4 **ABSTRACT:** The so-called fourth revolution in the water sector will  
5 encounter the Big data and Artificial Intelligence (AI) revolution. The  
6 current data surplus stemming from all types of devices together with  
7 the relentless increase in computer capacity is revolutionizing almost  
8 all existing sectors, and the water sector will not be an exception.  
9 Combining the power of Big data analytics (including AI) with  
10 existing and future urban water infrastructure represents a significant  
11 untapped opportunity for the operation, maintenance, and rehabil-  
12 itation of urban water infrastructure to achieve economic and  
13 environmental sustainability. However, such progress may catalyze  
14 socio-economic changes and cross sector boundaries (e.g., water  
15 service, health, business) as the appearance of new needs and business  
16 models will influence the job market. Such progress will impact the academic sector as new forms of research based on large amounts  
17 of data will be possible, and new research needs will be requested by the technology industrial sector. Research and development  
18 enabling new technological approaches and more effective management strategies are needed to ensure that the emerging framework  
19 for the water sector will meet future societal needs. The feature further elucidates the complexities and possibilities associated with  
20 such collaborations.

### 1. THE FOURTH-REVOLUTION IN THE WATER SECTOR ENCOUNTERING THE AI REVOLUTION

22 The water sector is undergoing the so-called fourth  
23 revolution,<sup>1</sup> which involves establishing water conservation  
24 strategies and transitioning toward closing water loops.  
25 Meeting our water requirements should not rely only on  
26 imported water, but on our ability to turn our urban  
27 wastewater, stormwater, and other potential hydric sources  
28 into a reliable and sustainable water supply. An example is the  
29 transition of conventional wastewater treatment toward the  
30 conception of water resource recovery facilities (WRRFs)  
31 where wastewater will not only be considered as a resource for  
32 water, energy, heat, and chemicals,<sup>2,3</sup> but also a source of data-  
33 rich information.

34 While the academic and industrial water sectors are pushing  
35 for the consolidation of the fourth revolution, another  
36 revolution concerning big data and artificial intelligence (AI)  
37 has recently emerged in all societal sectors. There are divergent  
38 views about the potential of big data analytics to disrupt the  
39 water sector, but there is little doubt it will change  
40 progressively, and inevitably, the way we think and provide  
41 infrastructure services. An estimate 80% and 50% of the  
42 utilities in developed and developing countries, respectively,  
43 are expected to undergo a digital transition, to some extent, by  
44 2025.<sup>4</sup>

Fast advances in affordable sensors, high-resolution remote  
51 sensing, communication technologies, and social media are  
52 contributing to the proliferation of big data in the water sector  
53 and are likely transforming traditional decision-making  
54 strategies. Big data analytics together with AI (and its  
55 associated machine learning methodologies) are set to bring  
56 new opportunities and challenges into the water sector.<sup>5</sup> The  
57 intertwining of AI with big data science, with new ways to  
58 analyze, organize, and extract information from large volumes  
59 of varying types of information, is bringing new opportunities  
60 for data-driven discovery.<sup>5,6</sup> Decisions once based on  
61 experience and intuition could soon be guided by the analysis  
62 of massive amounts of data. How long this process will take is  
63 unclear, but critical changes in the water sector are looming.

**Applying Big Data beyond Small Problems in the Water (Research) Sector.** Recent literature shows examples  
64 of big data and AI for urban water infrastructure operation and  
65 asset management (see the following section). Such examples

Published: March 10, 2020

63 range from classical theory-based science approaches (e.g.,  
64 using mechanistic models or empirical knowledge) to theory-  
65 free data-driven models (i.e., “pure” big data). Small problems  
66 (i.e., online recommendations) are well-structured cases  
67 characterized by repeated evaluation of predictions even if  
68 the statistical techniques may be complex and the computa-  
69 tional and storage cost may be very large.<sup>7</sup> Such small  
70 problems can be tackled with “pure” big data. However, the  
71 water sector faces complex problems due to its multi-  
72 disciplinary nature and needs strategic solutions toward new  
73 sustainable water infrastructure.<sup>8–10</sup> Hence, water research is  
74 finding useful intermediate approaches between the two  
75 extreme cases of classical theory-based science and pure big  
76 data. The following examples are provided to illustrate the  
77 benefits and implications of big data and AI for (1) urban  
78 water asset management; (2) enhancing the operation of urban  
79 water infrastructure; and (3) recovering crucial information  
80 about the health and lifestyle habits of individual citizens and  
81 communities from data sources coming from the water sector.  
82 Afterward, a discussion is provided concerning the transition  
83 toward new workforce that enables the integration of big data  
84 and AI with the fourth revolution.

