## Introduction

The commercial property sector is an important economic engine that suffers loss and disruption as a result of flooding and may be at increased risk in the future (Committee on Climate Change, 2015). Commercial property transactions are an important part of a national investment portfolio (Savills, 2016) and any risk to these asset values can threaten local or even national economic stability. Furthermore, businesses operating within commercial property are a vital part of local economies and are integral to community recovery. Therefore understanding the impact of flooding on commercial property value and the potential to mitigate this impact through risk transfer and loss reduction measures for existing property can support sustainable property markets in areas at risk, as well as the communities they support (Tobin, 1979).

However property investment, and in particular non-domestic property investment form part of global investment markets and investment funds that may be at threat from flood risk (London Climate Change Partnership, 2009), there are also businesses operating trans-nationally with real estate portfolios to match. Investment managers' performance would be enhanced if understanding of risk pricing was developed on a consistent basis internationally.

Research on the value of property at risk of flooding or having been flooded has generally focussed on the residential property market. The majority of empirical studies, spread internationally, are transactional analyses of observed market price for example (Montz, 1993, Eves, 2004, Sirmans *et al.*, 2005, Bin *et al.*, 2008, Lamond *et al.*, 2010, Pryce *et al.*, 2011, Beltrán Hernández, 2016, Hirsch and Hahn, 2017). Studies have also used expert consultation to explore the process, rationale and causes of discounted valuation (Eves, 2004). Findings from these studies show large variation in the scale of impact observed on market price. Differences in value estimates for different national markets relate to information and perception of risk fostered through different regulatory and insurance

1  
2  
3 contexts (Yeo, 2002, Lamond *et al.*, 2005). However there are also temporal variations in  
4  
5 market price within national and sub-national markets that reflect the point in time value  
6  
7 including economic conditions and saliency of risk (Eves, 2002).  
8  
9

10 Based on rational choice theory, studies in the USA have explored price differentials  
11  
12 in relation to the extra cost of insuring against flood damage and loss (Skantz and Strickland,  
13  
14 1987, Bin *et al.*, 2006). Theory also predicts impacts on market value proportionate to  
15  
16 expected cost of damage repair where insurance is not available or not taken up (Tobin and  
17  
18 Newton, 1986). Imperfect information, denial and heightened risk perception are expected to  
19  
20 hamper market behaviour (Pryce *et al.*, 2011) whereby value is based on perceived rather  
21  
22 than actual risk or supported artificially through subsidised insurance. New information such  
23  
24 as a flood event can therefore cause large and undesirable temporary adjustments in value  
25  
26 that have the potential to become embedded into blight (Pryce *et al.*, 2011).  
27  
28  
29

30  
31 Notwithstanding this, there is far less evidence in the commercial property market. It  
32  
33 is not appropriate to assume that findings can be extended directly from the residential sector,  
34  
35 although the same concepts are relevant to explore. Commercial property transactions are  
36  
37 more likely to be for investment purposes and the proportion of non-domestic buildings that  
38  
39 are owner occupied is much smaller (Property Industry Alliance, 2017). Thereby the purchase  
40  
41 decision may often be arms-length, influenced by different factors. As pointed out by the  
42  
43 Investment Property Forum (2015) valuation points and rental transfers may be more frequent  
44  
45 whilst sales transactions are less frequent and transparent. Studies of the value of commercial  
46  
47 properties at risk in the UK, in the absence of high quality transactional data, have canvassed  
48  
49 expert views and gauged market perception from commercial property owners and occupiers.  
50  
51 (Kenney *et al.*, 2006, Bhattacharya *et al.*, 2013). Kenney *et al.* (2006) noted the importance of  
52  
53 insurance and complexity with respect to physical aspects of potential damage given the  
54  
55 heterogeneity of non-domestic construction. Bhattacharya-Mis and Lamond (2016)  
56  
57  
58  
59  
60

1  
2  
3 demonstrated that use class (such as retail vs industrial property), is a key factor in the  
4 vulnerability of property utility and value. They both point to a vulnerability in the UK  
5 market that is not yet realised in market price but has the potential to cause serious impact in  
6 the future if mitigation is not undertaken (Pottinger and Tanton, 2011). Recent work in the  
7 USA on hurricane risk by Eichholtz *et al* (2018) suggests a discount due to floodplain  
8 location on property price in the aftermath of Sandy around 11% and a study in St. Louis  
9 Missouri found similar effects, albeit not statistically significant, due to absence or presence  
10 of flood protection levees (Fell and Kousky, 2015). An Australian study also including some  
11 commercial property (Rajapaksa *et al.*, 2016) found flood events were more important than  
12 the release of flood risk maps in changing property value. Authors also highlight the duty of  
13 the valuation professional to consider flood risk, thereby avoiding claims of negligence  
14 (Craddock, 2016).

15  
16 Insurance is seen as important since it provides, amongst other things, reliable  
17 compensation and as such supports recovery and reconstruction. Available research also  
18 suggests that insurance and regulation regimes influence the uptake of risk mitigation  
19 measures (Kreibich *et al.*, 2007) and that the regimes vary across different international  
20 markets (Lamond and Penning-Rowell, 2014). In contrast, government compensation  
21 independent of prior actions is assumed to discourage individual precaution and preparedness  
22 (Keskitalo *et al.*, 2014).

23  
24 Therefore the dual aims of the research were to develop an understanding of how  
25 different international insurance and regulatory regimes promote effective flood risk  
26 mitigation for commercial property; and to explore the consistency of international  
27 approaches to the valuation of commercial property at risk from flooding.

