Abstract. According to the walking character of lower extremity power-assisted exoskeleton that was designed by our Robotics Laboratory, D-H convention was applied to the kinematics analysis of this exoskeleton model. Lagrangian dynamics was used to analyzing dynamics for the single-foot support model, double-feet support model and double-feet support with one redundancy model respectively. The kinematical equation was obtained and MATLAB was used to verify its validity. Meanwhile, the kinetic equations and torque of each joint were obtained by virtue of ADAMS. Our study provided a theoretical foundation for the control strategies, and optimization design of the mechanical structure and promoted the practical application of this lower extremity power-assisted exoskeleton in further research.

Keywords: lower exoskeleton, dynamic, kinematics, simulation.

1. Introduction

Lower extremity power-assisted exoskeleton is a kind of robot which is defined as an electromechanical device in overall or a frame that worn by a human operator. The lower extremity power-assisted exoskeleton is developed mainly to help human perform difficult tasks due to either their physical limitations or muscles' fatigues. In addition, exoskeletons can increase the endurance, traveling speed, and even balance of the wearer in extremely difficult terrains [1]. With the development of science and technology, the research on lower extremity exoskeleton has gradually extended to the field of mechanics, robotics, bionics, control theory, information processing, and communication technology etc.

As early as in 1960s, our pioneers have started to research on the exoskeleton. A master-slave system named the Hardiman was developed by General Electric in 1968. Furthermore some successful and remarkable examples of lower extremity power-assisted exoskeleton such as BLEEX and HAL, were designed for military missions and power enhancement respectively in the 21st century [2].

The Berkeley Lower Extremity Exoskeleton (BLEEX) project funded by the Defense Advanced Research Project Agency (DARPA), USA, was first unveiled in 2004, at the University of California, Berkeley's Human Engineering and Robotics Laboratory [3]. It was a field-operational robotic system worn by an operator, which could provide the wearer with the ability of undertaking significant loads on the back with minimal effort when negotiating any terrain. BLEEX featured seven DOFs per leg, and the exoskeleton was actuated via bidirectional linear hydraulic cylinders mounted in a triangular configuration with the rotary joints, resulting in an effective moment arm varying with joint angles [4].

Hybrid Assistive Limb (HAL) was successfully developed in Tsukuba University of Japan which was a lightweight power assist device. The latest model, HAL-5, was a full-body suit unit designed to aid people who had degenerated muscles and paraplegics from brain or spinal injuries. It was connected to thighs and shanks of the patient and moved the patient's legs as a function of the EMG (electromyogram) signals measured from the wearer [4]. Through the use of DC motors integrated with harmonic drives, each leg of HAL-5 powers the flexion/extension motion at the hip and knee in the sagittal plane.

The lower extremity power-assisted exoskeleton system (LEPES) designed by our Robotics

Laboratory is a kind of wearable mechanical legs, which contains mechanical systems, sensors and control systems. The mechanical system includes waist, hip, knee, leg and foot. In regardless of complex activities such as jumping and going-upstairs, the main purpose of LEPES is providing power assistance for wearers when they walk hard. Thus, in the aspect of DOFs' distribution, the LEPES features three DOFs at the hip, one at the knee, and three at the ankle per leg. Of these, two DOFs are actuated by Maxon DC motors: hip flexion/extension and knee flexion/extension in the sagittal plane. The mechanical structure built in our Robotics Laboratory is shown in Fig. 1.

As a wearable biped exoskeleton system, LEPES should be programmed to walk naturally to provide intimacy to human. However, the human gait is a complex dynamic activity. Therefore, in order to get accurate control strategies and conduct the optimization design of mechanical structure, it is very important and necessary to build the dynamic and kinematics model and gain the kinematical and dynamic equation for LEPES.

Fig. 1. The lower extremity power-assisted exoskeleton system

Fig. 2. Kinematical model of LEPES

2. Kinematical model of LEPES

The kinematic analysis of LEPES can be facilitated by using the Denavit-Hartenberg (D-H) convention because of its well-established analysis procedures.