85 **1.1. Benefits of Big Data and AI in Urban Water**  
86 **Infrastructure Asset Management.** In most western countries,  
87 the water infrastructure is clearly aging, and (re)investment is  
88 not able to keep up with current needs which will likely worsen  
89 the existing stagnation of the sector.<sup>10,11</sup> Public utilities have  
90 often missed out on charging full-cost tariffs and engaged with  
91 highly discounted rates, leaving themselves confronted with a  
92 backlog of investments,<sup>12</sup> and compromising their current  
93 ability to embark on large-scale infrastructural projects or even  
94 to meet the required maintenance of the drinking water and  
95 wastewater infrastructure. As an example, EPA estimated the  
96 cost of the capital investment that is required to maintain and  
97 upgrade the water systems across the U.S. in 2010 at \$91  
98 billion.<sup>11</sup>

99 Collection systems have a lifespan of approximately 100  
100 years or more, while WRRFs are expected to last at least 50  
101 years.<sup>11,13</sup> AI-powered approaches may provide opportunities  
102 to alleviate the (re)investment needs of water utilities by  
103 extending the service life of existing long-term water  
104 infrastructure assets through a set of strategies to intensify,  
105 maintain, rehabilitate, and replace infrastructure. Numerous  
106 are the examples of advances on leakage detection which can  
107 improve the prediction capabilities in both collection networks  
108 and treatment facilities to reduce inefficiencies and breakdowns  
109 with their associated costly downtimes and repair.<sup>14,15</sup> The  
110 case of the White House Utility District that saved more than  
111 \$20 million by identifying leaks in their infrastructure system  
112 with digital technologies illustrates the potential of these  
113 strategies.<sup>16</sup> In just a few years, unthinkable advances were  
114 made in infrastructural supervision with the support of AI  
115 capabilities, from cost-effective leak detection powered by  
116 satellite imaging<sup>17,18</sup> to the use of magnetic sensors to measure  
117 pipeline thickening to detect weak walls,<sup>19</sup> or even to  
118 pinpointing almost undetectable leaks through vibration-  
119 based signals.<sup>20,21</sup> Similarly, a data driven model developed  
120 by Cameron et al. (2017) enabled the prediction of the  
121 number, location, and type of chokes in collection system  
122 assets.<sup>22</sup> Further improvements extending asset life are being  
123 obtained from the integration of various types of data (i.e.,  
124 structured and unstructured) from sources across utility  
125 departments such as the finance department, work order

