A third set of attributes (designated by  $C_1 \ldots C_p$  in Equation 3) would have a common value for the entire Blackfoot River watershed. Since they are constants for this study, the items listed in Table 22 are only proposed for use in assessing the applicability of the relationships reported in this study to other locations and were not quantified. Certain regional attributes defined on Table 23 are particularly relevant to estimation of an amount of use occurring in the study area (Table 22) and others are particularly relevant to estimation of the impact of the use that does occur on public concerns (Table 24). These two tables suggest relationships deserving further analysis.

## Spatial Patterns of Use

The spatial patterns of the 21 uses are determined by choices made by users reacting to site attributes. Uses concentrate in favorable areas and avoid unfavorable ones. The 21 uses listed in Table 7 and whose estimated total magnitudes for the study area are enumerated in Table 9 and were disaggregated into use estimates for 1980 for each of the 343 land planning units shown in Figure 5. The disaggregation methods varied from use to use as follows:

|     | Uses                                |     |     | Att | ributes |
|-----|-------------------------------------|-----|-----|-----|---------|
| Т.  | Commercial logging                  | A2  | A3  | A4  |         |
| 2.  | Firewood cutting                    | A3  | Α4  | A7  | A13     |

Table 17. Identification of reasonable uses by land unit.

0 - Use is not reasonable

1 - Use is reasonable
\* - For use 11, 2 is reasonable for both hiking and dispersed camping, 1 is reasonable for one of the two, 0 is reasonable for neither.

•

Table 17. Continued.

•

0 - Use is not reasonable
1 - Use is reasonable
\* - For use 11, 2 is reasonable for both hiking and dispersed camping, 1 is reasonable for one of the two, 0 is reasonable for meither.

Table 17. Continued.

~

0 - Use is not reasonable
1 - Use is reasonable
\* - For use 11, 2 is reasonable for both hiking and dispersed camping, 1 is reasonable for one of the two, 0 is reasonable for neither.

,

0 - Use is not reasonable
1 - Use is reasonable
* - For use ii, 2 is reasonable for both hiking and dispersed camping, 1 is reasonable for one of the
two, 0 is reasonable for neither.

| Attribute | Mnemonic | Units | Definition and Measurement Method |
|-----------|----------|----------------|---|
| Bl | FSREST | Fifths | Fifths of area in which firewood
cutting is restricted |
| B2 | FSFEE | Fifths | Fifths of area in which a fee is
charged for firewood cutting |
| ВЗ | FSFREE | Fifths | Fifths of area in which firewood cutting is free |
| B4 | PASTCUTS | Percent | Percent of area which has
apparently been logged |
| Β5 | MAINRTE | - | Location on main through route.
Areas that contain the main
through route were either marked
(1) for the road from Wayan to
the narrows or (2) for the road
from the south end of study area
to the narrows, or (7) on the
narrows road, including the con-
fluence of roads 1 and 2. Other
areas were marked either 3 (low
land), 4(canyon), 5 (ridges),
or 6 (other upland types). Low
land includes Mountain Valley
Bottom types (land types 01-06).
Canyons included canyonland types
(land types 18-21). Ridges in-
cluded both Ridgeland (land types
(07-09) and escarpments (land type
38-39). Other upland types, in-
cluded higher elevation areas or
steeper sloped areas such as in
side slopes (land types 24-35)
and mountain slopes 36 and 37,
and unstable scarp dip at upland
(14-17). |
| В6 | SODADIST | Miles | For land units with roads, the
distance in miles from highest quality
road in the unit to Soda Springs. |
| B7 | DEERVIEW | # Deer | Sitings of deer from Idaho Dept. of
Fish and Game aerial survey. |
| B8 | ELKVIEW | # Elk | Sitings of elk from Idaho Dept. of
Fish and Game aerial survey. |
| в9 | MOOSVIEW | # Moose | Sitings of moose from Idaho Dept. of
Fish and Game aerial survey. |

Table 18. Definition of additional indicators for estimating use intensity (Equation 5).

| Table | 18. | Continued. |
|-------|-----|--------------|
| TUDIC | 10. | oone inaca i |

. 1914:07**8**8 2¹⁰

•

| Attribute | Mnemonic | Units | Definition and Measurement Method |
|-----------|----------|----------------|---|
| B10 | ANGDAYS | Angler
Days | Allocated angler days from Idaho Dept
of Fish and Game survey and fishing
disaggregation formula. |
| B11 | TRAILMI | Miles | Miles of mapped trails in land unit. |
| B12 | ESTHVAL | - | Aesthetic quality of site, a
function of visual variety,
using DCPU Aesthetic Values map:
l = distinctive, 2 = common, 3 =
minimal. |
| B13 | LANDEXP | - | Land unit exposure, in degrees on
a circle of 2 miles radius
from unit centroid from which
the (barren) centroid can be
seen. The centroid was judged
not visible if it failed the
"rule of 1/4's:" 1) subtract
centroid elevation from radius
elevation and divided by 4, 2)
subdivide radius into fourths,
3) if the elevation difference
between the radius and any 1/4
radius exceeds |
| | | | $\frac{e_{cent} - e_{rad}}{4}$ |
| B14 | LANDOM | | then it fails the rule (view is
obstructed).
Land unit dominance, in miles of
gravel road from which unit
centroid is visible. Centroid |
| B15 | LANDVIEW | | is not visible if a) the road
is tree-lined, or b) if the
vector from the road to unit
centroid fails the rule of 1/4's
Landscape view, in degrees within
a circle of 2 miles radius
where elevations of 8,000 ft
or more are visible from the |
| B16 | FISHCOVR | | unit centroid.
Protective cover for fish.
Fraction of length with over-
hanging vegetation or snags.
(Summer site visit.) |

•

~35.

