### 10 **ABSTRACT**

11 The success of water and energy smart metering is highly contingent on a successful  
12 communication strategy. We report on the findings from a qualitative study involving discourse  
13 analysis of customer messaging and focus groups with utility professionals. Discourse  
14 analysis suggests that the main framings applied are “control”, “convenience”, and “savings”.  
15 Focus groups revealed paradoxes contained in these framings as the participants associate  
16 metering with the loss of control over private data, inconvenience during installation process  
17 and lack of financial gains if customers’ lifestyles cannot support “smart” decisions. Future  
18 communications ought to be tailored to the consumers’ values and needs.

### 19 **Keywords:**

20 smart meters, co-production, climate justice,

### 21 **Highlights:**

22 \*Promotional materials do not reflect the full functionality of metering

23 \*Tariff re-design and transparent communication needed for fair implementation

24 \*Potential for collaboration and mutual learning between water and energy sectors

### 25 **Funding:**

26 The project is jointly funded by the University of the West of England, Bristol City Council and  
27 Lloyd’s Register Foundation, a charitable foundation helping to protect life and property by  
28 supporting engineering-related education, public engagement and application of research.

29 **Conflict of interest:** None. Bristol City Council’s sustainability team is the funder and  
30 stakeholder in the research. However, the role of the council is limited to the provision of official  
31 local government datasets, the funders were not involved in participants’ selection, research  
32 design, data collection or analysis.

### 33 **Abbreviations:**

34 ABC- Attitude, Behaviour, Choice

35 BCC – Bristol City Council

36 DA – Discourse Analysis

37 DSM- demand-side management

38 EU – European Union

39 IHD – In-home Display

40 LSOA – Lower Super Output Area

## 41 **1. Introduction**

42 Meters are devices recording resource consumption at a fine unit of analysis. In their simplest  
43 form, they enable issuing accurate electricity, gas or water billing as opposed to the  
44 approximated statements (DBEIS, 2017b). Their functionality is predicted to increase with the  
45 advance of smart homes and smart grid abilities, however, the current available technology is  
46 at various stages of development and uptake, depending on the location and sector. The

51 devices could provide basic information on the resources consumption or go one step further  
52 and facilitate efficient behaviours. Sovacool et al. (2017) listed 67 anticipated benefits of  
53 energy metering. They included some advanced functionalities, such as: uptake of  
54 microgeneration, easy switching between suppliers, new opportunities for energy storage.

55 Despite the industry promises of improved carbon and water management, the research on  
56 metering as a demand-side management (DSM) tool provides conflicting evidence with  
57 regards to its effectiveness. Metering can only have a positive impact on resource efficiency  
58 provided that it: a) improves the management of the energy grid and tackles water leaks  
59 (Cheong *et al.*, 2015); b) leads to changes at the household level (e.g. decrease in  
60 consumption, purchase of smart equipment, change in social norms) (Bradley *et al.*, 2014;  
61 Buchanan *et al.*, 2014). The extensive literature on climate change communication suggests  
62 that the appropriate engagement strategy is vital for the effective adoption of new technologies  
63 (ibid.)

64 Therefore, the primary aim of the paper is to understand the shortcomings of current smart  
65 meter communications by answering the following questions:

- 66 1. How is metering understood across the water and energy practitioners in Bristol, UK?
- 67 2. What is the role of “sustainability”, “fairness”, and “smartness” in the discourse formation?
- 68 3. How to improve communication materials?

## 69 **2. Theory**

### 70 **2.1. User perceptions of metering**

71 The research is not yet clear on whether metering is an effective tool of DSM – the answers  
72 range from optimistic (Beckel *et al.*, 2014), cautious (Spence *et al.*, 2015; Bradley *et al.*, 2014,  
73 McKenna, 2012) to sceptical (Loftus, 2006). Metering deployment could potentially facilitate  
74 targeted resource efficiency programmes (Beckel *et al.* 2014) and become an essential step  
75 towards the developments of smart tariffs, which could respond to the availability of the grid  
76 and engage with the existing social practices (Torriti, 2017).

77  
78 However, the successful rollout of metering is highly contingent on the interactions between  
79 the users and the technology: the perceptions, communications, design and understanding.  
80 Spence *et al.* (2015) point out current shortcomings in public engagement of DSM. Similarly,  
81 Buchanan et al., (2014) call for a redesign of the current smart meters interfaces, In-Home  
82 Displays (IHD) and McKenna *et al.* (2012) outline the unresolved privacy issues around the  
83 data. Sovacool *et al.* (2017) concluded that social issues like apathy and resistance cannot be  
84 overlooked while dealing with the technical “teething” problems.