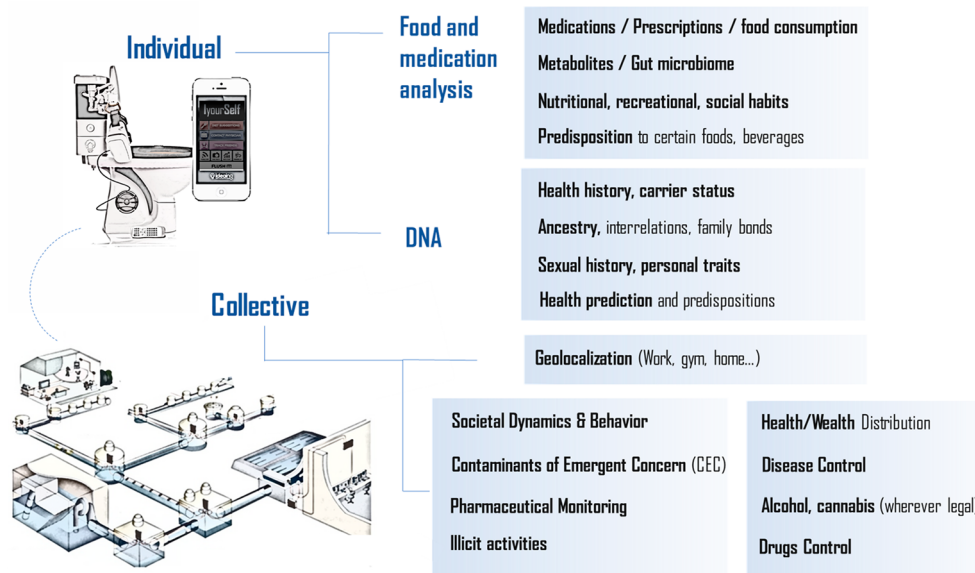

systems, GIS system, and supervisory control and data  
acquisition (SCADA) systems.<sup>23–25</sup> Available cloud services  
support such approaches, for they not only facilitate the  
integration of numerous signals but also incorporate data  
mining capabilities to unveil hidden pieces of information that  
can improve the anticipation of problems through pattern  
recognition.<sup>26,27</sup>

Furthermore, a wide array of applications combining AI  
methodologies with low-cost sensors and affordable commu-  
nication networks will create dynamic, strategic, and financial  
operations for their utilities. Various examples and applications  
of AI-based strategies providing support on early detection and  
prediction are (1) proactive maintenance with real time  
monitoring and event detection;<sup>28–30</sup> (2) smart metering;<sup>31–34</sup>  
or (3) remote sensing products to provide early detection and  
prediction of wastewater conditions.<sup>35–39</sup>

142 **1.2. The Role of Big Data and AI Enhancing the**  
143 **Operation of Urban Water Infrastructure.** Classical theory-  
144 based science approaches (e.g., mechanistic or empirical  
145 models) have been extensively (and successfully) applied in  
146 the water field. The water treatment field has benefited from  
147 model developers and process engineers who have helped  
148 produce mechanistic models encapsulating knowledge to  
149 describe water fluxes and pollutants transformations occurring  
150 in drinking water plants, water distribution networks,  
151 collection systems, WRRFs, and rivers. These mechanistic  
152 models can now fall within the definition of digital twins; the  
153 term refers to virtual replicas of the infrastructure assets  
154 allowing the analysis of data and monitoring of systems to  
155 avoid problems before they even occur, prevent downtime, or  
156 plan for the future.<sup>40–42</sup> Examples of these digital twins are the  
157 well-known simulation platforms for drinking water distribu-  
158 tion networks (e.g., EPANET), for collection systems (e.g.,  
159 SWMM, infoworks), for WRRFs (e.g., Aquasim, Biowin, GPS-  
160 X, Simba#, Sumo, WEST), and, even for groundwater or other  
161 water-related domains (e.g., DHI, 2019). Such digital twins  
162 have been extensively used for process design/upgrade and  
163 optimization. However, the use of these mechanistic models in  
164 day-to-day operations is rather limited, especially for the  
165 infrastructure that relies on biological processes. Furthermore,  
166 to the best of our knowledge, there are not yet applications of  
167 mechanistic models operating in automated manner urban  
168 water infrastructure. The limiting prediction capabilities of  
169 existing mechanistic models under anomalous conditions is  
170 probably the limiting factor. An additional evident limiting  
171 factor is the inability of such digital twin to address processes  
172 yet to be completely modeled (e.g., greenhouse gas emissions  
173 from WRRFs).

Theory-free data-driven models have been applied to the  
enhancement of the operation of WRRFs,<sup>14,44–48</sup> and of  
drinking water treatment plants and distribution networks.<sup>49,50</sup>  
However, the scientific community is reluctant to accept black-  
box models (because they lack mechanistic explanation of the  
underlying processes), even though these models have the  
potential of achieving more accurate performance within a  
broader domain.