## 28 **Research Methods**

29 An illustrative case study design was used to develop a cross country comparison whereby

1  
2  
3 cases are selected to reveal a broad range of experiences rather than be representative of an  
4 average example (Thomas, 2009). This approach is useful in order to illustrate different  
5  
6 approaches, explore best practice and reveal whether outcomes are dependent on the specifics  
7  
8 of the cases. Five countries (Australia, China, Germany, the USA and the UK) were chosen  
9  
10 to represent different insurance and regulatory regimes as understood from previous studies  
11  
12 of insurance systems (Lamond and Penning-Rowse, 2014) and regulation (Defra, 2015).  
13  
14 The research team included local researchers in each country with expertise in flood risk  
15  
16 management and building pathology, and a common approach was adopted across the case  
17  
18 studies to allow for cross comparison and synthesis of findings.  
19  
20  
21  
22  
23

24 A qualitative approach was chosen to illuminate the complexity of the interactions  
25  
26 between practice and governance of this rapidly evolving issue (Robson, 1993). The methods  
27  
28 employed were: a systematic scoping review of literature and grey literature (Collins *et al.*,  
29  
30 2015) to understand the prevailing regimes and opinions at a national level; and interviews  
31  
32 with Built Environment professionals operating in the case study countries to understand their  
33  
34 experiences and perspectives as practitioners with differing opportunities and constraints.  
35  
36  
37

38 The quick scoping review used a systematic search of databases of academic literature  
39  
40 and industry sources, as well as generic search websites. A PICO search query (Collins *et al.*,  
41  
42 2015) was developed on the ISI web of science using terms related to commercial property,  
43  
44 flooding, insurance and valuation that was used to search international databases with country  
45  
46 delimiters. Websites of specialist organisations and local language journals and databases  
47  
48 were also scoped by the country specialists.  
49  
50

51 A semi-structured interview approach allowed common themes to be explored across  
52  
53 case studies, with the necessary flexibility (given different roles and responsibilities of  
54  
55 interviewees) within, and across, case studies. A common set of interview questions was  
56  
57 developed to explore themes identified through the literature review. Two of these themes  
58  
59  
60

1  
2  
3 focussed on the role of flood insurance in the mitigation of flooding and the impact of  
4  
5 flooding on commercial property value.  
6

7  
8 Experts with knowledge and experience of advising on flood risk were targeted in  
9  
10 order to gain the most informed view from a small sample size (Silverman, 2013).

11  
12 Interviewees were therefore purposively selected through a combination of recruitment  
13  
14 methods including social media, known experts, emails from the RICS (a global professional  
15  
16 body for surveyors) to their commercial members and snowball techniques. Such a strategy  
17  
18 was necessary given the expected diversity of roles and professionals involved and the rarity  
19  
20 of individuals with specific flood expertise. A target sample of fifteen (15) semi-structured  
21  
22 interviews in each case study was considered to be appropriate in advance as the point of  
23  
24 theoretical saturation (Strauss, 1998; Gubrium, 2001). As interviews proceeded, the number  
25  
26 of interviewees per country was adjusted as the local researchers judged understanding of the  
27  
28 critical context had been achieved. Data were obtained from interviews with 72 Built  
29  
30 Environment professionals from the five countries. The roles and division of the experts is  
31  
32 shown in table 1.  
33  
34  
35  
36

37  
38 INSERT TABLE 1 here  
39

40  
41 The interviews were transcribed, translated as necessary and coded in suitable  
42  
43 qualitative analysis software (NVIVO and MAXQDA based on the availability at partner  
44  
45 institutions) under a common set of initial and emerging themes. For this process a thematic  
46  
47 content approach to analysis was employed (Braun and Clark, 2006), with each country  
48  
49 expert creating an initial coding of interviewees statements and views under the initial  
50  
51 themes. This was followed by team discussions of preliminary findings and proximal themes  
52  
53 through which emergent themes and subthemes emerged. A second round of coding  
54  
55 followed in which emergent themes and sub- themes were also coded in the data. This  
56  
57  
58  
59  
60

1  
2  
3 allowed the data to be drawn together on a cross national basis under the themes and sub-  
4  
5 themes.  
6

## 7 **Results**

8  
9  
10 The results of the literature review and interviews are combined below to provide a summary  
11  
12 of the insurance regime in each country. This is followed by a thematic evaluation of the  
13  
14 interview findings in relation to risk mitigation, through insurance and property valuation.  
15  
16

### 17 *Insurance and risk management regimes*

#### 18 *Australia*

19  
20  
21 Australian insurance policy-making originated from the policies of UK companies, prior to  
22  
23 the 1968 ‘Gentlemen’s Agreement’ (Huber, 2004). Within a typical policy, ‘flood’ events  
24  
25 were covered, even though the term itself was not defined (Australian Government, 2016). In  
26  
27 1984 the Insurance Council of Australia (ICA) provided a definition of flood<sup>1</sup> that was not  
28  
29 covered by default enabling partial, or fuller, add on ‘flood’ insurance. However the  
30  
31 definition is not clear as multiple interpretations have been applied over the three subsequent  
32  
33 decades.  
34  
35  
36  
37  
38  
39

40 Following extensive flooding in Queensland in 2011, the Federal Government  
41  
42 considered adopting a system of mandatory flood insurance. A National Disaster Insurance  
43  
44 Review (National Disaster Insurance Review Panel, 2011) was undertaken; however, the  
45  
46 government decided not to legislate, with the result that the definition of flood is still  
47  
48 questioned and debated, and the lack of understanding of the difference between a flood and  
49  
50 storm event remains (Australian Government, 2016).  
51  
52  
53  
54  
55

