Downstream migration
of 2+ Salmon smolts
(*Salmo salar*) in the
river Meuse in the
Netherlands.

André Breukelaar (RWS WNZ)
Tim Vriese (ATKB)
Harriet Bakker (RWS ZN)

Aim of the study

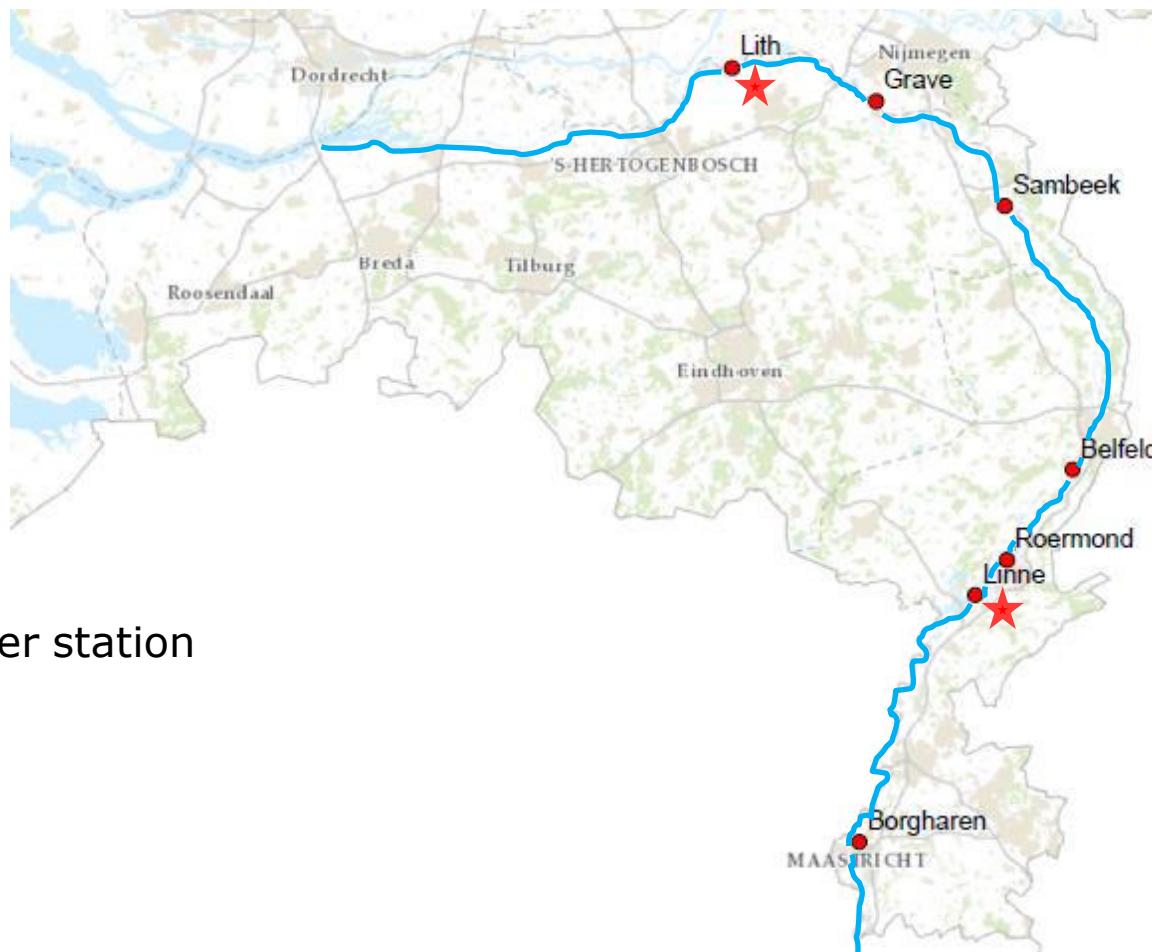

- To gain insight in the migration of Salmon smolts in the river Meuse, to determine choice of route and migration speed of individual fishes in relation to river discharge and other factors;
- To obtain a reliable estimation of the average mortality of Salmon smolts during downstream migration in the Dutch part of the river Meuse
- To quantify direct and indirect mortality of smolts passing hydropower stations and weirs.