| Attribute | Mnemonic | Units | Definition and Measurement Method |
|-----------|----------|---------|---|
| B17 | SUBSTRT | | Predominant substrate. 4 =
cobble, 3 = gravel, 2 = sand,
l = silt. Mixed size is coded
with .5. |
| B18 | SILTED | | Degree to which siltation is apparent
heavy siltation=3, medium siltation=
2, light or negligible=1 (0=no third
order stream). |
| B19 | POOL | Percent | Percent of third order and higher stream reach in pools |
| B20 | RUN | Percent | Percent of third order and higher
stream reach in run (relatively
smooth, medium velocity surface
flow). |
| B21 | RIFFLE | Percent | Percent of third order and higher
stream reach in ripple (ripples and
relatively high velocity broken
flow). |
| B22 | SPRTFISH | | Volume of water sufficient to support
adult fish (l=sufficient, O=not
sufficient. |
| B23 | WILLOW | Percent | Percent of streambank length for
third order or higher streams
in riparian willow |
| B24 | AUMS | | Cattle animal unit months of available feed |
| B25 | SEPTIC | | Access to safe drinking water,
soil suitable for septic tank.
0 = neither, l = borderline
on at least one, 2 = both ok
(see A2) |

| Attribute | Characteristic Measured and Measurement Method |
|-----------|---|
| C1 · | General profitability of lumbering, price of lumber of the sort produced in the watershed. |
| C2 | Distance from sawmill (Afton, Wyoming; Montpelier, Soda
Springs and Pocatello, Idaho). |
| C3 | Total local lumber available. |
| C4 | Local economic impact of logging as determined by an economic multiplier. |
| C5 | Need of region for economic stimulation (current unemployment rate). |
| C6 | Size of local lumber industry. Percentage of county employ-
ment in wood products industry. |
| C7 | Population pressure demand for recreation activity as estimated by a gravity model ($\Sigma P/dn$). |
| C8 | General profitability of firewood cutting. Price of
firewood per cord: \$60.00 unsplit and delivered, \$80.00
split and delivered. |
| C9 | Price of competing fuels. Price per BTu of predominate
fuel type in area. City of Soda Springs (electric):
\$1.18 x 10 ⁻³ /Btu. Utah Power and Light (electric):
\$0.73 x 10 ⁻³ /Btu. Intermountain Fuel (gas): \$5.4 x 10 ⁻⁴ /Btu. |
| C10 | Priority of national goal to use domestic energy sources.
Percentage of fuel needs being imported. |
| C11 | General profitability of phosphate. Sale price of product phosphate and any associated by-products. |
| C12 | General cost of phosphate processing including pollution control at the plant. |
| C13 | General cost of phosphate mining including cost of restoring mined areas to meet environmental standards. |
| C14 | Local economic impact of phosphate mining as determined by an economic multiplier. |

1. Commercial logging

Estimates of the amount of timber harvested in 1980 were based on records of past timber sales and plans for future sales as obtained from the Forest Service. Over the past eight years, the harvest has averaged about 2,500 MBF. For grouping harvests according to sales, commercial logging was taken as a 0-1 variable according to whether a harvest was sequenced next in the Forest Service 5-year plan. Two sites were evaluated as possibilities for being next. One was the timber that would be harvested with the opening of the Diamond Creek mine. The other was the Smoky Canyon sale area as shown on the Forest Service timber harvest planning map. For these two areas, the harvest by land unit was calculated (but not used in the optimization model except for firewood as described below) as follows:

a. The sale area was estimated from the Forest Service map digitizer.

b. By assuming uniform distribution of the timber over a sale area, the total timber volume was divided by the area to give MBF per acre.

c. The portion of each land unit (Figure 6) in the sale area was estimated (in tenths).

d. The portion was multiplied by the land unit area and the average MBF/acre to estimate the harvest from the land unit.

2. Firewood cutting

Firewood cutting was allocated according to the amount of material present, physical access, and legal access. An index combining these indicators was used as follows to allocate cutting among study area units:

a. Material present. The availability of wood for the cutting was estimated from three variables: vegetative cover, beetle kill, and commercial logging. From assumptions on representative tree size, stand density, and percentage of dead trees, the estimates of material availability were

74.31 cords/conifer acre x 5% dead = 3.72 c/CA

57.29 cords/aspen acre x 10% dead = 5.73 c/AA

74.31 cords/beetle kill acre

1.0 cord/MBF commercial harvest

b. Physical access was represented by an index constructed to first increase and then decrease as the density of roads increased.

$$P_{a} = \frac{RDMI/SQMI}{4} - \left(\frac{RDMI/SQMI}{8}\right)^{2} \qquad (8)$$

c. Legal access to firewood was designated by a binary variable taken as 0 on private property, active mines, and areas where vehicle use is restricted.

d. Combining these three factors, the unit use index is $I_{2,i} = ([((UNITSIZE * % CONIF) - (UNITSIZE * % BEETKILL)/100)$ * CORD/CONIFACRE + (UNITSIZE * % BEETKILL/100* CORD/BEETACRE) + (UNITSIZE * % ASP/100 * CORD/ASPACRE)] $* (100 - % RESTRICT/100) * <math>\left[\frac{RDMI/SQMI}{4} - \left(\frac{RDMI/SQMI}{8}\right)^2\right]$ + (SALEBDFT/1,000 * UNITSIZE IN/SALESIZE) . . . (9)

The total firewood cutting was allocated proportional to this index.

3. Phosphate mining

Mine lease areas, acres disturbed, and pit boundaries were taken from the phosphate EIS and the Greiner Inc. impact study for the six operating or scheduled mines wholly or partially in the study area. The projected ore extraction over the mine life was divided by the pit size for average tons/pit acre. This was multiplied by the acres of pit in a unit to estimate tons per/unit as illustrated for the Diamond Creek Mine in Table 25.

4. Oil and gas exploration

The two exploratory holes drilled in 1980 were in land units 292 and 337.

5. Cattle grazing

The distribution of cattle grazing within areas where cattle are allowed to graze was assumed to be proportional to range productivity estimated in dry weight of annual forage production from information in Table 3. The division of the study area between cattle and sheep allotments is shown on Figure 7. Annual dry weights per unit area were taken as 2,500 for VH, 1,500 for H, 750 for M, 375 for L, and 150 for VL. First, potential productivity was estimated as P_i , the annual production potential of unit i in pounds per acre. Each P_i was calculated by multiplying the above dry weight by the area of the unit and dividing the dry weight of one AUM. The maximum grazing allocation (all animals) for a unit was taken as 0.6 P_i based on an assumption that no more than 60 percent of the dry weight of forage produced should be consumed to maintain healthy range conditions.