85  
86 Since public engagement materials are often the first point of information between the user  
87 and the technology, they have a significant potential to influence perceptions and acceptability.  
88 Previous research exploring customers’ perceptions provides initial recommendations on  
89 future engagement with the “smart” technologies. A survey of over 2400 British householders  
90 concluded that those concerned about the cost are the least likely to accept DSM and share  
91 their data, whereas participants concerned about climate change were more likely to be  
92 supportive of DSM (Spence *et al.*, 2015). Seyranian *et al.* (2015) researched the effectiveness  
93 of public engagement in the water context. They conducted an intervention study of over 370  
94 American households, who received a variety of public engagement materials. The  
95 researchers found that the individuals were most likely to reduce their water consumption if  
96 they received messages related to the social norms and personal values. On the other hand,  
97 the knowledge-deficit approach (i.e. only providing factual information) proved to be the least  
98 effective one (ibid.). More recently, Montginoul and Vestier (2018) conducted a natural field  
99 experiment on 261 French households, testing how communication methods affect smart

100 water metering uptake. Their study resulted in an overall low adoption rate, which was linked  
101 to the lack of incentives, such as “smart” tariffs.

102

## 103 **2.2. Metering as a science-policy issue**

104 Existing experimental studies on metering provide valuable insights into customers Attitudes,  
105 Behaviours and Choices (ABC), however, the ABC approach alone does not answer the  
106 political and ethical questions related to DSM technologies (Shove, 2010). For example,  
107 deployment of metering is closely related to the tariff redesign, which is a contentious issue  
108 both in water and energy industries.

109

110 French energy consumers who discussed the time of use<sup>1</sup> tariffs voiced criticisms arguing that  
111 time of use tariff leaves behind those, who do not have the flexibility to shift their energy use  
112 beyond peak times (Bertoldo *et al.* 2015). The analysis of the Australian block tariffs<sup>2</sup>  
113 concluded that such water pricing was neither efficient nor fair, (Sibly and Tooth, 2014). Loftus  
114 (2006) went even further arguing that the act of water meter installation alone contributes to  
115 the commodification of water, which ought to remain a basic human right. Although an  
116 emerging scholarship describes models for optimal pricing options (Eid *et al.*, 2016; Fahradi  
117 and Taheri, 2017), there are only weak signs of a wider tariff debate among the public  
118 (Hielscher and Sovacool, 2018).

119

120 Another political issue related to metering is the question of governance. Smart meters are  
121 not solely installed to reduce customers’ bills. In fact, many of their predicted benefits relate to  
122 the company savings’ and network improvements, such as reduced operational costs,  
123 enhanced data management or avoided peak demand (Sovacool *et al.*, 2017). Rodney *et al.*  
124 (2018) vision the future of the possible multi-utility service providers synthesising big data on  
125 water and energy use. Helmbrecht *et al.* (2017) argue that smart metering is vital if water and  
126 energy resources were to be managed in integration.

127

## 128 **2.3. Theoretical framework**

129

130 Since fairness and governance of smart transitions are subjects of academic and policy  
131 debates, the would benefit from appropriate theoretical lenses. Sovacool *et al.* (2016) suggest  
132 reframing climate change policies as justice concerns by drawing attention to availability,  
133 affordability, transparency, equity and responsibility of policy decisions. In order to make this  
134 framework operational, the concept of climate justice must be directly addressed at the  
135 policymakers, designers, utilities practitioners and the users themselves.

136

137 Furthermore, an increasing interest in the integrated resources management led to the  
138 development of the Water-Energy Nexus concept, which draws attention to synergies, trade-  
139 offs, efficiencies and potential for collaboration (Hoff, 2012; Rodney *et al.*, 2018; Helmbrecht  
140 *et al.*, 2017). The Nexus agenda is not yet crystallised within the context of UK environmental  
141 management, however its proponents argue that the improved data on water and energy will  
142 lead to integration in policymaking and improved sustainability and security of resources  
143 (Cairns and Krzywoszynska, 2016). In the wake of the urgent challenges such as droughts,  
144 thirsty energy sources (e.g. fracking or nuclear energy), population growth; both Nexus and  
145 climate justice framings could offer novel insights.

146

---

<sup>1</sup>Time of use tariff has different time periods with varying price blocks (e.g. called ‘peak’ weekday evenings or ‘off-peak’ weekend daytime). (CAB, 2017)

<sup>2</sup> Block tariff establishes zero-tariff for consumption up to a certain threshold. The zero-tariff, which equates the household “essential needs”, charges below the real production cost as an incentive for clients to reduce their consumption. Following the zero-tariff block, each successive block is priced higher. The aim of the tariff is to encourage low consumption while reducing the pressure on low-income households (Sibly and Tooth, 2014)

147 Nevertheless, the literature on the practical understanding of climate justice and Water-Energy  
148 Nexus in the context of metering is limited. This paper aims to bridge this gap by exploring the  
149 practitioners' understanding of the concepts like "fairness", "sustainability", "smartness" or "the  
150 nexus" when applied to the smart metering debate.