---

56  
57 <sup>1</sup> Described as ‘the inundation of normally dry land by water escaping from the normal confines of  
58  
59 any natural watercourse or lake whether or not altered or modified, or any reservoir, canal or dam’.  
60

1  
2  
3 Participants noted that insurance terms of coverage vary from state to state, with each  
4 having different risk profiles. Insurers in more flood prone areas request that mitigation  
5 measures are adopted, or they impose penalties when mitigation measures are not adopted.  
6  
7 An interviewee commented: *'Brisbane insurers are likely to be red hot on this, whereas in*  
8 *Sydney they wouldn't be because they've not had a lot of flooding here'*.  
9  
10  
11  
12  
13  
14

### 15 16 *China*

17  
18 National government in China states that it encourages companies and citizens to participate  
19 in natural insurance programs in general according to the 2007 *'Emergency Response Law of*  
20 *the PRC'* Ministry of Housing and Urban-Rural Development, 2016). However, as noted by  
21 Shi and Liu (2013) there is no state provision for flood insurance and private companies  
22 therefore dominate the market.  
23  
24  
25  
26  
27  
28

29 Although commercial property owners, landlords or property management companies  
30 are required to purchase property insurance (Li *et al.*, 2015) that covers a limited set of water  
31 damage problems such as rainwater leakage, blocked drainage, escape of water from pipes  
32 and surface water flooding. Fluvial and coastal flooding are not included, need to be  
33 purchased separately and are not mandatory.  
34  
35  
36  
37  
38  
39

40  
41 Gaschen *et al.* (1998) stated that around 80% of property flood insurance schemes are  
42 purchased by large and medium sized commercial enterprises. According to interviews in the  
43 Greater China region, having property insurance is a common practice among land and  
44 property owners. However, they confirmed the limitations of coverage:  
45  
46  
47  
48  
49

50  
51 *...as far as I know most of commercial properties are required to purchase the property*  
52 *insurance and it is combined with flood disaster, fire and other hazards ..... So, I*  
53 *understand the property insurance that my clients purchase normally can cover the cost*  
54 *from surface water flooding includes fixing the lifts or escalators or the flood from pipe*  
55 *leakages and seepages, etc.*  
56  
57  
58  
59  
60

1  
2  
3 Insurance coverage for fluvial, coastal or combined flooding is available from private  
4  
5 insurers but is not compulsory. Commentators have noted that the availability of, and demand  
6  
7 for, both bundled property insurance and extra flood coverage may be enhanced if urban  
8  
9 provincial and local governments support the private insurers with the required risk  
10  
11 information and financial support (Wang *et al.*, 2012, Li *et al.*, 2015).  
12  
13  
14

### 15 16 *Germany*

17  
18 Severe floods in the Rhine catchment in 1993 and 1995 initiated a change towards more  
19  
20 integrated flood risk management in Germany (Bubeck *et al.*, 2017). This was strengthened  
21  
22 following the 2002 event (Kreibich *et al.*, 2011) through the 5-point action programme for  
23  
24 improvements in flood risk management, which led to amendments of the Federal Water Act.  
25  
26 Private precautionary measures are expected from property owners in a floodplain in  
27  
28 accordance with their resources and capabilities (Wasserhaushaltsgesetz (Federal Water Act),  
29  
30 2009).  
31  
32  
33

34  
35 Flood insurance is provided as commercial property insurance and ‘all-risk’ policies,  
36  
37 covering direct damage to assets as well as losses due to business interruption (Jakli, 2003).  
38  
39 Flood insurance penetration in Germany has increased strongly in recent years, but is still low  
40  
41 in comparison with other countries such as the UK (Surminski and Thieken, 2017). There are  
42  
43 large regional differences due to historical compulsory flood insurance in the former German  
44  
45 Democratic Republic and in the federal state of Baden-Wuerttemberg (Schwarze and  
46  
47 Wagner, 2004).  
48  
49  
50

51  
52 Decisions about availability of insurance for small companies (insured value < 2.5  
53  
54 million Euros) depend on the ZÜRS flood zoning system German Insurance Association  
55  
56 (GDV) (GDV, 2016). Premiums and deductibles increase from zone 1 to zone 4, with  
57  
58 properties in flood zone 4 (with floods expected more frequently than 1 in 10 years)  
59  
60

1  
2  
3 considered uninsurable (Schwarze and Wagner, 2004). An expert explained that the GDV has  
4 developed several non-binding adaptable insurance templates for small businesses. However,  
5 interviewees recognised that insurance terms are negotiated on a case by case basis with  
6 industrial and large commercial businesses.  
7  
8  
9  
10  
11

12 In Germany, triggered by the 2002 flood and again by the 2013 flood, political  
13 debates took place about a compulsory flood insurance scheme. However, both initiatives  
14 failed, mainly due to governmental refusal to provide a guarantee for remaining risks  
15 (Schwarze and Wagner, 2004, Surminski and Thieken, 2017). The GDV together with  
16 engineers and Build Environment professionals developed the building certificate “flood  
17 passport (in German: Hochwasserpass)”, launched in 2014 (Thieken *et al.*, 2016). The impact  
18 in the commercial sector is unknown but there is no evidence of a positive effect on the  
19 implementation of precautionary measures for households (Osberghaus and Philippi, 2016).  
20  
21