The Forest Service data on cattle grazing provided total AUMs for large "allotments" only partly within the boundaries of the Upper Blackfoot study area. Allotment AUMs were assigned to the study area

| TONS/UNI | MINE
ACRES | LAND
UNITS | AVE RAGE
TONS/ACRE | PIT SIZE |
|------------|---------------|---------------|-----------------------|----------|
| 3.45 x 10 | 24 | 101 | 143,750 | 400 ac |
| 0.29 x 10 | 2 | 117 | | |
| 10.06 x 10 | 70 | 119 | | |
| 5.17 x 10 | 36 | 120 | | |
| 3.73 x 10 | 26 | 125 | | |
| 22.86 x 10 | 159 | 126 | | |
| 3.31 x 10 | 23 | 152 | | |
| 8.34 x 10 | 58 | 153 | , | |

Table 25. Estimated phosphate production from the Diamond Creek Mine.

proportional to the fraction of the allotment area within the study area based on the assumption that average range conditions prevail over large areas. AUMs were assigned to land units within the study area proportional to land unit range productivity (the product of P_i and area).

6. Sheep grazing

Sheep grazing was distributed over the land units by the method described above for cattle with the same estimates of range productivity but different designated allotment areas.

7. Deer winter feeding

The index originally proposed for allocating big game grazing among land units had of the form:

where

- $I_{k,i}$ = grazing by species k in unit i
- P_i = AUM production potential of unit i
- L_i = average elevation of unit i

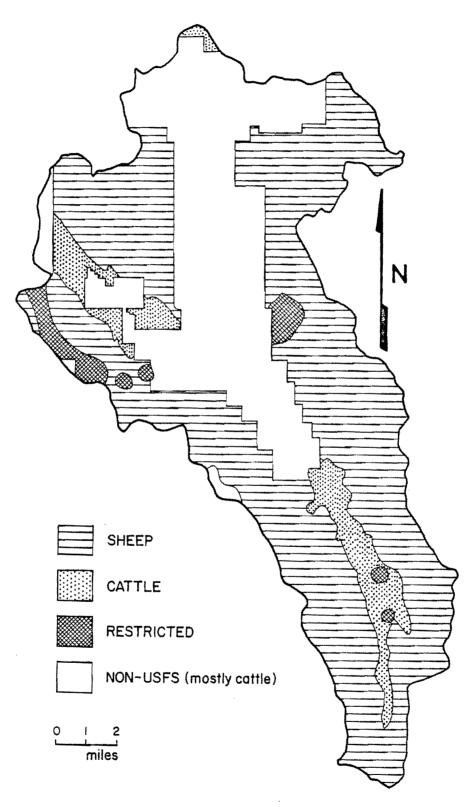

Figure 7. Cattle and sheep grazing allotments in the Upper Blackfoot watershed.

where

wk,j = weighted preference of species k importance for vegetation type j

t_{i,i} = fraction of unit i in vegetation type j

Data on the locations of big game sitings (Table 10) were analyzed in an attempt to estimate b_1 , b_2 , and b_3 . The information proved insufficient to be conclusive, but vegetation preference appeared to be the dominant factor. Consequently, b_1 and b_2 were taken as zero, and b_3 was taken as unity.

The vegetation weightings estimated from the siting data were as shown on Table 26.

The species grazing preference index was used to allocate range forage residual to cattle and sheep use. The residual amounts could also be checked for sufficiency in supporting current game populations. Deer grazing totals from the Wildlife Survey were distributed over the land units proportional to the values computed for $I_{k,i}$ from Equation 10.

8. Elk winter feeding

Elk feeding was distributed among land units using the coefficients shown in Table 26 to compute the $I_{k,i}$. Elk are shown to feed relatively more on grass and less on brush than do deer.

9. Moose habitat

Moose feeding was also distributed among land units by the same procedure. Moose were generally found among the trees and may feed largely on willow.

10. Hunting

The Forest Service estimated hunting for 1980 for the northern portion of the study area (890 hunter days in units 205 through 343), the southern portion east of Diamond Creek (2000 hunter days), and the southern portion west of Diamond Creek (1020 hunter days). These hunter days were disaggregated to land units proportional to a weighting index, based on unit size, use restrictions, maximum elevation, and unit type, and having the form:

$$I_{10,i} = \frac{(\text{unit mi}^2)(\% \text{ not restricted})[(-16,000 (max. elv.) - 0.1 + (type)]}{\text{base area}}$$

(12)

The rationale for the functional form combined the concepts:

a. Size - the larger the unit, the more hunting.

b. Restriction - the fewer the restrictions, the more hunting.

c. Elevation - the higher the elevation, the less the hunting.

| Vegetation | Species | | | |
|------------|---------|-------|-------|--|
| Туре | Deer | Elk | Moose | |
| CONF | 0.278 | 0.335 | 0.629 | |
| ASPEN | 0.181 | 0.278 | 0.223 | |
| MBRUSH | 0.357 | 0.102 | 0.063 | |
| SAJGR | 0.062 | 0.054 | 0.007 | |
| RIPGR | 0.000 | 0.147 | 0.000 | |
| WILLOW | 0.122 | 0.084 | 0.077 | |

Table 26. Species preferences of vegetation types.

d. Land types - some land types are better hunting areas than others due to better accessibility and habitat. Land types (defined on Table 3) were weighted from these considerations as follows:

| Number | Weight | |
|-------------------|--------|--|
| 1-3, 18-21, 38-40 | 0.0 | |
| 14-17, 36-37 | 0.3 | |
| 10-13, 22, 23 | 0.5 | |
| 7-9, 25-35 | 1.0 | |

11. Hiking - dispersed camping

Hiking in a unit was estimated as proportional to a use index calculated from road type, aesthetic attractiveness, restrictions, stream presence, vegetation, elevation, and ownership:

I_{11.i} = Total DC&H days

* (SQMI/160) * AESTHETICS * RESTRICT * ROADTYPE *

STREAMPRES * AV ELEV. * VEG * OWNERSHIP . . (14)

where

SQMI/160 = proportion of study area in unit

- AESTHETICS = 1.0, 0.5, or 0.05 if the highest Forest Service aesthetic class is 1 (distinctive), 2 (average), or 3 (minimal), respectively
- RESTRICT = fraction of area restricted to hiking
- ROAD TYPE = 0.01 if road type is paved or none and there are no trails
 - = 0.11 if road type is paved or none and there are trails

- = 0.75 if road type is gravel and there are no trails
- = 0.85 if road type is gravel and there are trails
- = 0.90 if road type is graded dirt and there are
 no trails
- = 1.0 if road type is graded dirt and there are trails.
- = 0.5 if road type is four wheel drive dirt and there are no trails
- = 0.6 if road type is four wheel drive dirt and there are trails
- STREAMPRES = 1.0 if a third or higher order stream is present, and 0.5 otherwise

AV ELEV. = 1.0 if the unit average equals the study area average (7,475 feet) and declines toward 0.25 as the unit average diverges from the area average

- VEGETATION = 0.9 if riparian grass is dominant
 - = 0.8 if aspen is dominant
 - = 0.5 if conifer is dominant
 - = 0.1 if sage and grass are dominant
 - = 0.01 if mountain brush or willow is dominant

OWNERSHIP = proportion of unit publicly owned

12. Concentrated camping

The Forest Service reports campground use for the two developed sites. Estimates, however, are subject to significant error and probably on the high side.

13. Roads

Maps showing road locations were directly used to assign road lengths by types to land units.

14. Snowmobiling

The index hypothesized for allocating snowmobiling among land units judged the primary factors to be the presence of trails and roads, distance to the Narrows, aesthetic class, elevation, and restrictions. Specifically:

I14,i = Total snowmobile days * (1 - % restricted/100)
 * ROAD TYPE * ROAD DISTANCE * AESTHETIC VALUE
 * (Maximum elevation/100) (14)

Road type indicators were 1.0 for paved, 0.8 for gravel, 0.4 for dirt (passenger), 0.25 for dirt (four wheel drive), 0.2 for trail, and 0 for none. Road distance indicators ranged between 0 and 1.0, with minimum values assigned to units very close or very far from the Narrows. The aesthetic value indicator was taken as 1.0 for distinctive, 0.66 for common, and 0.33 for minimal. The elevation indicator suggests that snowmobilers prefer the better views from higher elevations other factors being equal.

15. Summer ORV

The index used to allocate ORV use was based on area, road type, use restrictions, aesthetic class, and elevation. Specifically,

I15,i = Total ORV days * (area/160) * ROAD TYPE (1 % restricted/100) * AESTHETIC CLASS * ELEVATION

(15)

Road type was assigned 0.0 for paved, 0.5 for gravel, 0.75 for dirt (passenger), 1.0 for dirt (four wheel drive), 1.0 for trail, and 0 for none. Aesthetic class was assigned 1.0 for distinctive, 0.75 for common, and 0.50 for minimal. Elevation was assigned a value between 1.0 and 0.75 based on a comparison of a unit's elevation with that of the study area as a whole. Units with average elevation less than or equal to the study area average of 7,475 were assigned 1.0. Units with a higher average elevation were assigned a number according to the formula

 $i = -0.00023 \ \bar{E} + 1.966.$ (16)

16. Buildings

The 12 counted buildings were directly assigned to the land units in which they were located.

17. Archeological or historical sites

Lane's Grave was identified with the land unit in which it is located, and a map showing the route of the Lander Cutoff was used to identify the land units crossed.

W1. Fish Habitat

The fish habitat quality index (Equation 7) was constructed from observed characteristics of a water unit (stream reach) and provided values that could be directly assigned to the land units through which the stream flows. Fish populations were assumed to be proportional to stream length for a given value of the habitat index.

W2. Fishing

The 1978 census estimates of fishing activity were subdivided into seven reaches (Table 11). Estimates of fishing intensity per unit stream length in each of the 55 reaches identified for analysis were based on information on a fishing intensity index constructed from information on fish population and factors affecting access to the streams including restrictions placed by property owners, distances from the nearest road, streamside vegetation, and flow. The angler days within the seven reaches defined for the census were allocated to the 55 water units in proportion to the ratio of the unit length to the reach length, weighted according to the fishing intensity index.

W3. Runoff

The distribution of average annual runoff among source land units was estimated by applying the Kentucky Watershed Model (Ross 1970). The model was initially calibrated for the 2.70-square mile Stewart Creek Catchment. The simulation used hourly precipitation amounts recorded at Henry, Idaho, and daily minimum and maximum temperatures recorded at Soda Springs. Hargreaves and Samani's (1982) method was used to estimate daily evaporation from the temperature data. The calibration was based on matching 25 flow measurements taken during the summer of 1976. In that year, the earliest measurement was 1.7 cfs on May 4. The flow peaked from snowmelt at 10.0 cfs on June 2 and receded through the summer to 1.5 cfs on September 23. No flow measurements were made during the winter.

For modeling purposes, the Stewart Creek Catchment was divided into two elevation zones, one averaging 1300 feet higher than the Henry gage and the other 2300 feet higher. Model parameters were adjusted by trial and error until the simulations matched the available recorded flows. Of the model parameters, the snowmelt degree-day factor had the primary influence on the timing and magnitude of the runoff peak, and the soil depth and permeability had the primary influence on the annual runoff volume. The 25 recorded flows and corresponding synthesized flows for the accepted calibration, listed in Table 27, had a correlation coefficient (r^2) of 0.902.

The land cover changes in the Upper Blackfoot likely to most significantly affect runoff are timber cutting that removes the conifers, grazing of cut areas afterwards, and mining. For each cover situation, a set of hypothetical model parameter values shown in Table 28 was used to simulate the runoff volumes, flood peaks, and low flows shown in Table 29. Assumptions used in hypothesizing values for the model parameters were 1) interception is approximately equally divided between the conifer forest and understory growth, 2) mining disturbs the earth to the point of doubling the available volume of depression storage, 3) grazing reduces depression storage to two thirds to three fourths of its former value, 4) mining breaks up underlying impervious layers and triples active soil moisture storage, 5) transpiration rates are reduced to 70 percent of their former value by cutting timber, 50 percent by grazing, and 10 percent by mining, 6) mining loosens the soil and increases infiltration rates by a factor of four thirds, and 7) grazing reduces infiltration rates by half (Hawkins and Gifford 1979).