The hybridization of mechanistic and pure big data models  
has the potential to transform how the day-to-day operation of  
urban water infrastructure is traditionally done.<sup>6</sup> Whereas AI  
applications to the water sector focus on modeling, their  
optimization, or data mining for knowledge generation, their  
encapsulation into functional decision support systems (DSS)  
is not fully explored. Few academic applications have made it

**Figure 1.** Technological advances in sewer mining and data analytics have the potential to open a new source of data-rich information, both at individual and collective level.

189 into decision making practice (e.g., Corominas et al., 2018).  
 190 We believe that the reason behind this missed opportunity is  
 191 not related to the methods themselves but rather to the  
 192 historical disconnect between the fields of water and computer  
 193 engineering, the limited practical experience of academics, and  
 194 the great complexity inherently associated with these problems.  
 195 Although pure big data models could enhance traditional  
 196 control practice in the water infrastructure, a layer of  
 197 intelligence should be added on top of the traditional control  
 198 algorithms. Such layer can be based on AI self-learning  
 199 capabilities using concepts such as supervised or reinforcement  
 200 learning.<sup>51–55</sup> Such an intelligence layer would be able to  
 201 detect the abnormal behavior of the process or of sensors and  
 202 trigger fallback strategies that deliver maximum acceptable  
 203 performance under certain equipment/process constraints  
 204 (e.g., Schraa et al., 2018).<sup>56</sup>

205 In order to transform data into actionable insights, or  
 206 knowledge, for enhancing the operation of urban water  
 207 infrastructure, it is essential to ensure and verify the quality  
 208 of signals coming from online sensors, as they can produce  
 209 signals of questionable quality due to exposure to harsh  
 210 environments, or due to inadequate or overzealous main-  
 211 tenance (e.g., Cecconi et al., 2019).<sup>57</sup> One essential research  
 212 task is the development of algorithms for automatic data  
 213 quality verification (e.g., from sensors used in control loops).  
 214 In this sense, a plethora of methods have been applied such as  
 215 artificial neural networks, principal component analysis, fuzzy  
 216 logic, clustering, independent component analysis, partial least-  
 217 squares, self-organizing aps, regression, support vector  
 218 machines, and qualitative features detection (*inter alia*,  
 219 Moseithe et al., 2018; Corominas et al., 2018).<sup>58</sup> However,  
 220 limited guidance and no standard exist for the selection of  
 221 methods to tackle a specific sensor failure detection, diagnosis,  
 222 and isolation.

223 Nowadays, the implementation of AI approaches is hindered  
 224 by challenges in data processing (turning data into information  
 225 and into actionable knowledge), data availability (making  
 226 useful information available to stakeholders), data quality, data  
 227 costs (achieving low operation and maintenance costs for

sensors and measurements), and the lack of general standards  
 228 and protocols for data management (Eggimann et al., 2017).  
 229 Therefore, the associated needs for skilled workforce appear  
 230 evident, as discussed in Section 1.4.  
 231

1.3. *The Role of Big Data and AI to Recover Information  
 about the Lifestyle Habits of Citizens from Data Sources  
 Coming from the Water Sector. Will Big Data Make Privacy  
 Obsolete? Or it May Transform It into a Business?*  
 Innovation is quickly and inevitably changing the way we  
 think and provide water services. Processes are being  
 transformed and boundaries across sectors are shifting.<sup>59</sup> In  
 many sectors, technology is disrupting processes and market  
 structures. Solar-powered self-driving vehicles are blurring the  
 boundaries between energy and transport sectors. In the water  
 sector, however, there are unavoidable differences, as water has  
 the potential to become one of society's most important  
 sources of information. Technology will soon have the capacity  
 to extract from water and wastewater-related services (e.g.,  
 through smart metering, sewer mining, etc.) the most intimate  
 information from both individuals and communities about  
 their state of health, genetics, nutrition habits, substance abuse,  
 etc., blurring boundaries between water service, health,  
 nutrition, and business as never before (Figure 1).  
 250