### 31 UK

32 Commercial property insurance is provided by private companies in the UK and is not  
33 compulsory. Standard policies usually include coverage for flooding of all types, and  
34 ‘business interruption’ insurance can also be purchased to cover flood disruption. Evidence  
35 on the uptake of insurance among business properties from UK Department for Environment,  
36 Food and Rural Affairs (Defra) surveys (Dickman *et al.*, 2015) and the Federation of Small  
37 Businesses (2015) suggests high level of penetration (95%) among small businesses with few  
38 problems of availability. Recent developments, that reduce the commitment of insurers to  
39 universal availability of coverage and the introduction of the Flood Re re-insurance pool  
40 (April 2016) that specifically excludes commercial property, may lead to large increases in  
41 premiums and excesses for small to medium businesses at risk. This may be an important  
42 consideration given that the availability of insurance is a material factor in the valuation of  
43 commercial assets (Kenney *et al.*, 2005).  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3           Bhattacharya-Mis and Lamond (2014) supports these findings, larger companies in  
4 their study were more likely to self-insure and they note that even small businesses may  
5 avoid claiming against their policy to avoid increases in premium. Large commercial  
6 concerns have long been excluded from guaranteed coverage (Huber, 2004).  
7  
8  
9

10  
11  
12           Interviewees had limited knowledge about the details of insurance conditions. As one  
13 expert explained:  
14

15  
16           *There is a bit of a gulf really between the technical engineering and property side of the*  
17 *flood problem and the insurance industry. The insurance industry, typically, has been*  
18 *quite black box with regard to flood risk ...*  
19  
20  
21

22  
23 Another interviewee noted:  
24

25  
26           *I suppose most commercial people go through a broker, to get their insurance, rather*  
27 *than just going online and getting insurance.*  
28  
29

30 However, they were aware that some companies that had been flooded were having problems  
31 obtaining insurance and that this was a serious issue to them.  
32  
33

34  
35  
36 *USA*  
37

38  
39 Under provisions of the US National Flood Insurance Program (NFIP), both commercial and  
40 residential properties located in the administratively-defined 100-year floodplain are required  
41 to carry flood insurance, with the cost of that insurance dependent on the elevation of the  
42 structures relative to the base flood elevation (BFE) and any mitigation that has been  
43 implemented (Hartwig and Wilkinson, 2005; Federal Emergency Management Agency,  
44 2017). For commercial properties, rates are capped at \$500,000 for both building and  
45 personal property (Federal Emergency Management Agency, 2013). While some of those  
46 interviewed agreed that the program encourages mitigation, the extent to which this  
47 requirement influences mitigation varies depending upon a number of factors including the  
48 age of the building, the size of the operation, and ownership characteristics. With respect to  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 age, it may be the case that the costs of mitigating older buildings and buildings with  
4  
5 basements are so high that the offset in premium costs is not seen to make mitigation a good  
6  
7 investment. At the same time, new structures must incorporate flood-proofing into their plans  
8  
9 in order to obtain a building permit, typically through elevation above BFE.  
10  
11

12           Size of the business affects the willingness to undertake mitigation in several ways.  
13  
14 For larger operations, the NFIP cap on flood insurance is often insufficient so these  
15  
16 businesses may be required as a loan condition to carry both an NFIP policy and a private  
17  
18 commercial policy. The extent to which this encourages mitigation is variable. As one  
19  
20 interviewee put it:  
21  
22

23  
24           *my impression is that there is nothing other than a determination to say if you do or do*  
25  
26 *not [need to] buy flood insurance. ... It's not really an appraiser/client relationship*  
27  
28 *where they are giving advice, it's more of a "here is what you need for the loan" file.*  
29

30 Other large operations that are not subject to loan requirements will self-insure, so it is  
31  
32 difficult to obtain information on the extent to which mitigation is used to reduce risk.  
33  
34 Smaller businesses face different issues. As one professional noted, '*some businesses only*  
35  
36 *have the money to keep the doors open and others have the resources to actually look into*  
37  
38 *making their property safer.*' In many cases, small businesses are renters. Once an  
39  
40 appropriate location is found, they typically do not think about flood risk and are not required  
41  
42 to carry flood insurance. The owner of the building may have insurance but that does not  
43  
44 cover the contents of the businesses, only the building.  
45  
46  
47  
48  
49

### 50 ***Take up and motivation for risk mitigation***

51

52  
53 There was largely a consensus among the interviewees across countries that the insurance  
54  
55 industry could have a major influence on the motivation of companies to take active steps to  
56  
57 mitigate against flood risk. However, many perceived that this was not currently the situation  
58  
59 with regard to all commercial properties in their markets and that insurers could do more.  
60

1  
2  
3 This was the case despite differences described above in the regimes under which property  
4 insurance treats flood risk. Reasons offered to explain the perceived failure included two that  
5 were repeated across all five case studies: low take up of insurance policies and lack of a  
6 premium incentive to spend resources on mitigation.  
7  
8  
9  
10  
11  
12

### 13 *Low take up of insurance*

14  
15 Low take up of insurance can be a reflection of lack of perceptions that flood risk is a serious  
16 threat to property and business:  
17  
18  
19

20  
21 *...normally developers and the government are not foolish, they will not put*  
22 *developments into a high (flood risk areas), normally the drainage system is well*  
23 *equipped...(Chinese interviewee).*  
24  
25  
26

27 Alternatively insurance may be unavailable or unaffordable in a particular flood zone  
28 (Germany, Australia). Lack of an insurance policy may be more prevalent in large companies  
29 because while smaller companies may be unwilling to bear risks, large companies can self-  
30 insure.  
31  
32  
33  
34  
35