The hydrologic effects of mining, lumbering, and grazing vary with precipitation rates and elevation (principally because shorter seasons reduce total evapotranspiration). The relationship was investigated by

| Date | Recorded Flow | Simulated Flow |

Table 29. Analysis of runoff variation with elevation and cover.

-----5

Ala

.

simulating ranges of average annual precipitation amounts in the Blackfoot from 17.25 to 32.00 inches, and elevations from 300 to 2500 feet higher than the Soda Springs temperature gage. Precipitation is correlated with elevation, but other factors such as aspect and exposure also have a large influence. Consequently, different precipitation amounts were hypothesized for given elevations.

Three elevations and four precipitation totals (Table 29, L1-L9) were used to simulate total annual runoff, the highest flow peak (snowmelt runoff), and the runoff volume during the driest summer month. Combinations with high precipitation at low elevation and low precipitation at high elevation were excluded. A regression of the simulated annual runoff on precipitation in inches (P) and elevation in feet (E) estimated the annual runoff volume from a conifer forest in inches (R') to be

$$R' = -10.10 + 0.000832 E + 0.640 P \qquad (17)$$

with a correlation coefficient (r^2) of 0.998. A regression of the simulated annual flow peak (cubic feet per second) on the same two variables gave

$$Q' = -13.36 + 0.000829 E + 0.803 P$$
 (18)

with $r^2 = 0.982$. For low flows (monthly runoff in second foot days), the relationship was

$$L' = -88.45 + 0.00524 E + 4.352 P \qquad (19)$$

with $r^2 = 0.996$.

The above results show all three relationships to be highly linear. Consequently, rather than simulate all nine points for land cover changes, only the two extreme points were simulated, and the linear relationships found for conifer forest were assumed to represent the pattern of variation for the intermediate situations. The consequent procedure for estimating R, Q, and L for watersheds with other cover characteristics was to multiply the above equation by constants.

For a catchment with the trees removed (M on Table 29), it was thus assumed that runoff can be estimated as a simple multiple of the runoff from the conifer forest:

$$\mathbf{R} = \mathbf{F}_{\mathbf{R}} \mathbf{R}' \qquad \dots \qquad (20)$$

where, based on points L1, L9, M1, and M9,

For catchment cover that combines conifer forest and other vegetation, with C defined as the decimal fraction of the catchment with conifer cover,

Because a value for R' can be interpolated for any precipitation and elevation from Table 29, this equation provides an unverified but reasonable basis for estimating runoff from all possible combinations of annual precipitation, elevation, and cover.

For snowmelt flood peaks, the terminology used was

where

$$F_0 = -0.0651 \ 0' + 3.223$$
 (24)

Also,

$$Q_{\rm m} = (F_{\rm O} + C - C F_{\rm O}) Q'$$
 (26)

The same three equations were also used for low flows with

 $F_L = -0.0064 L' + 1.595$

From these equations, one can estimate the hydrologic effect of cutting conifer forest from a portion of the watershed. For example, by applying Equation 22 (or the corresponding equations for Q and L) with C_1 as the conifer fraction before cutting and C_2 as the fraction afterwards, R_{m_2} may be obtained by placing C_2 in Equation 22, and R_{m_1} by placing C_1 . The increase in annual runoff is

$$\Delta R = R_{m_2} - R_{m_1}$$
 (27)

For estimating the effects of mining a catchment presently covered with conifer, the assumed relationship was

where

 $M_{R} = -0.0088 R' + 1.337 \dots (29)$ If the catchment has some other cover before mining, $R = M_{R} R'/F_{R} \qquad (30)$

For mixed conifer cover,

$$R = C M_{R} R' + (1 - C) M_{R} R'/F_{R} \qquad (31)$$

For flood peaks and low flows, the relationships to be used in place of Equation 29 are

| $M_Q = -0.0137 Q' + 1.775$ | • | • | • | • | • | • | • | (32) |
|---|---|---|---|---|---|---|---|------|
| $M_{\rm T} = -0.0039 {\rm L}^{\prime} + 1.549$ | | | • | • | • | | • | (33) |

For estimating the effects of grazing (assuming grazing does not pertain to conifer forests),

$$R = G_R F_R R' \qquad (34)$$

where

if the grazing intensity consumes all available AUM. For a lesser grazing intensity

 $G_i = G_a/G_m$ (36)

where G_a AUM out of G_m total are actually consumed. The annual runoff volume from an area grazed at intensity Gi was estimated as

For flood peaks and low flows, the relationships to be used in place of Equation 35 are

$$G_Q = 0.0150 Q' + 1.188 \dots (38)$$

Multipliers from these relationships are summarized in Table 30.

W4. Water Quality

The water quality in a given stream reach represents an integration of upstream effects, pollutant loadings and dilution occurring within the reach itself, and biogeochemical transformations occurring within the reach. Although the water quality data base for the study area was much better than that existing in most wildland watersheds, Doebley and Messer (1981) found the following problems with interpreting the effects of tributary land use on water guality:

1. Annual variability in stream discharge influenced water quality at least as much as land use.

2. Variations in water quality could not be adequately described by mixing and dilution processes.

3. Chemical variability among closely spaced sites along a stream reach, resulting from ungaged groundwater inputs and stream ecosystem biogeochemistry, makes all but the most highly controlled studies of land use effects within-reach water quality highly suspect.

The result was that extensive statistical analyses gave few high correlations between land use and water quality parameters in any of the downstream reaches.