The information available through smart water metering is  
 251 relevant for industries and complements the valuable  
 252 information about citizens that is already available to  
 253 information technology (IT) companies;<sup>60–62</sup> however, waste-  
 254 water presents an untapped source of data-rich content about  
 255 the citizenry. Cities and their communities/neighborhoods can  
 256 make use of their collection system to understand lifestyle  
 257 habits and overall health status through measuring human  
 258 biomarkers, through information mining.<sup>63</sup> Human biomarkers  
 259 can be either metabolites of exogenous substances (produced  
 260 through metabolic processes after consumption) or endoge-  
 261 nous compounds (produced naturally in the body), and they  
 262 are continuously flowing through our collection system waiting  
 263 to be harvested and measured. After toilet flushing, biomarkers  
 264 end up in the collection system and, together with many other  
 265 compounds, are diluted with water and transported to WRRFs 266

267 where they are totally or partially removed before being  
268 discharged to receiving water bodies. The potential knowledge  
269 that could be distilled from analyzing our urban effluents offers  
270 a limitless array of possibilities ranging from monitoring  
271 population dynamics (i.e., medication usage, disease control,  
272 public health issues), elucidating dietary habits of entire  
273 societies (e.g., consumption of brand-specific food, drugs and  
274 alcohol use, prescription medication, etc.) and even providing  
275 advice on individual needs (detection of health risk factors,  
276 customized dietary advice, aging prevention counseling). The  
277 technology exists, and it is only a question of time before  
278 economy of scales and market forces will make reasonably  
279 feasible screening and processing data from individuals and  
280 communities connected to the collection system, unveiling our  
281 predisposition from developing cancer to which sport we  
282 should play.

283 Until now, the largest progress on wastewater information  
284 mining has been made on the estimation of illicit drug  
285 consumption.<sup>64–67</sup> Yet, the full potential has not been explored  
286 as there are still limitations in the analytical procedures in  
287 terms of accuracy and precision related to the development of  
288 capabilities to measure the concentration of these biomarkers  
289 in real-time.<sup>68</sup> The research in this field requires big data  
290 analytics, as the processing of information from one sample  
291 may need to be analyzed in tandem with other information  
292 such as gut microbiome diversity, sales in pharmacies,  
293 supermarkets, wastewater characteristics, etc. for reliable  
294 outputs. The penetration of the privately owned technology  
295 and service companies in the resource recovery sector would  
296 give them potential access to our genetic predispositions, diet,  
297 daily dynamics, ancestry, metabolism, health monitoring,  
298 alcohol, medications, illicit drug use, etc. The knowledge that  
299 can be potentially extracted either directly or indirectly (by  
300 applying correlations between other easily measured param-  
301 eters) appears limitless and may unlock unforeseen scenarios.

302 Beside the technological potential of maximizing resource  
303 recovery, data mining and processing from the water sector has  
304 the potential of improving living conditions. Not only could  
305 our lives change due to the prospect of having the option to be  
306 continuously informed and guided about health (e.g., disease  
307 predisposition, recovering follow-ups, tailored health programs,  
308 etc.) and lifestyle (e.g., dietary recommendations, personal-  
309 suggested activities, sport-recommendation with its corre-  
310 sponding associated products, etc.), but also the job market  
311 will likely experience further deep transformations.<sup>69</sup> However,  
312 we should not overlook potential concerns with respect to  
313 privacy and ethics, which arise from the continuous extraction  
314 of sensitive (and valuable) data flowing from the water system.