36  
37 *Supposing they've got, a thousand supermarkets, it'll cost them A\$10 million a year to*  
38 *get .. insurance, they just don't insure, they do a self-insure.... if they lose a supermarket*  
39 *through a flood, they just rebuild/repair it. Each supermarket costs probably less than*  
40 *A\$10 million to rebuild. As long as you don't have more than one flood in your portfolio*  
41 *in a year, you're ahead. (Australian interviewee)*  
42  
43  
44  
45

46 Even in the USA where taking up insurance is encouraged by the NFIP and mandatory in  
47 some circumstances, larger concerns may be underinsured. Commercial coverage through the  
48 NFIP is seen to be too low for many commercial entities, resulting in underinsurance. As  
49 respondents remarked  
50  
51  
52

53  
54 *a lot of deals we do blow past the 500,000 dollar statutory max per building (US*  
55 *interviewee)*  
56  
57  
58  
59  
60

1  
2  
3 *We calculate the amount of insurance a business needs to comply with federal law.*  
4 *Example...\$200,000 loan but building worth \$500,000 – bank only requires \$200,000 ....*  
5 *Can get more but typically only get what is required. No one has ever asked what can I*  
6 *do to lessen my risk. (US interviewee)*  
7  
8  
9

10       Regardless of underlying causes, from a practical perspective, low levels of uptake  
11  
12 subvert the influencing potential of the insurance mechanism. Consequently, some  
13  
14 professionals called for more regulation that includes mandatory flood insurance.  
15  
16

### 17 18 *Lack of premium incentives* 19

20  
21 There was a perception in countries where insurance is widely available that property owners  
22  
23 and occupiers would regard insurance as an alternative to other mitigating action unless they  
24  
25 were able to offset the cost of other mitigation via lower insurance costs. There are market  
26  
27 specific considerations about the practicality of introducing premium incentives. In some  
28  
29 markets, such as the UK, where premium for flood risk is concealed within an all risks  
30  
31 policy, insurers may not be accurately or transparently pricing flood risk. In other countries,  
32  
33 for example the USA, premiums have historically been subsidised, though there is some  
34  
35 movement aimed at reducing or eliminating subsidies.  
36  
37  
38  
39

40 *The pricing of flood insurance sends a signal to do mitigation and if you have a*  
41 *subsidized pricing structure then you aren't sending the mitigation message but if you*  
42 *have more actuarially rated policies then you are sending the message that if you*  
43 *mitigate it can reduce your insurance premium. (US interviewee).*  
44  
45  
46

47 Interviewees recognised that this might be challenging to achieve given the level of  
48  
49 understanding of the impact of mitigation on risk. Although there are several initiatives that  
50  
51 exist or are emerging that could help in the process, currently no professional could identify  
52  
53 such a neutral body and interviewees reflected on a lack of guidance available that insurers  
54  
55 could use to price mitigation efforts.  
56  
57  
58  
59  
60

### *Flood experience and reinstatement*

A commonly mentioned route to influence mitigation occurs during the reinstatement of a property following flood. The reinstatement period is seen as a cost effective opportunity to install mitigation that is also linked to the widely acknowledged effect of flood experience on mitigation. One valuation expert in the US pointed out that a number of commercial entities are retrofitting types of mitigation after Hurricane Sandy. Similarly, following significant flooding in South Carolina in 2015, According to an interviewee:

*I think that is why a lot of people are doing this [mitigation] right now, not so much the insurance side but more the disruption and the down time associated with it. (US interviewee).*

In such circumstances insurers may influence mitigation through information or encouragement of resilient reinstatement. However they may or may not have a role in planning and implementing recovery, particularly within commercial insurance markets where there may be a high degree of financial settlement: *'when I did work in Hull in 2007, people got a flood and never bothered doing any work, they just took the cash'* (UK interviewee).

In any case the costs of risk mitigation are not generally borne by insurers, because terms in insurance generally preclude "betterment", which is defined as the enhanced value of real property arising from local improvements.

*They won't pay for risk mitigation, no. You'll find, with insurance companies, they'll repair what's already there, but if you want to put an improvement scheme in, they won't pay for it. (UK interviewee)*

Insurers may still have the potential to inform policyholders about resilience or to insist on physical resilience measures being installed as a condition of future coverage.

1  
2  
3 *They push back on us saying; "Well what are you doing about mitigating the risk?"*  
4 *Premiums go up, deductibles increase. There's a big focus on what we're doing; to*  
5 *mitigate the cost to the insurer. (Australian interviewee).*  
6  
7

8 With the property owner paying for mitigation an increased interest in undertaking benefit  
9  
10 cost analyses with respect to mitigation of flood risk and insurance has taken place following  
11  
12 flood events in the USA, with an emphasis on how best to reduce future risk. Requirements  
13  
14 for flood insurance have been influential in encouraging mitigation, but the results have been  
15  
16 very context-specific with respect to different business characteristics.  
17  
18

### 21 ***Impact on property value***

22  
23 Interviewees generally concurred that the value of commercial property should be affected by  
24  
25 the level of flood risk. As one commented: *'there has to be a difference in value between a*  
26  
27 *property that floods and one that doesn't'* (UK interviewee). UK valuers also recognised it  
28  
29 was part of their due diligence obligation to consider flood risk:  
30  
31

32  
33 *..So yeah, it is a key consideration for investors and therefore, as valuers, we need to*  
34 *put ourselves in the shoes of those investors and to consider the situation as we would*  
35 *expect them to consider the situation. (UK interviewee).*  
36  
37