An additional problem was encountered in defining water quality. A nutrient that could contribute to good water quality for fish habitat or irrigation water could be detrimental to offsite use in a reservoir. Alternatively, parameters such as suspended solids may be detrimental to

Table 30. Hydrologic multipliers with land use change.

both fish habitat and reservoir siltation, but the order of magnitude of the corresponding impacts could be significantly different. Mahmood and Messer (1982) attempted to circumvent this problem by creating a singlevalued multivariate statistical water quality index for the study streams. In this index, the criterion for decreasing water quality was the difference between a group of weighted water quality variables in a specific stream reach (normalized according to their standard deviations) and the mean values for all reaches in the study area. The index appeared to be a good predictor of invertebrate biomass in a stream reach, and an example of how the index could be used in a linear programming model was given. However, insufficient data were available to calibrate the model for the study area. Consequently W4 was judged to be too complex for further detailed simulation in this study.

Tabulation of Use by Land Unit

The disaggregated use data are given in the 20 (W4, water quality excluded) by 343 matrix of Table 31. As is obvious from the above descriptive material on the methods of estimation, many gross approximations were made. Table 31, however, does provide a general notion as to the pattern of spatial variability of use over the total area.

Table 31. Estimated 1980 uses by land unit.

CHAPTER 5

INTERACTIONS AMONG USES

Introduction

The primary political motivation for land use planning has been to reduce adverse external effects from land uses by property owners. Harm inflicted on neighbors generated a rationale for protecting the overall public interest through oversight preventing undesirable and unnecessary adverse impacts of market-based land use patterns on society and the environment. In pursuit of this lofty goal, planning practice has not yet gone much beyond making qualitative judgments on compatibility. Tools permitting quantitative tradeoffs are needed. Optimal resolution of the conflicts among uses requires quantitative estimation of the 1) benefits from land use (assumed largely convertible to economic units), 2) public values to be protected (assumed largely environmental in the Upper Blackfoot area), and 3) interactions among uses. All three types of estimates are incorporated in the modeling described in the next chapter. An initial exploration of the types of interaction occurring among uses of high mountain areas, a simplified approach to their quantification, and a series of applications follow here.

Interaction Classification

Interactions among land uses can be classified according to whether they are within or between uses, within or among land units, size scale of relevant units, simultaneous or time lagged, additive or multiplicative, complementary or competitive, or associated with a technical (including environmental) or social causative linkage. By way of illustration, interactions occur among different uses on the same land unit (a herd of cattle drinking while people are fishing), among the same use on different land units (both cattlemen and fishermen being more likely to use a good unit if it is not isolated from other good areas), or among different uses on different units (hiking attractiveness being affected by mining on the opposite hillside). They may be caused by simultaneous use or be associated with time lags (effects on hiking continuing after mining operations cease). Interactions may have a greater impact than the additive effects of individual uses (recreation visitation being increased by complementary activities by amounts that exceed direct proportionality to those other uses). The land units on which interactions are analyzed may be small homogeneous areas, such as those shown on Figure 6, areas as large as the entire Upper Blackfoot region covered by this study, or even larger. The causative relationships vary with land use size

(multiple interferences between cattle and fishing at many locations in a large area having a different impact than localized encounters). The interactions may be either positive (the imparting use encourages more absorbing use) or negative (discourages). The causative relationship may be either technical (physical effect of vegetative change on the quantity and quality of runoff) or social (pecuniary or psychological factors affecting desire to visit high mountain areas).

The relative importance of an interaction varies with the physical and ecological context of a region, with the social and cultural background of the people who visit it, with the regional economy and its national role, and with the uses occurring and their relative magnitudes. For long run improvement of land use planning methodology, research is needed to develop better understanding of all the interactions among land uses and how they vary spatially in different contexts and time frames. Simple judgments on compatibility need to be replaced with quantitative information on kinds and degrees of interaction.

As a beginning in this direction, the exploratory effort of this study concentrated on interactions among different simultaneous uses on the same small unit for two reasons. These direct interactions are simpler to identify and easier to incorporate in regional modeling and thus the logical starting point for building toward a better understanding of the total interactive framework among land uses.

Also, most current uses of the Upper Blackfoot study area are at relatively low intensities, and thus the interactions explored in this study are at relatively low levels of the two principal uses within a context of low levels for all the other uses as well. Effects that are additive at low intensities tend to become interactive at higher intensities, and thus interactions are expected to be greater and causally more complicated in more intensely used areas. For example, we can expect population and technological growth to increase popular expectations on the quality of mountain environments.

Identification of Simultaneous, Local Interactions

The identification of local interactions among different uses simultaneously occurring on common land units in the Upper Blackfoot study area was done by systematic expert evaluation of each element in the matrix of Figure 8. Each use is considered as having the potential for both imparting and absorbing impacts. The matrix elements represent specific pairs of imparting and absorbing uses to be analyzed for a significant interactive relationship. The diagonal represents interactions among users engaged in the same activity (the effect one grazing cow has on another's available forage) as handled by the relationships for estimating use intensity (Equation 3).

A number of factors have to be considered in estimating the magnitude of an interaction among uses. The magnitude may be governed primarily by the intensity of the imparting use. It may also be

influenced by local land attributes (impact of off road vehicle use on fish habitats varying with soil erodibility). An element may contain more than one interactive process (commercial timber cutting may improve firewood cutting by leaving slash piles and harm firewood cutting by removing trees). Interactive processes may be quite different at one combination of intensities of the imparting and absorbing uses than they are at another combination or in one context of intensities of other uses than they are in another context.

Figure 8 classifies the major relationship types as:

- Tl: The imparting use physically (directly or through some ecological interrelationship) prevents or makes the absorbing use less profitable or otherwise less desirable.
- T2: The imparting use induces an increase in the amount of the absorbing use through such varied mechanisms as firewood cutters who also fish, roads required to serve commercial logging operations, or camping at sites with a good view of feeding elk or moose.
- T3: The imparting use hampers by congestion or causes security problems for people involved in the absorbing use. Clark et al. (1971) have found motivations for vandalism to include entertainment, convenience, disregard, ignorance, and interference with personal goals.
- T4: The use changes runoff volumes or water quality and thereby impacts other users of that water.
- D: One or more of the above relationships is important but specific attributes of the land unit need to be measured to forecast the magnitude of the effect. Relationships of this sort are presented in Table 32, and attributes for those relationships not previously defined in Tables 12 or 18 are defined in Table 33.