This knowledge helps to formulate suitable measures to facilitate fish migration at barriers like hydropower stations and weirs, to protect fish in general and to support decision making in the process of licencing hydropower stations.

Weirs and hydropower stations in the river Meuse

Results migration of smolts 2009-2013

- In total 897 smolts were released at two different locations in the river Meuse (near Belgian border and 56 km downstream)
- At location Linne, 192 smolts passed through the hydropower station and 144 smolts passed over the weir in downstream direction.
- In the downstream river stretch from Linne to Lith (126 km), 52% of the smolts that passed through the hydropower station Linne were lost, compared to 42% of the smolts that passed over the weir

Migration of smolts 2009-2013

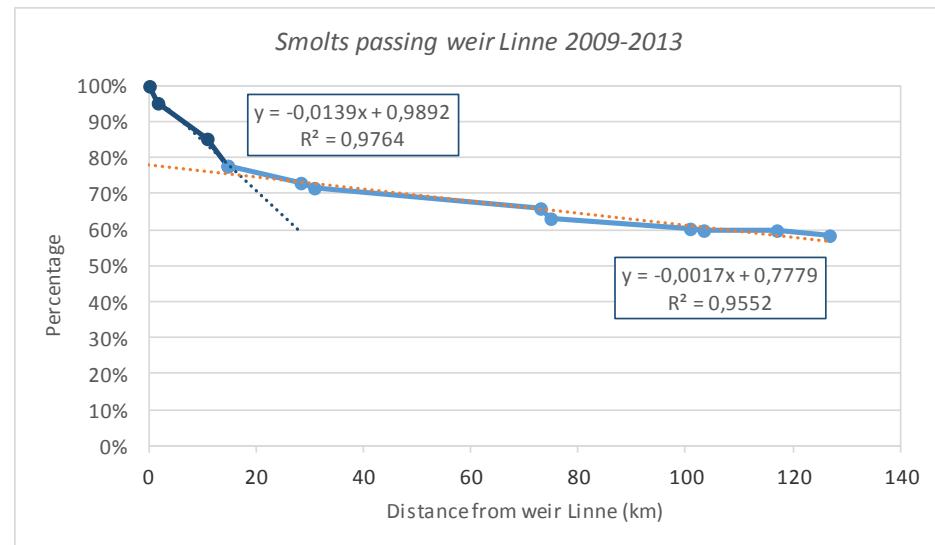

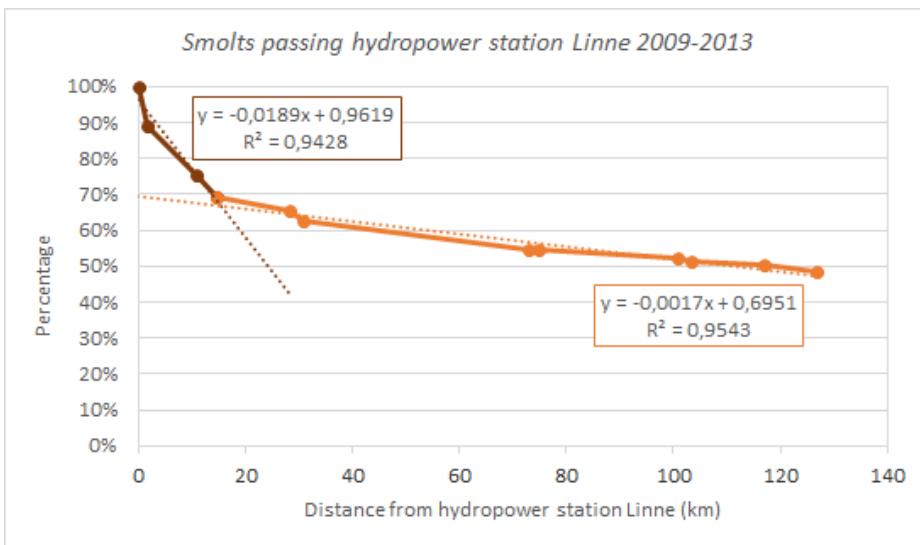

Linear regression shows no significant difference in mortality rate of smolts passing through the hydropower station and smolts passing over the weir.