In order to simplify the calculation of the kinematical model, the waist (actually the projection of waist in the sagittal plane), the legs and the feet are regarded as the rigid links; the hip, knee and ankle are simplified as the revolute pair in the sagittal plane. Thus, the whole kinematical model is a five-link biped model, and the link frames {0} through {6} of the LEPES can be established, as shown in Fig. 2. Here, frame {0} represents the world reference frame, where x_0 is horizontal axis, y_0 is vertical axis and z_0 is perpendicular to the surface with the outward direction as the positive direction.

Based on the D-H rules and the five-link biped model, parameters of LEPES can be deduced as shown in Table 1. It should be noted that the parameters in Table 1 can be selected in different ways because the D-H notation is not unique.

According to the D-H convention, D-H homogeneous matrix representation is used to describe the spatial displacement between neighboring link coordinate frames to obtain the information related to kinematics of each link [5].

Assuming ${}^{i-1}M_i$ is the homogeneous transformation matrix describing the relative translation and rotation between l_{i-1} and l_i coordinate systems, then we can obtain:

$${}^0M_1 = \begin{bmatrix} c\theta_1 & -s\theta_1 & 0 & 0 \\ s\theta_1 & c\theta_1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{1}$$

$${}^1M_2 = \begin{bmatrix} c\theta_2 & -s\theta_2 & 0 & l_1 \\ s\theta_2 & c\theta_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{2}$$

$${}^2M_3 = \begin{bmatrix} c\theta_3 & -s\theta_3 & 0 & l_2 \\ s\theta_3 & c\theta_3 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{3}$$

$${}^3M_4 = \begin{bmatrix} c\theta_4 & -s\theta_4 & 0 & l_3 \\ s\theta_4 & c\theta_4 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{4}$$

$${}^4M_5 = \begin{bmatrix} c\theta_5 & -s\theta_5 & 0 & l_4 \\ s\theta_5 & c\theta_5 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{5}$$

$${}^5M_6 = \begin{bmatrix} c\theta_6 & -s\theta_6 & 0 & l_5 \\ s\theta_6 & c\theta_6 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{6}$$

where sin and cos are represented by s and c, respectively.

Table 1. D-H parameters for LEPES

i	l_{i-1}	α_{i-1}	d_{i-1}	θ_{i-1}	q_i
0	0	0	0	θ_1	θ_1
1	l_1	0	0	θ_2	θ_2
2	l_2	0	0	θ_3	θ_3
3	l_3	0	0	θ_4	θ_3
4	l_4	0	0	θ_5	θ_5
5	l_5	0	0	θ_6	θ_6

Note: i is the link number,
 l_{i-1} is the distance between z_{i-1} and z_i along x_i ,
 α_{i-1} is the angle between z_{i-1} and z_i about x_i ,
 d_{i-1} is the distance between x_{i-1} and x_i along z_{i-1} ,
 θ_i is the angle between x_{i-1} and x_i about z_{i-1} ,
 q_i is the joint variable about l_i .

Thus, the ankle reference frame {6} can be expressed in the world reference frame {0}, as given in Eq. (7):

$${}^0M_6 = {}^0M_1 {}^1M_2 {}^2M_3 {}^3M_4 {}^4M_5 {}^5M_6 = \begin{bmatrix} c \sum_{j=1}^6 \theta_j & -s \sum_{j=1}^6 \theta_j & 0 & l_5 c \sum_{j=1}^5 \theta_j + l_4 c \sum_{j=1}^4 \theta_j + l_3 c \sum_{j=1}^3 \theta_j + l_2 c \sum_{j=1}^2 \theta_j + l_1 c \theta_1 \\ s \sum_{j=1}^6 \theta_j & c \sum_{j=1}^6 \theta_j & 0 & l_5 s \sum_{j=1}^5 \theta_j + l_4 s \sum_{j=1}^4 \theta_j + l_3 s \sum_{j=1}^3 \theta_j + l_2 s \sum_{j=1}^2 \theta_j + l_1 s \theta_1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{7}$$