151

## 152 **2.4. Policy context**

153 Smart metering of the energy sector is a part of the European Commission's recommendation  
154 on energy efficiency 2012/148/EU (European Commission, 2012), subsequently rolled out by  
155 the UK national government (DBEIS 2017b). In the UK, Smart Meters GB is the national  
156 campaign encouraging installation of smart energy meters (Smart Energy GB, 2017).

157 Locally, multiple metering pilot projects were funded in the deprived areas of Bristol, which  
158 suggests that metering could help to tackle fuel or water poverty by encouraging sustainable  
159 behaviours (Connecting Bristol, 2016; KWMC, 2013). However, the potential for an overall  
160 decrease in resource consumption might be limited if the building efficiency is sub-optimal  
161 (e.g. single glazed windows, drafts, leaking taps). Offering behavioural change as a way to  
162 tackle fuel poverty comes with an assumption that people in deprived areas waste energy,  
163 therefore metering could induce behavioural change (Shove, 2010). The local data on energy  
164 use suggests otherwise – people in 10 most deprived areas consume far less gas compared  
165 to their more affluent counterparts (Table 1).

166

Mean gas consumption	
Average from 10 most deprived LSOAs (kWh/meter)	Average from 10 least deprived LSOAs (kWh/meter)
9176.4	17245.1

167 *Table 1. Average mean gas consumption in 10 most and least deprived LSOAs in Bristol in*  
168 *2015 (raw gas consumption data from DBEIS, 2015a; deprivation data from BCC, 2015)*

169 In contrast, measuring water consumption and upgrading the "grid" from analogue to smart  
170 metering is not a current policy priority in the UK (Priestley, 2016). In fact, it is estimated that  
171 a half of the UK population does not have a water meter, in which case their water bill is  
172 decided by the so-called "rateable value" of the property – an estimation of a rental value of a  
173 property in 1990 (Bennett, 2013). Compulsory universal water metering has so far only been  
174 introduced in parts of the UK subjected to the highest water stress (i.e. south-east England).  
175 However, many English water companies see metering as a useful tool for resource  
176 management and are compelled to promote it to their customers (Priestley, 2016).

177 Similarly, the water dimension is mostly absent from smart and green policies at the urban  
178 scale. This might be due to the fact that water efficient behaviours and infrastructure are  
179 largely outside of the remit of the local authorities. In the UK, the water sector is privatised and  
180 regionally monopolised, which hinders access to data, knowledge transfer and cross-sectoral  
181 governance (Loftus *et al.*, 2016).

## 182 **3. Methods**

### 183 **3.1. Methodology framework**

184 The researchers adopted a knowledge co-production approach, combining two qualitative  
185 methods: discourse analysis of metering promotional materials and two focus groups with  
186 metering experts. Co-production emphasises the deeper involvement of non-academic actors  
187 in the research process (Jasanoff, 2010). In this case, participants selected the focused  
188 research question ("communication strategy") after being presented with the wider theme

189 (“water and energy meters”). The paper authors conducted the first iteration of data analysis  
 190 and presented the results for further discussion during the participants’ meetings and a free  
 191 public event organised by the Bristol Energy Network<sup>3</sup> in July 2018.

192 Co-producing research with public, private and charity sectors is useful for capturing different  
 193 discursive framings, cross-sectoral learning and creating future opportunities for collaboration.  
 194 Furthermore, it facilitates an active deliberation on policy recommendations (Howarth and  
 195 Monasterolo, 2016). Conducting qualitative and participatory research together with both  
 196 water and energy metering experts complements currently prevailing quantitative and natural  
 197 sciences approaches to the Water-Energy Nexus issues (Albrecht *et al.*, 2018).

198 The research was held between June 2017 and July 2018 and it involved the following stages:

- 199 • Literature review of the smart metering scholarship and policy context (Section 2);
- 200 • Discourse analysis (DA) of metering promotional materials from four organisations  
 201 (Section 4.1);
- 202 • Thematic analysis of two focus groups (Sections 4.2-4.6.);

203 **3.2. Discourse analysis of promotional materials**

204 The notion of the discourse describes the sum of communications on a particular topic: the  
 205 language, form, images, metaphors and arguments used. Discourses, especially if written by  
 206 authorities (in this case policymakers, experts or utility providers), indicate what can and  
 207 cannot be expressed or challenged by the audience – which information is seen as a “fact”  
 208 and which is open to a dispute (Bax, 2011). DA critically unpacks the current debates in the  
 209 areas of water and energy metering in order to evaluate whether and how sustainability,  
 210 smartness and climate justice ambitions are embedded in the promotional materials.  
 211 Documents selected for the analysis were websites and online leaflets providing information  
 212 and promoting metering in the water and energy sectors. The researchers selected four  
 213 sources from two key local service providers and two national-level organisations overseeing  
 214 metering deployment. The researchers thoroughly analysed each document to unpack the  
 215 rhetorical and linguistic tools used. For example, they looked to determine the overall tone of  
 216 the message (e.g. promotional, informational), arguments fore- and backgrounded (e.g.  
 217 placed in the title vs at the bottom of the page), and the main frames applied (e.g. savings,  
 218 sustainability, control). Table 2 lists the documents analysed together with the heuristic for the  
 219 process (adapted from Bax, 2011).