38  
39 However, interviewees from all countries felt that the realisation of this discount in market  
40  
41 value is inconsistent due to: lack of awareness or low perception of flood risk; the perception  
42  
43 among multiple stakeholders that flood risk is less important than other property  
44  
45 characteristics; and a lack of guidelines or common practices that allow valuers to factor  
46  
47 flood risk into property value, as described below.  
48  
49

### 51 ***Risk awareness and perception***

52  
53 Interviewees noted that businesses at risk, but not recently flooded, can have low spontaneous  
54  
55 awareness of risk or perceive that the risk is not something they need to be concerned about.  
56  
57 They pointed out that lack of awareness of risk is reinforced if property searches do not result  
58  
59  
60

1  
2  
3 in disclosure and insurance is available regardless of risk. For investment and for business  
4 occupation, valuers' due diligence should result in risk discovery, however a lack of hazard  
5 maps (in China) and shortcomings of accessible hazard information (low resolution and lack  
6 of depth information in UK) as well as difficulties in interpretation (Germany) mean that this  
7 is not always meaningful discovery. In the USA one respondent remarked:  
8  
9  
10  
11  
12  
13  
14

15 *Real estate disclosure laws do more harm than good. People put too much faith in them.*  
16 *Hugely unreliable – usually tailored that only the previous owners' experience has to be*  
17 *disclosed*  
18  
19

#### 20 21 *Other demand factors*

22  
23  
24 Other demand factors were highlighted by interviewees particularly for the case of central  
25 business districts where locational desirability is the dominant consideration.  
26  
27

28  
29 *...I have to mention one thing, because the current office and commercial property are*  
30 *very demanding in Chinese cities like Hong Kong and Shanghai, you can see the*  
31 *commercial property offices emptiness rate is very low especially the grade A and B*  
32 *offices, I believe even if the landlord were to increase the rent because of the insurance*  
33 *and other costs. This will not affect the situation (rental) too much. (Chinese*  
34 *interviewee).*  
35  
36  
37

38  
39 In high risk, high reward locations, no matter what the country, the demand for  
40 property remains strong:  
41  
42

43  
44 *You could have a property that does have an elevated level of risk, but if every other*  
45 *factor is a big tick and there's very few, other options in the vicinity, well you're gonna*  
46 *find a deal that gets done despite the flood risk issue. (UK interviewee).*  
47  
48  
49

#### 50 Similarly in Germany

51  
52  
53 *In Germany there are companies located next to a large river. Despite this, the topic of*  
54 *flooding only plays only a minor role (also for the economic valuation). This is because*  
55 *the markets are so strong, that they consider these risks as unimportant. (German*  
56 *interviewee)*  
57  
58

59 Locational factors cited in the USA included water dependent businesses and the high  
60

1  
2  
3 amenity associated with some areas at risk such as coastal areas. As one professional said:  
4  
5 *‘coastal development is already so rampant here so it’s not like they are going shy away from*  
6  
7 *a project because they are in a flood zone.’* (US interviewee).  
8  
9

10  
11 However interviewees also noted that where choices were available between  
12  
13 properties with high and low risk, the higher flood risk property would be less popular and  
14  
15 valued lower: *‘This means demand for properties in a flood zone is lower than for those*  
16  
17 *behind a flood protection wall, with an appropriate reduction in price.’* (German  
18  
19 interviewee).  
20

21 Different sectors were also regarded as more or less vulnerable to flooding:  
22

23  
24 *The government reclaim some land, they create sort of data centre area, where allocated*  
25  
26 *land for data centre operator, now, that’s interesting because if those data centres are at*  
27  
28 *risk of the coastal foundation of water, ... reducing its value ... massively, because the*  
29  
30 *one you want for the data centre is a safe secure location. If it so close to the water, I*  
31  
32 *think it’s a major major issue.* (Chinese interviewee)

### 33 *Temporal variability*

34  
35 Lack of a structured way to price risk was reflected in the disproportionate reaction to an  
36  
37 actual flood event and the impact of experiencing a flood. For example, one German  
38  
39 interviewee noted that after floods in Germany, *“suddenly disproportionately high value*  
40  
41 *markdowns occur, which are probably not risk appropriate”*. Similarly in Australia after the  
42  
43 2011 Brisbane floods, one interviewee observed that; *“commercial investment slowed in*  
44  
45 *Brisbane after floods, focus was on getting buildings back into operation not sale and*  
46  
47 *acquisition, but people tend to ‘forget’*.  
48  
49

50  
51 A flood event raises general awareness and, more importantly, perception that the risk  
52  
53 is “real” and that the impacts can be severe. This effect was also seen in New York following  
54  
55 superstorm Sandy;  
56  
57  
58  
59  
60

1  
2  
3 *If market participants believe there is a risk then it affects value. For example a shopping*  
4 *centre could be in a flood zone since say 1973 but has never flooded no matter what the*  
5 *risk is, so value isn't affected but one flood can change that. (US interviewee)*  
6  
7

8  
9 Professionals interviewed also indicated that such overreactions can be driven by sharp  
10  
11 increases in property insurance premiums after flooding, especially if some relatively  
12  
13 expensive facilities or equipment are damaged causing unexpectedly high claims:  
14

15  
16 *As far as I know in many cases, if it is needed to repair or fixing a lift/escalator in a*  
17 *commercial building (with 30<sup>th</sup> to 40<sup>th</sup> floors/levels - common height in the Greater China*  
18 *region) will approximately cost at least with \$1 million (or more) Hong Kong Dollars*  
19 *(HKD) (equivalent to £100,000)....(Chinese interviewee)*  
20  
21  
22

23 Disproportionate reaction causes volatility and could potentially lead to blight in less  
24  
25 desirable locations. However, in general the market will return to equilibrium as was reported  
26  
27 in Queensland where a rebound effect occurred, with an economic boost from rebuilding of  
28  
29 0.5% GDP, and also in Germany:  
30  
31

32  
33 *The evaluator will compare the property with comparable transactions in the*  
34 *surrounding area. If there has been a flooding event in the wider area, then the prices*  
35 *will be accordingly low. But if there has not been a flooding event for a longer period,*  
36 *then the prices will go up. (German interviewee)*  
37  
38  
39

40  
41 The consensus is that valuers base their market valuations on the available market  
42  
43 intelligence and that may not reflect actual flood risk.