According to D-H convention, Eq. (7) can be transformed as follows:

$$\begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} c \sum_{j=1}^6 \theta_j & -s \sum_{j=1}^6 \theta_j & 0 & l_5 c \sum_{j=1}^5 \theta_j + l_4 c \sum_{j=1}^4 \theta_j + l_3 c \sum_{j=1}^3 \theta_j + l_2 c \sum_{j=1}^2 \theta_j + l_1 c \theta_1 \\ s \sum_{j=1}^6 \theta_j & c \sum_{j=1}^6 \theta_j & 0 & l_5 s \sum_{j=1}^5 \theta_j + l_4 s \sum_{j=1}^4 \theta_j + l_3 s \sum_{j=1}^3 \theta_j + l_2 s \sum_{j=1}^2 \theta_j + l_1 s \theta_1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (8)$$

Thus, the position of the ankle 0p_6 can be determined as Eq. (9) with respect to the world reference frame $\{0\}$:

$${}^0p_6 = \begin{bmatrix} l_5 c \sum_{j=1}^5 \theta_j + l_4 c \sum_{j=1}^4 \theta_j + l_3 c \sum_{j=1}^3 \theta_j + l_2 c \sum_{j=1}^2 \theta_j + l_1 c \theta_1 \\ l_5 s \sum_{j=1}^5 \theta_j + l_4 s \sum_{j=1}^4 \theta_j + l_3 s \sum_{j=1}^3 \theta_j + l_2 s \sum_{j=1}^2 \theta_j + l_1 s \theta_1 \\ 0 \end{bmatrix} \quad (9)$$

The posture of the ankle 0R_6 can be determined as Eq. (10):

$${}^0R_6 = \begin{bmatrix} c \sum_{j=1}^6 \theta_j & -s \sum_{j=1}^6 \theta_j & 0 \\ s \sum_{j=1}^6 \theta_j & c \sum_{j=1}^6 \theta_j & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (10)$$

3. Dynamic models of LEPES

A human walking gait cycle can be divided into three gait patterns [6]: the single-foot support model(one foot stance, the other swing), double-feet support model(double feet whole stance) and double-feet support with one redundancy model(one foot whole stance while the heel or the toes of the other kicks the ground).

Since the force and the position of center of mass for each leg and each joint are different in each gait pattern, this paper decides to use Lagrangian method to analyze the three gait patterns respectively.

In order to simplify the calculation of the dynamic model, the waist (actually the projection of waist in the sagittal plane), the legs and the feet are regarded as the rigid links; the hip, knee and ankle is simplified as the revolute pair in the sagittal plane.

3.1. The double-feet support model

The double-feet support dynamic model of LEPES is illustrated in Fig. 3, where α_i stands for the distance between the center of mass of link i and the ends of link i ; θ_i represents the angle between link i and link $i - 1$; l_i is the length of each link; and m_i is the mass of each link i , $i = 1, 2, \dots, 6$; B_1 and B_2 represent the DC motors of knee, F_1 and F_2 stands for the DC motors of hip. Coordinate system $\{xoy\}$ is the world reference frame.

Thus, $G_i(x_i, y_i)$ (the center of mass of link i) can be obtained according to the geometric relationships in Fig. 3:

$$\begin{cases} x_0 = a_0, \\ x_1 = a_1 s \theta_1, \\ x_2 = l_1 s \theta_1 + a_2 s(\theta_1 - \theta_2), \\ x_3 = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + a_3 s(\theta_3 - \theta_1 + \theta_2), \\ x_4 = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + a_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4), \\ x_5 = \left\{ l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + \right. \\ \left. + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4) + a_5 s(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) \right\}, \\ x_6 = \left\{ l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + \right. \\ \left. + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 s(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) + a_6 \right\}, \end{cases} \quad (11)$$

$$\begin{cases} y_0 = 0, \\ y_1 = a_1 c \theta_1, \\ y_2 = l_1 c \theta_1 + a_2 c(\theta_1 - \theta_2), \\ y_3 = l_1 c \theta_1 + l_2 c(\theta_1 - \theta_2) - a_3 c(\theta_3 - \theta_1 + \theta_2), \\ y_4 = l_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) - a_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_5 = l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) - a_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_6 = 0. \end{cases} \quad (12)$$