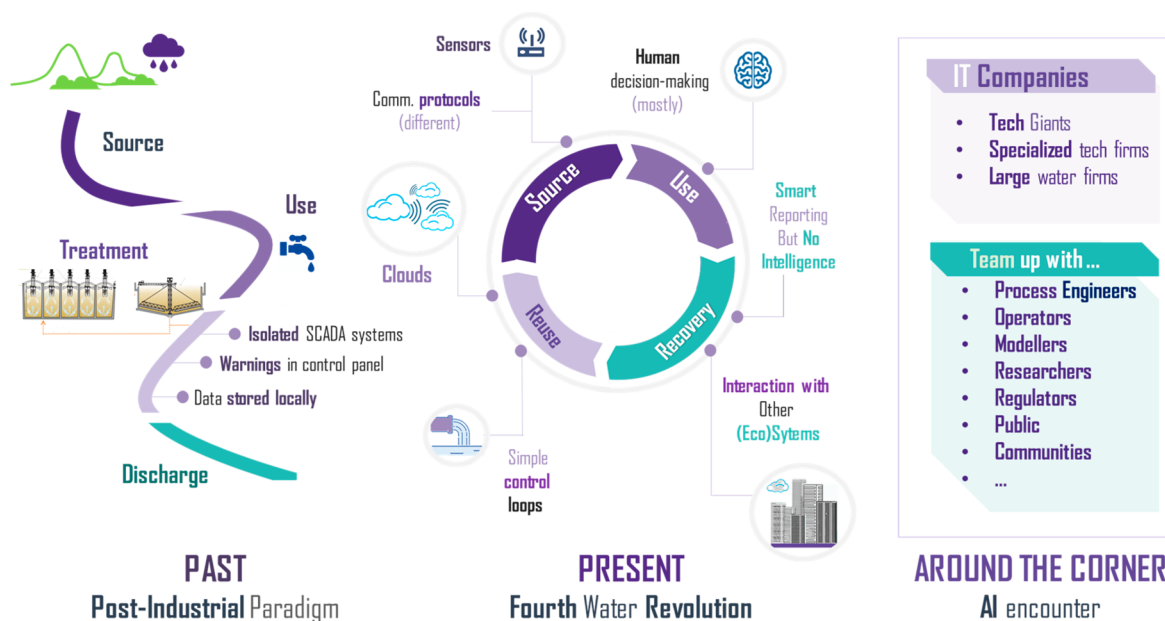

315 **1.4. The Role of Big Data and AI on Resource Recovery**  
316 **and Source-Separation.** Although the prospect of retrieving  
317 information from urban wastewater streams is currently  
318 attracting the most attention, resource recovery from the  
319 water and wastewater cycle should not be overlooked.  
320 Developments in AI and new digital platforms could collate  
321 not only distributed data on resources (e.g., household-level  
322 water and energy data from smart sensors), but also data on  
323 produced resources at WRRFs (e.g., phosphate, cellulose  
324 fibers, biogas, recycled water, bioplastics, biopolymers, etc.). In  
325 a time when the production of these valuable resources is  
326 matching current market demand and prices,<sup>2</sup> AI-powered  
327 strategies could facilitate the market penetration of such  
328 products with precise monitoring of the product quality (e.g.,  
329 image processing), optimal demand-supply balancing (e.g.,

dynamic pricing), and likely providing new proxy approaches  
330 to reduce current technical limitations as real-time analysis. 331

332 Similarly, the consolidation of concepts until now scarcely  
333 implemented but deemed as potential solutions to some of the  
334 most pressing challenges in the nearer future, as decentral-  
335 ization and source separation,<sup>2,70,71</sup> could also benefit from  
336 developments in digitalization and AI. Both the construction of  
337 smaller and simpler decentralized systems (enabling the  
338 minimization of costs and fewer imports), or source-separation  
339 approaches (avoiding energy-demanding, increased recovery  
340 rates, and reduced transport), should benefit from new digital  
341 strategies. Extracting increased value from the different streams  
342 also means increasingly complicated processing. Facilitating  
343 the interconnectivity and data sharing between different  
344 processes, technologies and decentralized sites would require  
345 higher intelligence, monitoring, and autonomous supervision.  
346 Powerful platforms together with secure data transferring (i.e.,  
347 blockchain) could further value and improve trading of  
348 recovered resources, incentivizing individuals, companies and  
349 governments to unlock the financial value from materials  
350 traditionally regarded as economically invaluable.<sup>72</sup> It must be  
351 noted that information extraction when using source  
352 separation schemes would imply differentiated sampling and  
353 data-retrieving approaches than sewer mining. The different  
354 variants that may result from a successful source separation  
355 approach (i.e., urine separation, gray water, black water, etc.)  
356 will necessarily need tailored solutions to obtain the same data  
357 or information resolution.”