Documents analysed	Description of organisation	Heuristic
Ofwat (2013) Water meters- your questions answered <a href="https://www.ofwat.gov.uk/wp-content/uploads/2015/11/prs_lft_101117meters.pdf">https://www.ofwat.gov.uk/wp-content/uploads/2015/11/prs_lft_101117meters.pdf</a>	National water industry regulator	<ul style="list-style-type: none"> <li>• Location in the text (e.g. title/ front page/ last page)</li> <li>• Aim (e.g. inform/ promote)</li> <li>• Main framings used (e.g. savings, convenience, control)</li> <li>• Unchallenged assumptions?</li> </ul>

--	---	---

220 *Table 2. List of documents analysed and a heuristic for DA.*

221 **3.3. Focus groups**

222 If DA intended to understand how utility providers construct their engagement, focus groups  
 223 aimed to clarify metering professionals regard metering as a “sustainable”, “fair” and “smart”  
 224 tool of DSM. In doing so, the discussions explored the understanding of the purpose and  
 225 potential of metering across the utilities professionals in Bristol, UK. Environmental policies do  
 226 not arise in a conceptual vacuum, they are a result of debates between stakeholders across  
 227 the sectors, who build trust and rapport while deliberating on their language and goals (Harris  
 228 and Lyon, 2013).

229 Following the exploratory part of the event, participants discussed the recommendations for  
 230 the policy and public engagement. Focus group was deemed an appropriate method for this  
 231 research, as it taps into the interactions between participants, observing the process of  
 232 discourse formation, agreements and disagreements (Morgan, 1998). This is particularly  
 233 relevant for the policy issues, which are commonly co-produced in collaboration between  
 234 private, public and charity sectors (Howarth and Monasterolo, 2016; Harris and Lyon, 2013).

235 The following paragraphs outline the research design. First, the researchers identified key  
 236 local organisations with experience in water and energy metering. Then, they approached  
 237 eligible organisations and purposively selected participants, so that the group composition  
 238 achieves the diversity of sectors and roles. As a result, the researchers conducted two focus  
 239 groups, with 6 participants in each (Table 3).

Focus group 1		Focus group 2	
Participant	Sectors	Participant	Sectors
FG1_P01	Energy researcher	FG2_P01	Water company
FG1_P02	Civil Servant (Smart Futures)	FG2_P02	Energy company
FG1_P03	Energy Company	FG2_P03	Community Energy (Local Project)
FG1_P04	Water Company	FG2_P04	Community Energy (Network)
FG1_P05	Water Researcher	FG2_P05	Civil Servant (Household Resource Efficiency)
FG1_P06	Community Energy (Network)	FG2_P06	Water researcher

240 *Table 3. Focus groups participants*

241 The discussions lasted 1.5 hours each, which included both pre-scripted questions and the  
 242 critique of existing metering promotional materials (i.e. documents specified in Table 2). The  
 243 researcher-facilitator focused the discussion on the purpose of metering, biggest challenges,  
 244 cross-sectoral learning and recommendations for communication. In order to establish a  
 245 sense of shared language, the researcher-facilitator asked the participants to discuss the  
 246 terms commonly used in their roles, such as “sustainability” or “fairness”, “smartness”.

247 The focus group data were audio recorded, transcribed and examined using thematic analysis.  
248 The method allows capturing patterns and grouping complex qualitative data (Braun and  
249 Clarke, 2006). First, the data were analysed at the descriptive level, establishing codes derived  
250 from the questions (e.g. “solutions”, “challenges”, “purpose of metering”). Then, after an in-  
251 depth reading, the interpretive and analytical inductive codes were captured to compose a  
252 thematic narrative present in section 4.

## 253 **4. Results and discussion**

### 254 **4.1. Discourse analysis of marketing materials**

255 The researchers analysed four customer-oriented documents on metering from the following  
256 organisations: Bristol Water, Ofwat, Bristol Energy, Smart Energy GB. The themes prevailing  
257 in the metering promotional materials are “control”, “savings” and “convenience”, as these are  
258 the keywords appearing most commonly in each document, often on the first page or written  
259 in a bigger font. The messages emphasize that the customers will be able to gain control over  
260 their energy use (*“Using in-home display will give you a greater understanding of what you’re*  
261 *spending”* Bristol Energy, 2016) and therefore lower their bills as a result of meter installation  
262 (*“You could save up to £100 on your water bill”*; Bristol Water, 2016). The leaflets also  
263 emphasize the ease of installation process and the convenience benefits resulting from having  
264 a meter (*“No more having to read the meter or trying to work out your bill. No more strangers*  
265 *coming into your home for meter readings”*; Smart Energy GB, 2017). However, despite the  
266 commonalities, there are significant differences in communication, depending on the sector  
267 and organisation.