44  
45 *Appraisers reading the market. Putting together all the data and making judgment of the*  
46 *situation. Not appraiser judging, it is market judging. .... If market not concerned, won't*  
47 *be reflected in appraisal. .... No stigma, no impact (US Interviewee)*  
48  
49

#### 50 51 *Risk information and interpretation*

52  
53 From the investment valuation perspective, a more risk based approach to valuation of  
54  
55 property at risk would be preferred but is dependent on the ability to assess risk accurately.

56  
57 As one valuer described it '*I think the cost of flood insurance in additional costs (affects*  
58 *value), so capitalized insurance costs gets factored into property value'. (US Interviewee).*  
59  
60

1  
2  
3 Availability and cost of insurance are important risk signals but, although insurance is  
4 important in order to facilitate sales and support property value (Kenney *et al.*, 2006), it is not  
5 always rigorously evaluated during property transactions. Evaluation of risk by other means  
6 can be dependent on the impact of regulation and the provision of information about flood  
7 risk, for example in the form of flood zone maps. However, there may be lack of trust in the  
8 maps.  
9

10  
11  
12  
13  
14  
15  
16  
17 *I just ran into a situation where one flood service said the property was not in a special*  
18 *flood hazard zone and another service said it was located in a special flood hazard zone.*  
19 *Data not consistent. And flood zones change. (US interviewee)*  
20  
21  
22

23 Future risk is also important in valuation for investment, however significant uncertainties  
24 surround such estimates. Without reliable and accurate data and projections of risk, some  
25 interviewees are reluctant to disclose flood risk to buyers through concerns of prejudicing  
26 sales. Flood hazard maps have the potential to depress values in areas at risk as in Germany  
27 where one participant observed such an effect after the first round of flood risk management  
28 plans was produced towards the end of 2015 (European Flood Directive 2007/60/EC) .  
29  
30  
31  
32  
33  
34  
35  
36

37 The impact of risk mitigation on value is also unknown with some interviewees  
38 believing a flood event may even have a positive effect on the value of commercial property  
39 if mitigation measures are put in place after the flood:  
40  
41  
42  
43

44 *So if a business, or a commercial property ..could demonstrate that significant flood*  
45 *resistance measures have been adopted. ...., then I'm sure that would have a positive*  
46 *effect on the valuation of the business, or the property itself. (UK interviewee).*  
47  
48  
49

50 However they recognised that the scale and detail of such an uplift are problematic to  
51 estimate in the absence of consensus among the professions or recognition in the form of  
52 insurance discounts. Thus owners and occupiers may be deterred by mixed messages from  
53 different Built Environment professionals, government officials and insurers, and the real  
54 moral hazard where positive action is not recognised by lowering of premiums and inaction is  
55  
56  
57  
58  
59  
60

1  
2  
3 rewarded through compensation.  
4  
5

## 6 7 **Discussion**

8  
9 The findings from the study of commercial property value at risk from flooding and  
10 mitigation through insurance broadly confirms many of the findings previously observed in  
11 the residential property market. These findings relate to a general lack of awareness of risk  
12 (Kreibich, 2011), lack of incentives to mitigate risk through insurance (Kreibich *et al.*, 2007),  
13 lack of understanding of the impact of mitigation and lack of consistency in the reflection of  
14 risk in property value (Hirsch and Hahn, 2017). However there are some significant  
15 differences in the commercial market that require careful consideration.  
16  
17  
18  
19  
20  
21  
22  
23

24  
25 The lack of risk awareness is not only on the part of property owners and occupiers  
26 but includes many professionals that may advise them. Shared understanding of risk is a pre-  
27 requisite for shared understanding of impact and routes to mitigation. Provision of this  
28 information is generally considered to be the role of governments, eg the European directive  
29 (European Flood Directive 2007/60/EC). Raising awareness and generating common risk  
30 perception is also often a governmental goal often delegated to governmental or non-  
31 governmental agencies. Maintaining this awareness is an acknowledged challenge, however  
32 annual reminders through insurance renewal has been proposed as one potential way to  
33 increase saliency. This has significant policy relevance such as opportunities for  
34 strengthening the link between insurance and risk reduction measures (Hudson *et al.*, 2017).  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

48 Findings emphasised the importance of insurance, in keeping with theoretical stances  
49 of insurance as a societal good that covers residual risks and enables recovery (Association of  
50 British Insurers, 2005, Lo *et al.*, 2015). Insurance is also a pre-requisite for due diligence and  
51 therefore a material factor in investment valuations. Interviewees also called for insurers to  
52 do more to incentivise mitigation and this has been discussed in the literature as a way to  
53 avoid increase in societal risk from moral hazard (Kunreuther, 2006). However, while  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 anecdotal evidence of moral hazard exists in the UK recent empirical results from Germany  
4 and the US question the prevalence of such attitudes in the residential sector (Hudson *et al.*,  
5  
6  
7  
8 2017).  
9