358 **1.5. The New Workforce and Water Research. 1.5.1. The**  
359 **Automation Paradox.** The integration of AI within the fourth  
360 water revolution also has its counterpart. Consulting  
361 companies Price Waterhouse Coopers and Deloitte together  
362 with Oxford University projected that the water and waste  
363 management sector would suffer the most changes among a list  
364 of 50 sectors due to automation and AI irruption, predicting  
365 that close to 60% of the current related jobs are under threat  
366 within the next 15 years.<sup>73,74</sup> The most vulnerable jobs due to  
367 progressive digitalization are those related to the automation of  
368 low-level tasks, according to current forecasts. Many simple-  
369 repetitive tasks needed in the management of the urban water  
370 cycle elements could be potentially automated at relatively  
371 low-cost. For example, the implementation of a level meter in  
372 chemical storage tanks that could automatically trigger the  
373 purchasing procedure. However, some authors reject similar  
374 gloomy predictions suggesting that AI will likely not displace  
375 many of the workers, as automating certain tasks can free  
376 workers from repetitive tasks enabling them to focus on more  
377 highly skilled aspects (Abbatiello et al. 2017). Additionally, the  
378 requirement of licensed operators to take actions in treatment  
379 facilities will and should not be forfeited for efficiency, due to  
380 their associated authority and supervisory responsibility.

381 **1.5.2. Water Workforce.** Earlier sections discussed how AI  
382 has become a dynamic topic with many innovative applications  
383 promising to disrupt the field; however the full range of its  
384 impact on the water workforce and researchers remains  
385 nebulous. A few factors ranging from lack of incentives, risk  
386 of adoption, and preference for proven technologies could  
387 contribute to slowing the adoption of AI and big data  
388 analytics.<sup>59</sup> Nonetheless, few strategies could be crucial to  
389 scaling the adoption of digital technologies. While the creation  
390 of hubs working closely with utilities have already shown  
391 promising cases,<sup>75–78</sup> perhaps the most important approach to  
392 a successful digital implementation will require a new water

**Figure 2.** Conceptual evolution of the water management paradigm over the last decades: from the postindustrial third water revolution to the still settling fourth revolution, and to the upcoming AI encounter.

393 sector workforce adopting the required skills to keep up with  
 394 the pace of digital evolution.<sup>79</sup> A few reviews offer further  
 395 insights into the workplace challenges of adopting water data  
 396 technologies (e.g., Cespedes and Peleg, 2017; Daigger et al.,  
 397 2019)

398 **1.5.3. Role of IT Companies.** AI has the potential to create  
 399 trillions of dollars of value across the economy.<sup>81</sup> It is  
 400 estimated that the potential value unlocked by AI in the water  
 401 resource recovery sector is up to \$22.8B in 2017 and is  
 402 projected to grow by 7.2% annually from 2017 to 2021.<sup>82,83</sup>  
 403 The water sector is slowly becoming attractive for technology  
 404 giants who are unhurriedly testing the waters of a revenue-  
 405 promising field by overlaying data management and AI  
 406 capabilities on existing water and wastewater treatment  
 407 businesses (e.g., IBM Bluemix, GE Predix, etc.; Krause et al.,  
 408 2018). These platforms provide capabilities in remote asset  
 409 monitoring, energy analytics, and water security. The  
 410 integration of all types of data it is supposed to facilitate  
 411 critical decision-making relative to assets and optimize security  
 412 and reliability.

413 Digitalization is sought by multiple segments: from  
 414 technology giants with rather limited process knowledge to  
 415 specialized smaller water technology companies with the know-  
 416 how but rather limited analytical platforms or infrastructure.  
 417 Large water technology companies (technology developers and  
 418 technology/service providers) are also investing in digital-  
 419 ization and are generating the demand for it. In either case, big  
 420 or small technology companies will have to include water  
 421 processes knowledge or water academics will have to adapt to  
 422 this reality by embracing the new tools of big data analytics.  
 423 The differing interests from the water research community and  
 424 the technology giants might be a limitation to pursue the  
 425 effective integration of AI tools in the sector. However, a clear  
 426 opportunity arises for those utilities, clean-technology  
 427 companies, academic institutions, or partnerships of them  
 428 already operating in the water and resource recovery industry.  
 429 Independent actors or partnership can enter this still untapped

market and fill an important role in a meaningful way to the  
 water industry. **Figure 2.**

