 1058 (43.6%) were included in only one subgroup, 866 (35.7%) were included in two subgroups and 493 (20.8%) were included in all 3 subgroups.

The prevalence of ABC pathway adherent group decreased progressively from those included in only one subgroup to those included in all the 3 subgroups (7.4% vs. 3.8% vs. 2.4%, $p < 0.001$). Given the low numbers, we only considered the occurrence of the primary outcome. Among those included in ≥ 2 subgroups, patients managed adherent to ABC pathway had a lower rate of composite outcome (57.8% vs. non-ABC adherent, 74.0%; $p = 0.015$). After adjustment, the Cox regression analysis demonstrated that ABC pathway adherence among those included in ≥ 2 subgroups was associated to a lower risk of the primary outcome (HR: 0.60, 95% CI: 0.44-0.96).

DISCUSSION

In this post-hoc subgroup analysis derived from the AFFIRM trial, we showed that in clinically complex patient subgroups (i.e. multimorbidity, polypharmacy, hospitalization), management with an approach consistent with the one proposed by the ABC pathway, that streamline the approach to AF patients care, was associated with reduction in the composite outcome of all-cause hospitalization and all-cause death in all the three groups considered. Management consistent with the ABC pathway was associated with reduction of 'any event' outcome for those clinical events considered. Further, an increasing number of ABC criteria fulfilled was associated with a progressively larger reduction in risk for most of the outcomes considered. Lastly, even amongst patients having ≥ 2 clinical complex characteristics, the adherence to ABC pathway is still associated with a lower risk of the composite outcome, reinforcing the separate evidence coming from the 3 clinical subgroups.

The impact of the three clinical subgroups (i.e. multimorbidity, polypharmacy, hospitalization) in determining an increased risk in major adverse events have been previously described^{6-12,23}. For the presence of multimorbidity, several observational and randomized controlled trials have shown an increased risk for all major adverse events relevant to AF patients, in particular all-cause death^{7,8,23}. Similarly, an increased risk of cardiovascular events and death is evident for AF patients reporting polypharmacy^{6,9,10} and an increased risk of death in hospitalized AF patients^{11,12} were reported. In all these conditions, an increased rate of events was described, with an increased association with risk of events that was found to be independent of other clinical characteristics. Given the increased complexity and the higher risk of major adverse events in those with the described clinical features, an approach

consistent with the ABC pathway may be beneficial. Indeed, a large group of patients were included in at least two of the subgroups and hence, had even greater clinical complexity.

Streamlining decision-making to facilitate management of clinically complex patients with AF starting with primary care and linking with secondary care (including cardiologist and non-cardiologists) may improve outcomes. The ABC pathway has been proposed as a simple and pragmatic approach to streamline and integrate care¹⁶. Thus far, the ABC pathway has been tested indirectly, but it appears to reduce major adverse events in patients with AF¹⁷⁻¹⁹. Prior studies have assessed several clinical settings and patients' characteristics including the overall AFFIRM cohort¹⁷⁻¹⁹.

In our study, together with the previous analysis on the ABC pathway in AFFIRM¹⁷, we found a low percentage of patients treated as fully adherent to the ABC pathway compared to other studies^{18,19}. In a prospective Italian observational cohort, for example, management adherent with the ABC pathway was associated with a 56% risk reduction for a composite outcome of cardiovascular events¹⁸. Similarly, in a population-based nationwide cohort, there was a significant reduction (~15%) in all adverse outcomes with ABC pathway-adherent management¹⁹. Considering the time of the AFFIRM study enrollment (>15 years ago), it is possible that a clinical management based on a single-disease approach was more common in the past, compared to current practice, which holistic and integrated management is more used.

In the present post-hoc analysis, even in high risk subgroups, where the risk of adverse events is high, use of an ABC pathway approach was associated with fewer AF-related outcomes. The adjudicated outcomes of hospitalization and all-cause death were reduced in all three subgroups. The risk for hospitalization (considered as a single outcome) was also reduced with similar magnitude. Nonetheless, we may be underpowered to assess reduction in all-cause death in the polypharmacy and hospitalization groups.

Our secondary analysis showed that risk was progressively lowered with a progressively higher numbers of ABC criteria fulfilled. This trend was also evident for all-cause death in the polypharmacy and hospitalization groups. However, the low number of events in the fully ABC pathway-adherent group is a limitation; however, the consistency of results in the patients with even higher clinical complexity reinforces the idea that more complex patient is much more likely to get a beneficial effect from a comprehensive and integrated approach to AF care. Indeed, utilization of the ABC pathway was associated with reduction in 'any clinical event' amongst these clinically complex patients further emphasizes the importance of improving the overall management of AF patients comprehensively, beyond thromboembolic risk²⁴.

Limitations

The post-hoc nature, the modest number of subjects in the ABC compliant groups compared to the overall cohort (which limits the reliability of Kaplan-Meier analysis) and the relatively aged dataset are limitations to this analysis. Since the AFFIRM study is an old clinical trial, this could limit the generalizability of our results, given the changes in AF management practices that have occurred in the last 15 years.

Also, other general management aspects of AF patients (such as weight management, evaluation/management of sleep apnoea, etc) were not routinely assessed at the time of the AFFIRM study and were not reported in the trial dataset. The AFFIRM trial compared rhythm vs rate) control, but this was not the objective of the present study which focused on 'better symptom' management overall (even within the heart failure subgroup, where rhythm control with catheter ablation has been beneficial compared to only drug therapy²⁵). Nonetheless, we believe that the AFFIRM study design, which included patients with significant risk factors, still gives a good representation of the 'typical' AF population.

Conversely, the adjudicated outcomes and the largely proved reliability of the AFFIRM database makes this *hypothesis generating* analysis reliable. Indeed, these results, supported by previous evidence, encourages use of an ABC pathway-adherent approach, to streamline and integrate care in clinically complex patients with AF.

CONCLUSION

Management of AF by an ABC consistent pathway is associated with reduction in major adverse events in clinically complex AF patients, including those with multimorbidity, polypharmacy and prior hospitalization. These exploratory findings need further confirmation in larger, more contemporary studies.