268 Smart Energy GB repeatedly uses the discourses of control, savings, and convenience –  
269 notably, these are all benefits to the individual. Even the title of the leaflet – *“The simple way*  
270 *to control your energy use”* – is meant to evoke the above qualities. When justifying the rollout  
271 in the further paragraphs, the organisation provides the context of the EU-led regulation  
272 implemented in the interest of mitigating climate change and upgrading the energy grid. It is  
273 worth noting that the reasons for policy implementation are not located on the landing page or  
274 the front of the leaflet, suggesting that the benefits to the environment and the energy sector  
275 are backgrounded from the promotional strategy.

276 Similarly, Bristol Energy uses the discourses of “control” and “savings”. In addition, they  
277 emphasize the environmental and fairness values from the beginning, providing a more  
278 collectivist justification of metering. Their messaging is characterised by a level of  
279 transparency and honesty – owning a meter will not make a difference, engaging with it –  
280 could do so.

281 *“It’s important to note that just by having a smart meter and in-home display,*  
282 *you’re not automatically going to use less energy and start spending less*  
283 *money, but these devices put the power in your hands. Using in-home display*  
284 *will give you a greater understanding of what you’re spending, identifying when*  
285 *you use the most energy and highlighting in near real-time the way you use*  
286 *energy in your home”*. (Bristol Energy, 2016)

287 Bristol Water focuses their messaging on savings and the ease of application and installation  
288 process, both benefits to the individual. Additionally, one of the benefits of metering outlined  
289 on the landing page is *“it helps us to detect leaks much quicker”* (Bristol Water, 2016), an  
290 advantage to the industry. However, this point is not elaborated further in the document. The  
291 Bristol Water leaflet contains presumption about customers’ attitude to water (*“Most of us do*  
292 *everything we can to save water, we know it’s important to everyday life”* Bristol Water, 2016).  
293 Further pages of the document explain how the metered water bill might change, revealing

294 that it is, in fact, a function of a number of householders, number of the rooms, personal water  
295 usage and the presence of the garden. The final page of the leaflet contains an application  
296 form asking questions like *“Is there an externally located stop tap controlling water to the*  
297 *property? Do you share water supply with your neighbour?”* (Bristol Water, 2016). There is no  
298 evidence whether the above questions are easily answerable by an average water customer,  
299 indicating that the application process might not in practice be perceived as “easy”.

300 The communication prepared by the industry regulator, Ofwat, has an entirely different  
301 character as it is informative and explanatory rather than promotional. Ofwat justifies metering  
302 as an environmental and strategic intervention, aiming to improve the management of scarce  
303 water supplies and increasing demand as a result of population growth. The document aims  
304 to improve the bill literacy, providing a comparison of water tariffs in the unmetered vs metered  
305 scenarios. It then reports that *“some people regard meters as the fairest way to charge for*  
306 *water and sewerage services. This is because you pay for how much water you use”* (Ofwat,  
307 2013). However, Ofwat does not comment on this opinion nor elaborates why other water  
308 tariffs would not be as fair.

309 The main difference between the leaflets is the inclusion of individualist versus collectivist  
310 arguments. The second difference is between informational versus promotional character of  
311 the marketing materials. Notably, the individualist arguments were commonly presented in the  
312 promotional materials, whereas collective reasoning was included in the informational  
313 materials. However, it should be noted that on a few occasions, the messages managed to be  
314 *both* promotional and informational as well as contain *both* individualist and collective  
315 arguments, e.g.:

316 *“Smart meters are part of the government's plan to bring our energy system*  
317 *up to date. By 2020, every home in Great Britain will be able to use smart*  
318 *meter technology to see exactly how much energy they're using, and what it's*  
319 *costing in pounds and pence. In addition to these immediate benefits, the*  
320 *rollout also lays the foundation for Great Britain's move to a lower carbon*  
321 *economy and a secure energy supply”* (Smart Energy GB, 2017)

322 Combining a range of arguments and communication styles results in the honest and  
323 transparent disclosure about the limits and the potential benefits of metering.

#### 324 **4.2. Theme 1: Misplaced aims**

325 DA of promotional materials revealed that meters are commonly promoted under the  
326 discourses of convenience and control. Yet, five focus groups participants reported that the  
327 customers frequently perceive the installation process as an inconvenience, which is seen as  
328 a major barrier to the uptake. Not only participants referred to what they imagine “lay”  
329 customers think (recorded 12 times). In fact, focus group members, all with professional  
330 expertise in metering, recalled their *own* experiences as energy customers (recorded 6 times):

331 *“My energy company contacted me, and their letter was “we need to turn*  
332 *every appliance off in your house” - but I don't want to. I had an argument*  
333 *with that woman for 15 minutes, because I just don't want one...as a*  
334 *consumer I have that choice”* (Water Company)

335 Similarly, the discourse of control over energy and water use stands in contradiction with the  
336 perceived loss of control over privacy and data (recorded 16 times): *“With water 2/3 of water*  
337 *consumption is done in privacy and in a bathroom and maybe you don't want people to know*  
338 *what your bathroom habits are”* (Water academic). On the other hand, ensuring adequate  
339 privacy settings could pave the way for the innovative ways of engagement, such as data  
340 visualisation or competitions with incentives.