Often, it is assumed that activities (say A_1 and A_2) are competitive over the full range of their production as shown in Figure 9a. However, in many cases, both complementary and supplementary relationships exist between activities at a given site. In Figure 9a, A_1 and A_2 are shown to be competitive over the full range of their production in that an increase in A_2 from n to m requires giving up ba of A_1 or vice versa. The more general situation is depicted in Figure 9b in which increasing A_2 from 0 to n results in a complementary increase of ab in A_1 at n level of A_2 . Increasing A_2 from n to p does not affect A_1 , and the two activities become supplemental. Further increasing A_2 reduces A_1 and the two have become competitive.

The diagramming of a specific interactive relationship requires analysis of the processes governing physical interactions and the collection of information on how people perceive social interaction situations. The relationship may be affected by indexable site

factors and the intensities of other uses. In general, one could conceive a multidimensional interactive diagram with one axis for each use, but development of the concept is not practical.

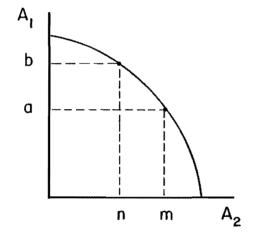

Analysis of Major Interactions

In this study, exploration of the interactions was based on experience, expectation, and qualitative observation. The model presented in Chapter 6 provides a basis for identifying sensitive interactions for further study.

For a first pass, for model development, Figure 10 identifies a reduced set of the interactions on Figure 8 deserving examination in the context of the Upper Blackfoot study area by direction and type of causal linkage. These interactions are numbered on Figure 11 and discussed by number below.

1. <u>Phosphate Mining on Other Commercial Use</u>. Opening a phosphate mine requires cutting all the commercial timber in the area (PT) but then eliminates commercial timber operations thereafter (NT). After mining, an area could potentially return to commercial timber production. For modeling, phosphate mining was assumed to require immediate harvest of all commercial timber and prevent harvest thereafter. The effect of mining on firewood cutting is much the same except that it was assumed that it would be impractical to strip the firewood remaining after a timber harvest before mining and thus only the second (NT) effect was considered. Cattle and sheep grazing would also be excluded while mining is underway.

2. <u>Grazing on Runoff</u>. The hydrologic modeling was used to estimate the effects of grazing on runoff volumes, peaks, and low flows given an annual precipitation and grazing intensity. The results are in Equations 34 through 39.

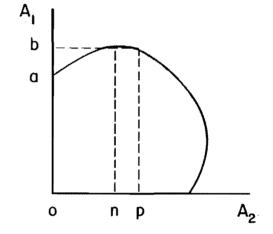

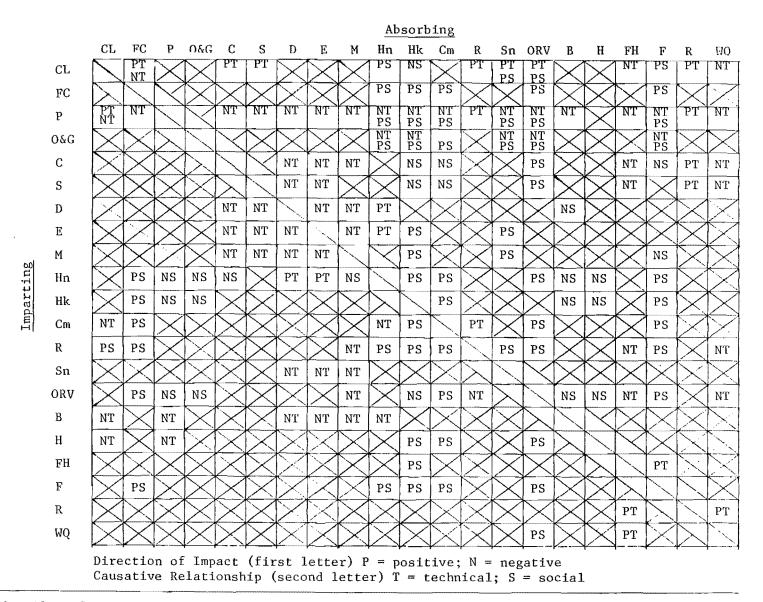

Figure 9b. Production possibilities curve for activities with complementary, supplementary, and competitive relationships.

i.

.

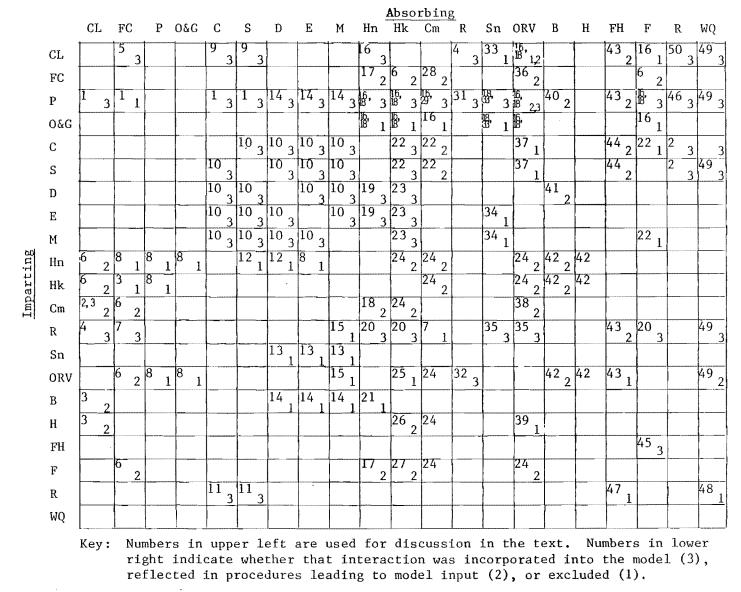

Figure 11. Numbering of specific interactive relationships.

119

3. Permanent Developments on Commercial Lumber. Campgrounds, buildings, and historical sites generally preclude commercial timber harvest from the immediate area, largely because of the greater desirability of saving trees for their aesthetic value. A reasonable protected area needs to be designated for each site.

4. <u>Roads on Commercial Lumber</u>. Roads are required to service commercial lumber operations, and the cost of providing necessary access must be considered in deciding whether or not to open a new area for logging. Road cost depends on topography, soil conditions, and distance of new construction required. After the timber is cut, the road may either be left open (affecting a number of other uses) or closed (causing some additional cost). For this study, specific road costs were estimated for specific situations.