10 Interviews indicated that in comparison to the residential sector, penetration of  
11  
12 insurance is lower and commercial property is less likely to have comprehensive coverage for  
13  
14 flood risk, and is more likely to self-insure. This concurs with recent observations in Missouri  
15  
16 (Fell and Kousky, 2015), it follows that the tendency for moral hazard is lower but also that  
17  
18 adverse risk selection may be more likely in commercial premises. Therefore the relevance of  
19  
20 calls for incentives for mitigation through insurance mechanisms in the commercial property  
21  
22 market may currently be seen to be lower than that in the residential sector. Yet, in the USA,  
23  
24 mandatory flood insurance has been seen by some interviewed to have a positive impact on  
25  
26 implementation of mitigation measures despite some limitations in the specific types of risk  
27  
28 mitigation they incentivise. Institutional investors and lenders could have a strong influence  
29  
30 where they are involved (Ball *et al.*, 2002, Teicher, 2018). Therefore while there is evidence  
31  
32 that insurance can play a significant role in encouraging anticipatory flood risk management,  
33  
34 more research is needed in context to understand the way this might provide incentives for  
35  
36 commercial property owners and investors.  
37  
38  
39  
40  
41

42 Lack of consistency is evidenced in valuation of properties at risk within and across  
43  
44 countries and over time. In this respect the commercial property market is similar to the  
45  
46 findings within the residential sector in the UK and Australia (Eves, 2004). The findings also  
47  
48 support studies in the UK regarding commercial property (Bhattacharya-Mis and Lamond,  
49  
50 2015, Bhattacharya-Mis and Lamond, 2016). While the quality of risk information available  
51  
52 to valuers varies, the difficulties previously reported in the UK appear across all countries  
53  
54 studied in terms of understanding how to interpret risk information in order to apply flood  
55  
56 discounts. Sector specific considerations are highlighted with risk largely ignored in the high  
57  
58  
59  
60

1  
2  
3 demand for premium commercial real estate. Different locational factors are offsetting risk in  
4 the commercial sector (eg high street position) than in the residential sector (waterfront  
5 location), although waterfront location is important, indeed vital, for some commercial  
6 sectors. Heterogeneity in the commercial sector adds to the complications in valuation and  
7 mitigation advice. Many interviewees recognised the need to explore mitigation for  
8 commercial property, perhaps as an alternative to insurance or as a means to keep insurance  
9 costs low. This finding sets commercial property apart from studies of the residential market  
10 where insurance or compensation is the more expected approach. The potential to treat  
11 properties on a case by case basis, scale of investment, increased involvement of advisers and  
12 property professionals in the commercial property world may explain this difference.

There were differences in the attitudes expressed in regard to valuation for sale or for investment, more pragmatism is seen on the ground where specific locational or operational advantages offset risk. The study therefore reveals heterogeneity in the approach to valuation due to purpose of the valuation and client goals, as well as in sector and scale of business that the limitations of this study do not allow us to unpick. However the study points to the need to harmonise approaches and increase consistency in order to incentivise mitigation.

## 41 **Conclusions**

The research has highlighted that understanding the link between flood risk, insurance, flood mitigation and property value is important in the maintenance of commercial property value and business prosperity. This is therefore of value to businesses and economies that are threatened by flood risk. It is also of value to investors and their support network of Built Environment professionals in managing sustainable investment portfolios.

While discounting due to flooding, or flood risk, is sometimes observed it is far from universally applied and is often time limited as market value relies on risk perception that varies due to saliency of recent flood experience. Heterogeneity in the commercial property

1  
2  
3 sector and the primacy of business location in certain sectors adds to the difficulties faced by  
4  
5 Built Environment professionals in taking a unified view of risk. There is no consistent  
6  
7 approach that valuation professionals use to reflect flood risk within or across national  
8  
9 markets and therefore investors may need to recognise volatility associated with such  
10  
11 valuations. The use of a cost based approach (estimated damage and loss/cost of  
12  
13 insurance/cost of compliance with codes) may be appropriate, but guidance is needed and  
14  
15 caution needs to be observed in the application of valuation based on rapidly changing risk  
16  
17 designations. The adoption of such guidance may need to be supported by changes in  
18  
19 government regulations on risk disclosure and transparency in insurance regimes.  
20  
21  
22

23  
24 Uptake of flood mitigation measures by property owners and occupiers could limit the  
25  
26 loss and disruption caused by flooding. Furthermore, flood insurance conditions in some  
27  
28 markets were found to be effective in incentivising prescribed measures. However across the  
29  
30 five countries studied, no example was found that provided sufficient incentive for a coherent  
31  
32 programme of risk mitigation for all properties at risk. Government regulations that increase  
33  
34 the uptake of flood insurance or other appropriate risk transfer mechanisms could help to  
35  
36 maintain property value through ensuring adequate funds during recovery and incentivising  
37  
38 mitigation.  
39  
40  
41

42  
43 Lack of risk awareness of professionals and lack of appropriately detailed information  
44  
45 on risk are two further critical barriers that need to be addressed. There are large differences  
46  
47 in the amount and level of detail of risk information available across the countries studied.  
48  
49 Government investment in improved provision and precision of hazard maps would not only  
50  
51 benefit commercial property markets but also flood risk management as a whole. However  
52  
53 Built Environment professionals will need to invest in their own professional development to  
54  
55 interpret and advise on risk.