The coordinate of each actuated motor $D_i(x_i, y_i)$ is:

$$\begin{cases} x_{B_1} = l_1 s \theta_1, \\ x_{F_1} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2), \\ x_{F_2} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2), \\ x_{B_2} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4), \end{cases} \quad (13)$$

$$\begin{cases} y_{B_1} = l_1 c \theta_1, \\ y_{F_1} = l_1 c \theta_1 + l_2 c(\theta_1 - \theta_2), \\ y_{F_2} = l_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_{B_2} = l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5). \end{cases} \quad (14)$$

Fig. 3. The double-feet support model

Fig. 4. The double-feet support with one redundancy (toes of one foot kicking the ground)

3.2. The double-feet support with one redundancy model

As mentioned above, there are two situations of the double-feet support with one redundancy model, and this study just analyzes the model that one foot whole stances while the toes of the other kick the ground because of the same theories, as shown in Fig. 4.

α_i stands for the distance between the center of mass of link i and the ends of link i ; θ_i represents the angle between link i and link $i - 1$; l_i is the length of each link; m_i is the mass of each link i , $i = 1, 2, \dots, 6$; B_1 and B_2 represent the DC motors of knee, F_1 and F_2 stands for the DC motors of hip. Coordinate system $\{xoy\}$ is the world reference frame.

Therefore, $G_i(x_i, y_i)$ (the center of mass of link i) can be obtained according to the geometric relationships:

$$\begin{cases} x_0 = l_0 s \theta_0 - a_0 s \theta_0, \\ x_1 = a_1 s \theta_1, \\ x_2 = l_1 s \theta_1 + a_2 s (\theta_1 - \theta_2), \\ x_3 = l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + a_3 s (\theta_3 - \theta_1 + \theta_2), \\ x_4 = l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + l_3 s (\theta_3 - \theta_1 + \theta_2) + a_4 s (\theta_3 - \theta_1 + \theta_2 - \theta_4), \\ x_5 = \left\{ \begin{array}{l} l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + l_3 s (\theta_3 - \theta_1 + \theta_2) + l_4 s (\theta_3 - \theta_1 + \theta_2 - \theta_4) + \\ + a_5 s (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) \end{array} \right\}, \\ x_6 = \left\{ \begin{array}{l} l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + l_3 s (\theta_3 - \theta_1 + \theta_2) + l_4 s (\theta_3 - \theta_1 + \theta_2 - \theta_4) + \\ + l_5 s (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) + a_6 \end{array} \right\}, \end{cases} \quad (15)$$

$$\begin{cases} y_0 = a_0 c \theta_0, \\ y_1 = a_1 c \theta_1 + l_0 c \theta_0, \\ y_2 = l_1 c \theta_1 + a_2 c (\theta_1 - \theta_2) + l_0 c \theta_0, \\ y_3 = l_1 c \theta_1 + l_2 c (\theta_1 - \theta_2) - a_3 c (\theta_3 - \theta_1 + \theta_2) + l_0 c \theta_0, \\ y_4 = l_4 c (\theta_3 - \theta_1 + \theta_2 - \theta_4) - a_4 c (\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_5 = l_5 c (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) - a_5 c (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_6 = 0. \end{cases} \quad (16)$$

The coordinate of each actuated motor $D_i(x_i, y_i)$ is:

$$\begin{cases} x_{B_1} = l_1 s \theta, \\ x_{F_1} = l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2), \\ x_{F_2} = l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + l_3 s (\theta_3 - \theta_1 + \theta_2), \\ x_{B_2} = l_1 s \theta_1 + l_2 s (\theta_1 - \theta_2) + l_3 s (\theta_3 - \theta_1 + \theta_2) + l_4 s (\theta_3 - \theta_1 + \theta_2 - \theta_4), \end{cases} \quad (17)$$

$$\begin{cases} y_{B_1} = l_1 c \theta_1 + l_0 c \theta_0, \\ y_{F_1} = l_1 c \theta_1 + l_2 c (\theta_1 - \theta_2) + l_0 c \theta_0, \\ y_{F_2} = l_4 c (\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_{B_2} = l_5 c (\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5). \end{cases} \quad (18)$$