Migration of smolts 2009-2013

Segmented linear regression shows significant difference in mortality rates over the first stretch after passing hydropower station and weir, compared to the latter part of the route to sea.

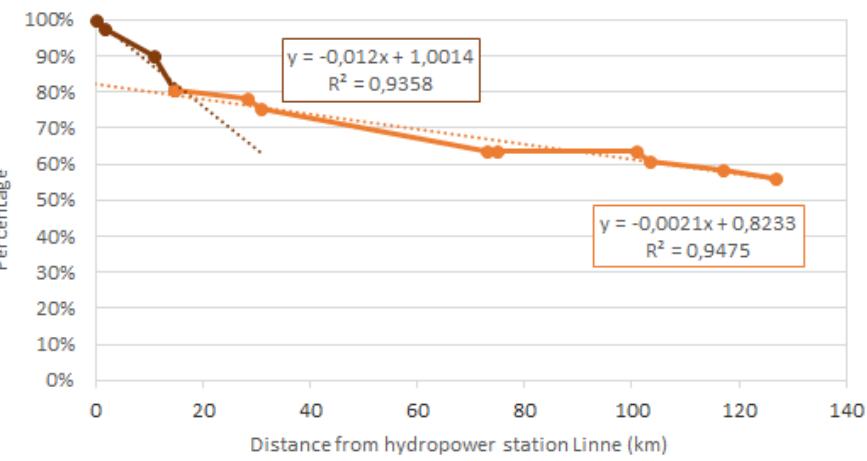

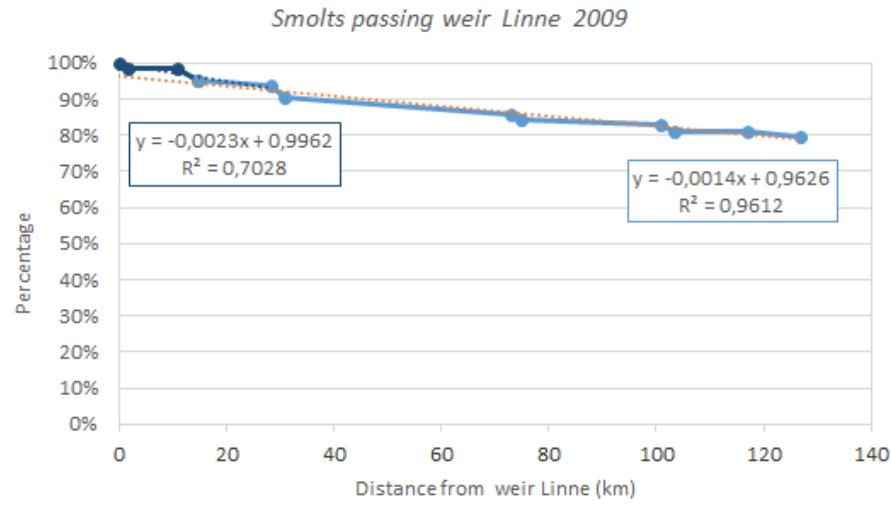

Migration of smolts 2009

Segmented linear regression in 2009 shows a higher mortality rate of 'hydropower smolts' compared to 'weir smolts', but only over the first river stretch (15 km)

Smolts passing hydropower station Linne 2009

Smolt migration in 2013

Conclusions

- In all relevant years, mortality of smolts is higher when passing through the hydropower station compared to passing over the weir:

2009: 48% hydropower smolts, 25% weir smolts (+23%)
2010: 37% hydropower smolts, 31% weir smolts (+8%)
2013: 65% hydropower, 54% weir smolts (+11%)
- The mortality rate of smolts is increased in the first 15 km downstream the hydropower station and weir. More downstream mortality rate is lower.
- An increase of river discharge seems to stimulate the migration.

Thanks for your attention!