341  
342 *“If you want people to engage and to know what their data mean, then having*  
343 *them compete with other members of their family or the friendship group*  
344 *takes that ownership away from the organisational structure, but it does*  
345 *actually create a real engagement that may last a lot longer than anything*  
346 *that comes top-down” (Water Company)*  
347

348 Water and energy sectors would have to consider at what level the data are gathered (e.g.  
349 person, household, LSOA, city) and whom they are shared with (e.g. utility company, the  
350 government, academics, advertisers). In its current state, the privacy settings hinder  
351 accessing, analysing and visualising data which could be useful for effective public  
352 engagement. If water and energy sectors are serious about working on the nexus issues, they  
353 ought to consider the trade-offs between data privacy and data accuracy.

354  
355 *Community Energy 1: If there was a target for Bristol average per capita*  
356 *consumption for water then you see where you are comparing to the*  
357 *average.*

358 *Water Company: We do this.*

359 *Community Energy 1: Oh, you do?*

360 *Community Energy 2: Do you include that information on your customer*  
361 *sheet?*

362 *Water Company: We don't do it at the moment, largely because we don't*  
363 *know how many people are in the house.*  
364

365 Participants admitted that the promotional strategies are yet to address the above issues, and  
366 the issue of right communication deserves further research. Since the customers have not  
367 received convincing arguments, they do not have the reason give up their data privacy:

368 *Energy company: I think the energy industry as a whole hasn't really made*  
369 *a good enough offer to people...A really good offer, a really good service,*  
370 *as long as they give away a certain amount of their data privacy around*  
371 *their energy consumption. That's the exchange that people can understand,*  
372 *can opt into...*

### 373 **4.3. Theme 2: Intelligent choices**

374 The purpose of metering, as explained by the participants, turns out to differ significantly from  
375 the justification provided in the promotional materials. Participants agreed that “smartness” is  
376 about enabling “intelligent choices” – both for the customers and the industry (recorded 13  
377 times): *“I'm just going to get a highlighter pen and put “intelligent choices”, I'd highlight that bit,*  
378 *because I think that unless you're using it to inform decision making then it's not smart, then*  
379 *it's just measuring stuff...”. (Energy Researcher). In fact, the “convenience” and “savings”*  
380 *arguments have been explicitly categorised as “not smart per se”.*

381  
382 Water participants focused on the industry's intelligent choices, *“We can spend millions of*  
383 *pounds replacing pipes but if we have no idea where the water is going... the data is far more*  
384 *important to make those informed decisions” (Water Company). In turn, energy participants*  
385 *emphasized the potential to make “smart decisions” on the street or neighbourhood level,*  
386

387 *“What you could potentially do on a street level is a demand-side response.*  
388 *So if there are particular times of the day, where there is a particularly high*  
389 *demand on the grid, you could aggregate the energy from a collection of*  
390 *houses and decrease the consumption based on turning on and off*  
391 *appliances. And if you can pull that into a street or a neighbourhood,*

392 *suddenly you have an economic value to that, an excess energy that you can*  
393 *then sell back to the grid". (Energy Company)*

394

395 Although the implementation of smart meters is a matter of national legislation, the emerging  
396 technologies and users' experiences are often tested at a neighbourhood level. Such pilot  
397 projects are usually coordinated by the local actors, such as researchers, local authorities or  
398 utility companies. Participants reflected on their recent work in this field, which enabled them  
399 to test the potential for "*intelligent choices*" in metering. Local initiatives recalled during the  
400 focus groups were: [Replicate](#), [CHEESE](#), [Smart Spaces](#), [Owen Square Community Energy](#),  
401 [UWE Student Accommodation Water Strategy](#). The highlighted lessons learnt from the past  
402 projects were:

- 403 • The question of the capacity to change lifestyle and purchase smart products in  
404 disadvantaged households;
- 405 • The need for the re-design of energy tariffs to e.g. block pricing or time-of-use tariff.

406

407 Gathering fine level data on energy and water consumption is essential for the introduction of  
408 smart tariffs, however, the technology alone does not guarantee that all customers will benefit  
409 in an equitable way: "*One flipside of 'smart' to be aware of, the potential for that not to be fair...  
410 and to actually just privilege people who are more tech-savvy or who have the ability to  
411 organise their lifestyle*" (Energy Company). Participants are already aware of the potential for  
412 injustices once smart energy and water meters are widespread. To counteract this, they focus  
413 the current efforts on piloting metering among deprived communities. However, the  
414 conundrum remains: even the best design of IHD and most innovative tariffs will not lift people  
415 out of fuel and water poverty, if these residents do not have the capability to make changes to  
416 their lifestyles, e.g. due to illness, shift work pattern or short term renting contracts.