3.3. The single-foot support model

Fig. 5 shows the single-foot support dynamic model of LEPES. α_i stands for the distance between the center of mass of link i and the ends of link i ; θ_i represents the angle between link i and link $i - 1$; l_i is the length of each link; m_i is the mass of each link i , $i = 1, 2, \dots, 6$; B_1 and B_2 represent the DC motors of knee, F_1 and F_2 stands for the DC motors of hip. Coordinate system $\{xoy\}$ is the world reference frame.

Thus, $G_i(x_i, y_i)$ (the center of mass of link i) can be obtained according to the geometric relationships:

$$\begin{cases} x_0 = l_0 s \theta_0 - a_0 s \theta_0, \\ x_1 = a_1 s \theta_1, \\ x_2 = l_1 s \theta_1 + a_2 s(\theta_1 - \theta_2), \\ x_3 = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + a_3 s(\theta_3 - \theta_1 + \theta_2), \\ x_4 = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + a_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4), \\ x_5 = \left\{ \begin{aligned} & l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4) + \\ & + a_5 s(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) \end{aligned} \right\}, \\ x_6 = \left\{ \begin{aligned} & l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4) + \\ & + l_5 s(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) + a_6 \end{aligned} \right\}, \end{cases} \quad (19)$$

$$\begin{cases} y_0 = a_0 c \theta_0 + h, \\ y_1 = a_1 c \theta_1 + l_0 c \theta_0 + h, \\ y_2 = l_1 c \theta_1 + a_2 c(\theta_1 - \theta_2) + l_0 c \theta_0 + h, \\ y_3 = l_1 c \theta_1 + l_2 c(\theta_1 - \theta_2) - a_3 c(\theta_3 - \theta_1 + \theta_2) + l_0 c \theta_0 + h, \\ y_4 = l_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) - a_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_5 = l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5) - a_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_6 = 0. \end{cases} \quad (20)$$

Fig. 5. The single-foot support model

The coordinate of each actuated motor $D_i(x_i, y_i)$ is:

$$\begin{cases} x_{B_1} = l_1 s \theta, \\ x_{F_1} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2), \\ x_{F_2} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2), \end{cases} \quad (21)$$

$$\begin{cases} x_{B_2} = l_1 s \theta_1 + l_2 s(\theta_1 - \theta_2) + l_3 s(\theta_3 - \theta_1 + \theta_2) + l_4 s(\theta_3 - \theta_1 + \theta_2 - \theta_4), \\ y_{B_1} = l_1 c \theta_1 + l_0 c \theta_0 + h, \\ y_{F_1} = l_1 c \theta_1 + l_2 c(\theta_1 - \theta_2) + l_0 c \theta_0 + h, \\ y_{F_2} = l_4 c(\theta_3 - \theta_1 + \theta_2 - \theta_4) + l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5), \\ y_{B_2} = l_5 c(\theta_3 - \theta_1 + \theta_2 - \theta_4 - \theta_5). \end{cases} \quad (22)$$

3.4. The equation of Lagrangian dynamics

According to the method of Lagrangian dynamics, the Lagrangian function is defined as the difference of the system between kinetic energy E_K and potential energy E_P , i.e.:

$$L = E_K - E_P. \quad (23)$$

The equation of Lagrangian dynamics can be obtained according to Eq. (23), as shown in Eq. (24):

$$Q_j = \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_j} \right) - \frac{\partial L}{\partial q_j}, \quad j = 0, 1, \dots, n, \quad (24)$$

where n is number of generalized coordinate system, q_i represents the generalized coordinate, \dot{q}_j stands for the generalized velocity, Q_j is the generalized force or generalized torque applied to the j th coordinate.