430 £  
 431 £  
 432 **1.5.4. Water Research Workforce.** New skills will not only  
 433 be required in water infrastructure but will also be fundamental  
 434 to prepare the next generation of water researchers to be more  
 435 proficient in data science and to design semantically rich and  
 436 reproducible data products.<sup>6</sup> Nevertheless, reality is showing  
 437 that researchers are not fully prepared to make use of the  
 438 technological developments brought by digitalization to the  
 439 fullest extent.<sup>84</sup> Debate exists on whether researcher skills for  
 440 using fully the digital potential will be different from the long-  
 441 recognized skills relevant in academia. Big data has the  
 442 potential to change fundamentally the way that water  
 443 researchers are conceiving, conducting, and analyzing experi-  
 444 ments. Already the established rules in the scientific  
 445 community supporting the indexing system, which prioritizes  
 446 results and not data, are being called into question. As data  
 447 continues its trajectory to become the new “currency” of  
 448 research outputs for researchers,<sup>84</sup> data sharing in full  
 449 transparency and repeatability become a new norm and  
 450 current attitudes and behavior in the scientific community will  
 451 need to adapt. While critical concerns from the implications of  
 452 real open access, privacy, and legal aspects are arising from this  
 453 trend of data sharing, the current trend is that communication  
 454 through data is already being valued more than actual  
 455 engineering or research skills.<sup>85</sup> Consequently, the researchers’  
 456 skillsets will have to adapt toward not only strong data analysis,  
 457 but also in the understanding of a new environmental and legal  
 458 framework enabling the next level data communication.

459 To the greatest extent, water researchers today are not  
 460 trained on digital technologies or implementing hybrid  
 461 solutions between old theory-based modeling and the new  
 462 array of emerging big-data elements. A new set of needs are  
 463 necessary to scale the adoption of digital technologies for  
 464 effective big data exploitation: (1) integration of knowledge  
 465 from different types of sources; (2) successful hybridization  
 466 between big data management platforms to address bottle-  
 467 necks on using either pure big data-elements or solely theory-

468 based modeling; and (3) ensuring data quality from sensors. A  
 469 sound transition toward AI-driven urban water systems will  
 470 indeed require that new generation of researchers/practitioners  
 471 be trained in engineering, statistics, and computer science  
 472 through the creation of multidisciplinary training programs.

473 Such integration of knowledge within the water sector is  
 474 now being promoted by the International Water Association  
 475 through its Digital Water Programme<sup>86</sup> and Water Environ-  
 476 ment Federation through intelligent water systems,<sup>87</sup> by  
 477 including forums for discussions (e.g., Knowledge Develop-  
 478 ment Forum, International Society of Automation's) collecting  
 479 and exchanging of methodologies, and practical experiences.  
 480 Specialist groups (e.g., Instrumentation, control and automa-  
 481 tion -ICA- and Digital Water Programme from IWA) have  
 482 embraced significant progress in developing low-cost water-  
 483 related sensors, models, and control algorithms with a very  
 484 effective combination of process knowledge and ICA tools.  
 485 Other groups (e.g., the WEFTEC Research and Utility  
 486 Management Symposia) have focused dedicated tracks to  
 487 data analysis/management and workforce training.

488 As computer capacity continues escalating and data  
 489 management techniques (data curation, data mining, etc.)  
 490 are improving, which in turn enhances knowledge extrac-  
 491 tion,<sup>14,47,88</sup> collaborations between teams of engineers, data  
 492 and computer scientists, and researchers will be imperative to  
 493 create the conditions to successfully embrace the digitalization  
 494 of the water sector and leverage process knowledge, data  
 495 analytics, and technology to bring out the full potential of data.  
 496 Refs 43 and 80.