#### 417 **4.4. Theme 3: Focus on the needs**

418 Meters have been originally designed as the technology facilitating energy and water  
419 efficiency, and therefore sustainable management of environmental resources. Throughout  
420 the discussions, participants emphasised the need to reconcile "*sustainability*" and "*fairness*"  
421 agenda (synonyms of "*fairness*" were recorded 57 times). However, there are potential  
422 complications as these agenda serve two different types of customers and need two tailored  
423 policy approaches accordingly. One of the participants suggested: "*One of the ways to look  
424 at it, that there are two markets, there's early adopter market and what we call vulnerable  
425 households in the industry*" (Energy Company).

426 Metering alone does not tackle fuel and water poverty. Yet, reducing resource consumption  
427 among the affluent residents is essential for meeting the climate mitigation targets.  
428 Participants brought attention to this paradox and suggested cross-subsidising and explicit  
429 differentiation between these two markets while designing policies and public engagement.

430 *"The contradiction is – we actually need the early adopters, we need the*  
431 *people who don't need to worry about the bills, otherwise we won't have the*  
432 *technology available for the lower retail cost in place. Then the early adopters*  
433 *can cross-subsidise a charitable project that will sort out the mess of fuel*  
434 *poverty and water poverty."* (Civil Servant)

435 There are numerous ways to conceptualise the "social" side of meters, with terms like social  
436 justice, equality, inclusion, vulnerability, class used interchangeably. The discussion, however,  
437 would always eventually refer to defining, measuring and providing for "the basic level of  
438 need". e.g.:

439 *“Just to tie it back to sustainability issues, one the possible benefits is that*  
440 *metering is, you can then say, ‘here is the **social amount** that someone would*  
441 ***need** for the social use level that we think we would price it to the lower level’,*  
442 *so you’d have that block pricing, and then you’d charge extra” (Energy*  
443 *Researcher)*

444 Framing metering as a technology helping to define, measure and provide for the basic level  
445 of need led to a discussion about appropriate tariffs and universal water metering. Community  
446 Energy, Water Researcher and Water Company participants disagreed on the perceived  
447 fairness of block tariffs. Although such pricing structure could include the notion of affordable  
448 water to cover the basic level of need, it is not clear how the “basic level of need” would be  
449 determined: *“My problem with block pricing is...and actually, I have quite a big problem with*  
450 *it... which is that it means that I get to decide what somebody else needs and why the hell*  
451 *should it be up to me?” (Water Company).*

452  
453 Considering the introduction of the universal water metering calls for a debate on the  
454 relationship between the people and water. Although water metering is promoted as the  
455 “fairest way to pay” (section 4.1), one of the participants pointed out that the current tariff  
456 based on rateable value is more affordable: *“People who don’t have a water meter, pay [bills]*  
457 *on the rateable value of their house, and there is an element of **affordability** in that, the*  
458 *assumption that if you live in a smaller house, that is of a lower rateable value” (Water*  
459 *Researcher).*

460  
461 Nevertheless, as one of the participants stated, *“water is sort of fundamental, you need to*  
462 *drink” (Civil Servant).* Access to clean water and sanitation is recognised as a human right by  
463 the United Nations (UN, 2010). Re-designing the tariffs using the data obtained from metering  
464 provides an opportunity to introduce fair, transparent and data-supported policies, which would  
465 recognise water as a “human right” as well as “scarce resource”. However, before metering  
466 could help to determine “fair” water tariffs, the industry ought to collect baseline data and deal  
467 with leaks. One participant admitted: *“I’d quite happily meter everybody with intelligent meters*  
468 *and not charge people against the meter, it’s so just we have the data.” (Water Company).*

#### 469 **4.6 Theme 4: Tailored communication**

470 The discussions on the purpose and potential of metering concluded with recommendations  
471 for public engagement. Given the observation that there are (at least) two markets of  
472 consumers affected differently by metering (section 4.4.), future communications could reflect  
473 their needs, values and priorities:

474 *Water Company: I am motivated to save water because of my personal*  
475 *commitment, that’s not normally the case for people who can easily afford*  
476 *something. So I am interested in how you can engage with people on*  
477 *perhaps values-based basis.*

478 *Community Energy: I’d say that’s exactly the same problem with energy,*  
479 *when we’ve done the studies where there are the wealthiest communities*  
480 *that are spending the most on their energy bills, but they’re not caring about*  
481 *it.*

482 Since Community Energy, Local Authority and Water Company participants agreed that  
483 metering alone would not reduce resource consumption, they suggested that public  
484 engagement should come in a “support package” form, together with tailored advice on smart  
485 appliances and appropriate building level schemes tackling draft and leaks at vulnerable  
486 households:

487           *“You can make things visible to people, but if you just make more*  
488           *problems visible to them, you're adding stress so you're making their lives*  
489           *worse. If you offer support, like you both suggested [pointing at other*  
490           *discussants], it goes alongside that awareness raising. Smart metering*  
491           *needs to have that support package explaining how you can be a part of*  
492           *it and how you could benefit” (Community Energy)*  
493

494 Finally, six participants collectively critiqued the framings present in the current marketing  
495 materials and pointed out that the main priority is to create a compelling narrative, which refers  
496 to both individual and collective benefits (i.e. to the planet, society and service providers) of  
497 metering and smart technologies. *“Starting with a person and then through the narrative*  
498           *coming to the community, I think that's when the marketing drive needs to be a bit personalised*  
499           *to the individual, but then stepping up...so the context and the country and then the planet”.*  
500 (Community Energy).

501

#### 502 **4.7. Critical reflections**

503 The qualitative methodology, small sample size and geographic scale of the study suggest  
504 high contextuality of the results and point at the need for further research exploring different  
505 locations and organisations. Nevertheless, findings from the study provide valuable insights  
506 into the knowledge co-production approach. Detailed heuristics and critical reflections on  
507 discourse analysis, focus group recruitment and data analysis will facilitate reproducing results  
508 in future studies. Furthermore, validity and accuracy of the research were enhanced by  
509 combining two methods and sampling participants across a variety of sectors (Harris and  
510 Lyon, 2013).

511 By conducting cross-sectoral focus groups, the research informed the debate on metering,  
512 which usually takes place in sectoral siloes, separating practical and academic knowledge  
513 from each other. Hoolohan and Browne (2016) pointed out that the limited occurrences of  
514 participatory and deliberative methods deprived utility sectors of creativity essential for the  
515 introduction of the innovative DSM tools. In order to ensure inclusivity, further research on  
516 metering ought to tap into experiences of a wide variety of users and bring explicit attention  
517 into the notions of “smartness”, “sustainability” and “fairness”.

518 Despite their narrow geographical focus, the research outcomes are internationally relevant  
519 due to the ongoing rollout of smart technologies across the EU member states. Although the  
520 smart technologies advanced considerably over the past years, the EU member states are yet  
521 to understand the interplay between promotional strategies, sustainability/justice discourses  
522 and the future smart tariffs. Further research on the interactions between smart technologies  
523 and people could shed the light on the issue of the interplay between smart meters and user  
524 experiences.

525

#### 526 **5. Conclusions**

527 By way of discourse analysis and focus groups, this paper unpacked assumptions and  
528 contradictions, which energy and water sectors have with regards to metering. The research  
529 found disparities in the customer-facing messages and perceived functionality of meters. First,  
530 the argument of metering as tools for “convenience” does not reveal much about the  
531 functionality of smart meters and it stands in opposition with the in-convenience experienced  
532 during the installation process. Furthermore, metering is advertised as a tool ensuring “control”  
533 over consumption, however, the utilities’ professionals signal that the lay users tend to  
534 perceive “loss of control” due to potential privacy issues. Similarly, despite the industry  
535 promises of “fairness” and lower bills, metering would not address the issues of water and fuel

536 poverty if deployed without the adequate public engagement, tariffs and support package. The  
537 research demonstrates that although practitioners across the public, private and community  
538 sectors highlight the imperative of “fair tariffs” and meeting “the basic level of need”, the policy  
539 provision is yet to frame the above as a climate justice concern.

540 The analysis of research data concludes with the following recommendations for customer  
541 communication: a) a transparent and honest public engagement strategy which would refer to  
542 the full functionality of metering, the long-term ambitions of tariff re-design and benefits to the  
543 utilities sector; b) communication materials tailored to consumers’ values and needs; c)  
544 metering deployment supported by a whole package of policy and communication, which  
545 includes advice on subsidised efficiency schemes at the building level. Only tailored and  
546 comprehensive policy design would reflect the reality of two distinct markets: early adopters  
547 and vulnerable households.

548 Finally, organising focus groups with both energy and water sectors professionals working for  
549 a variety of organisations created a novel space for engagement across the domains of Water-  
550 Energy Nexus. Synthesis of secondary data reveals that although water and energy meters  
551 occupy different policy areas, they are both fundamentally concerned with the same issues of  
552 improved efficiency and fair provision. It can be therefore concluded that the nexus-type  
553 integrated decision-making has a chance to develop, provided that further collaborations and  
554 data sharing agreements will arise between utilities, academia and the government.

## 555 **Acknowledgements**

556 Many thanks to the research participants for their time, inputs and willingness to share data  
557 and disseminate the results.

558 We would like to thank the staff and volunteers of the Bristol Energy Network who facilitated  
559 the discussion of the draft results during internal meetings and a public-facing event.

560 Finally, we would like to thank our anonymous reviewers to their valuable suggestions on the  
561 manuscript.