The total kinetic energy of drive motors in each dynamics model of LEPES is:

$$E_I = \frac{1}{2} (I_{B_1} \dot{q}_{B_1}^2 + I_{B_2} \dot{q}_{B_2}^2 + I_{F_1} \dot{q}_{F_1}^2 + I_{F_2} \dot{q}_{F_2}^2), \quad (25)$$

where $\dot{q}_{B_1}^2 = \dot{x}_{B_1}^2 + \dot{y}_{B_1}^2$, $\dot{q}_{B_2}^2 = \dot{x}_{B_2}^2 + \dot{y}_{B_2}^2$, $\dot{q}_{F_1}^2 = \dot{x}_{F_1}^2 + \dot{y}_{F_1}^2$, $\dot{q}_{F_2}^2 = \dot{x}_{F_2}^2 + \dot{y}_{F_2}^2$; and $I_{B_1}, I_{B_2}, I_{F_1}, I_{F_2}$ is equivalent moment of inertia of each motor respectively in generalized coordinate system.

The total kinetic energy of links in each dynamic model of LEPES can be calculated as follows:

$$E_K = \sum_{i=0}^6 E_{K_i}, \quad (26)$$

where $E_{K_i} = \frac{1}{2} m_i v_i^2$, $v_i^2 = \dot{x}_i^2 + \dot{y}_i^2$, $i = 0, 1, \dots, 6$, m_i is equivalent mass of each links, v_i stands for the velocity of each link in the generalized coordinate.

Thus, the total kinetic energy of each dynamic model of LEPES can be obtained, in accordance with the Eq. (25) and Eq. (26):

$$E_{K_I} = E_K + E_I = \frac{1}{2} \left(\sum_{i=0}^6 m_i (\dot{x}_i^2 + \dot{y}_i^2) + I_{B_1} \dot{q}_{B_1}^2 + I_{B_2} \dot{q}_{B_2}^2 + I_{F_1} \dot{q}_{F_1}^2 + I_{F_2} \dot{q}_{F_2}^2 \right). \quad (27)$$

The total potential energy of each dynamic model of LEPES is:

$$E_P = \sum_{i=0}^6 E_{P_i}, \quad (28)$$

where $E_{P_i} = m_i g y_i$, g is the component of acceleration of gravity along y -axis.

The Lagrangian function for each dynamic model can be expressed as below, based on the Eq. (27) and Eq. (28):

$$L = E_{K_I} - E_P = \frac{1}{2} \left(\sum_{i=0}^6 m_i (\dot{x}_i^2 + \dot{y}_i^2) + I_{B_1} \dot{q}_{B_1}^2 + I_{B_2} \dot{q}_{B_2}^2 + I_{F_1} \dot{q}_{F_1}^2 + I_{F_2} \dot{q}_{F_2}^2 \right) - \sum_{i=0}^6 m_i g y_i. \quad (29)$$

Therefore, according to Eq. (24) and Eq. (29), the Lagrange equation of each dynamic model in the j th generalized coordinate can be obtained:

$$Q_j = \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{\theta}_j} \right) - \frac{\partial L}{\partial \theta_j}. \quad (30)$$

Finally, the entire kinetic equation of each dynamics model can be expressed as:

$$Q = [Q_0 \quad Q_1 \quad Q_2 \quad Q_3 \quad Q_4 \quad Q_5]^T. \tag{31}$$

In accordance with the Eq. (31), in the double-feet support model, Q_0 and Q_5 represented the actuated torque of ankles, Q_1 and Q_4 stand for the actuated torque of knees, Q_2 and Q_3 are the actuated torque of hips. In the double-feet support with one redundancy model, Q_0 and Q_5 represent the actuated torque of ankle that the toes kicking ground and the ankle which the whole foot supporting ground respectively, Q_1 and Q_4 stand for the actuated torque of knee that the toes kicking ground and the knee which the whole foot supporting ground respectively, Q_2 and Q_3 are the actuated torque of hip that the toes kicking ground and the hip which the whole foot supporting ground respectively. In single-foot support model, Q_0 and Q_5 represent as the actuated torque of ankle that the foot swing and the ankle which the foot supporting ground respectively, Q_1 and Q_4 stand for the actuated torque of knee that the foot swing and the knee which the foot supporting ground respectively, Q_2 and Q_3 are the actuated torque of hip that the foot swing and the hip which the foot supporting ground respectively.

4. Simulations verification

In this Section, MATLAB and ADAMS are used to verify the accuracy of D-H equation of kinematics and Lagrange equation of dynamics respectively.

According to the design principles of exoskeleton mentioned in literature [7], this paper assumes the kinematical parameters of LEPES as listed in Table 2.

Theoretically, according to Eq. (7), the homogeneous transformation matrix can be obtained using the parameters in Table 2:

$${}^0M_6 = \begin{bmatrix} 0.87 & -0.50 & 0 & 759.82 \\ 0.50 & 0.87 & 0 & 119.98 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{32}$$

By virtue of MATLAB, the simulation result of the LEPES's kinematics model is consistent with the theoretical result, as illustrated in Fig. 6.

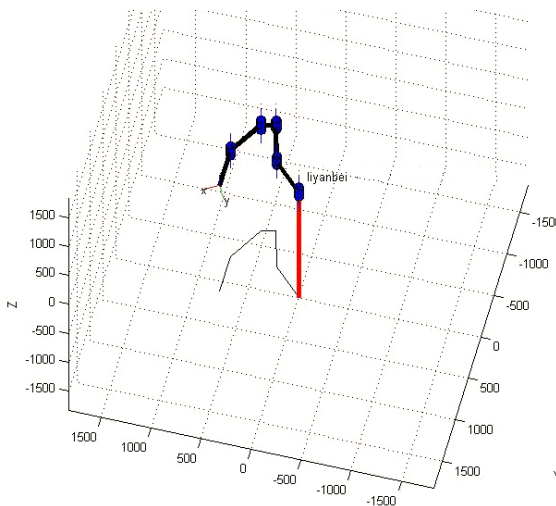

Fig. 6. The simulation result of kinematics model by MATLAB

Table 2. The given kinematical parameters of LEPES

Link	Length	Joint variable	Angle
l_1	420 mm	q_1	$-\frac{\pi}{4}$
l_2	419 mm	q_2	$-\frac{\pi}{6}$
l_3	200 mm	q_3	$\frac{\pi}{2}$
l_4	419mm	q_4	$\frac{\pi}{4}$
l_5	420 mm	q_5	$\frac{\pi}{6}$
		q_6	$-\frac{\pi}{3}$

As for the simulation of the dynamic model of LEPES, in order to get the accurate result of

dynamics simulation, the data of human gait mentioned in literature [8] and ADAMS are used. Fig. 7 shows the virtual prototype of the LEPES's dynamic model built by ADAMS, and the torques of actuated motors can be obtained by the simulation, as shown in Fig. 8.

According to Fig. 8, the motor torque of the hip joint is the largest, while the torque of ankle is the smallest. Thus, there is no need to set motors to drive the ankles; instead, the DOFs of ankles can be regarded as the assistant DOFs when designing the structure.

5. Conclusions

In conclusion, from kinematical views of the lower extremity power-assisted exoskeleton system which is designed by our Robotic Laboratory, this paper described the kinematical characteristics of the lower extremity power-assisted exoskeleton system (LEPES) via Denavit-Hartenberg (D-H) convention, and the homogeneous transformation matrix that could describe the position and posture of the kinematical model of LEPES was obtained. Thus, the precise position and gesture of the end ankle could be obtained according to the kinematical

equation and the θ_i ($i = 1, 2, \dots, 6$) given by the further researches which put forward an improved control strategies. Therefore, this research on kinematics provided a significant theoretical basis for the further study on control strategies and control algorithm of the actuated motors.

In addition, as for the dynamic analysis, Lagrangian dynamics was applied to get the kinetic equations of the three dynamic models of LEPES. And the kinetic equation of each model is obtained. According to the Lagrangian dynamics of LEPES, the theoretical torque of each motor in each model could be calculated, which was helpful to choosing the drive motors of LEPES and optimizing the whole structure. Therefore, this research on dynamics provided an essential theoretical basis for the motor selection and the optimization design of mechanical structure.