5. <u>Commercial Lumber on Firewood Cutting</u>. Commercial timber harvest leaves slash that can be used for firewood. The amount depends on the relative amounts of trees profitable for lumber and smaller trees and brush in the area and on the timber cutting method. For this study, 0.5 cord of firewood per 1000 board feed of lumber was assumed.

6. <u>Recreation on Firewood Cutting</u>. People who visit an area for hunting, hiking, camping, ORV touring, or fishing are more likely to cut firewood than people who would otherwise stay home; they are already in the area. Recreationists need to be questioned to derive a relationship.

7. <u>Roads on Firewood Cutting</u>. Road access is required to haul cut firewood away, but people vary in the type of vehicle that they own and willingness to drive on rough roads. The interaction should ideally be approached through a relationship defining the effect of poorer road quality in reducing cutting, but this study used a simple judgment as to whether or not the access was sufficient for firewood cutting to occur.

8. <u>Recreationists on Commercial Activity</u>. Hunting, hiking, and offroad vehicle use may interfere with mining, oil and gas exploration, and cattle ranching by attracting people who commit acts of vandalism or who advocate land use management practices that restrict commercial activity. The extent of these problems can be probed by questionnaire.

9. <u>Timber Cutting on Grazing</u>. Cutting out the trees increases the growth of forage for cattle and sheep with clear cutting having a greater positive effect than does more scattered removal of the conifers (Miller and Krueger 1976). For quantities, one can estimate the number of board feet removed from an acre of ground and how many AUMs would then be produced from the grass that would start to grow on the area.

10. <u>Competition among Animals for Food</u>. Cattle, sheep, deer, elk, and moose theoretically compete for food as they graze an area of land. Overall, cattle, elk, and moose require about the same amount of food with that amount being about 5 times the amount required by deer or sheep. The competition, however, is limited by the fact that various animals differ in food preferences (food compatibility index by Stoddard, Smith, and Box 1975) and in thoroughness with which they remove plants when feeding. Miller and Krueger (1976) found no direct competition for forage between big game and cattle as long as the cattle were not overusing the range. The summation of the food consumed thus only provides a starting point for estimating the total animal populations the vegetation an area can support, and a more detailed analysis would need to account for season, condition of the range, and type of vegetation.

11. Water Quality on Camping and Fish Habitat. Water quality deterioration can harm fish habitat and make streamside locations less pleasant for campsites. Aesthetics and drinking water safety can both be affected. The water samples taken in the Blackfoot area do not show pollutant concentrations that would cause problems in the study area. The primary problem is the nutrient loading of downstream reservoirs.

12. <u>Hunting on Deer and Elk</u>. Obviously, hunters remove the game they kill from the animal population grazing on the watershed, and this reduces the AUMs of food consumed. Removal rates can be estimated from statistics on the number of animals killed per hunter day. Since both the hunters and the animals wander over large areas, adjacent units will also be affected.

13. <u>Snowmobiling on Deer, Elk, or Moose</u>. Snowmobiling has been known to cause deer to move out of sight of the vehicles (Bury et al. 1976). Elk appear somewhat more sensitive. However, these interactions were considered minimal because of low levels of activity and the fact that much of the browsing is at night. Petrie's (1971) survey in Canada suggests that the situation may actually be more upsetting to conservationists than to the animals. Lindsay (1974) found the greatest conflict imparted by snowmobilers to be on homeowners. In Upper Valley the issue would be whether harm was found when people reoccupied their buildings in the spring.

14. Land Closure on Deer, Elk, or Moose. Mining and building remove areas from forage production for native animals. The effect is probably smaller than it is on cattle and sheep because the effect of the physical removal of foodstuffs is likely less than that of institutional restrictions against grazing. Buildings are so few in the Upper Blackfoot area that any effect would be quite minimal. Mining temporarily destroys large areas of forage, and the AUMs removed from production provide a good estimate of this interaction.

15. <u>Roads on Moose</u>. Road construction also removes a certain amount of land from forage production, but these quantities are small for narrow dirt roads passing through forested areas. Moose were identified for consideration as a possible additional problem because the primary moose habitat is in willow areas along the larger streams also followed by the roads. Large amounts of traffic could potentially disturb the moose or the habitat, but this did not turn out to be a problem in the study area.

16. Commercial Activity Increasing Hunting. Jobs bring people into an area where many of them will hunt. The quantitative effect can be estimated from information on the number of employees per commercial unit, the number of hunters per employee family, and the average hunter days such people spend in the area.

17. Firewood Cutting on Hunting and Fishing. People who come into the area to cut firewood may also hunt or fish during the trip. Data on firewood cutting during deer season, however, did not indicate that significant numbers of people were combining these recreation purposes.

18. Commercial Activity Decreasing Recreation Activities. Commercial mining operations act to prevent hunting or hiking near the mine sites and create an environment where hiking and dispersed camping are less attractive anyway. Hunting is restricted in the immediate vicinity of campgrounds for safety reasons and because of game being scared away by concentrations of people. Mine operators were questioned as to experiences with trespassers into restricted areas, and this did not seem to be a significant problem.

19. Deer and Elk on Hunting. The presence of more game animals would logically make an area more attractive to hunters. Good deer and elk habitat could attract hunters, probably to a lesser extent, even though the animal populations were not high. Since hunters spread out over many land units, this interaction aggregates over larger areas than many. Questionnaires can provide data on preferences and areas of hunting activity, and these could be correlated with data on habitat quality.

20. <u>Roads on Hunting and Fishing</u>. Road access is a significant factor influencing hunting and fishing locations. If information on the locations of hunting and fishing is available, correlation techniques can be used to determine the significant factors and estimate the relative influence of roads. Poor roads may also make good trails that facilitate hiking. Much of the dispersed camping in the area requires road access for bringing vehicles or equipment into the area.

21. <u>Buildings on Hunting</u>. Regularly occupied buildings would discourage hunting in the vicinity, and cabins may facilitate hunting activity. Both relationships were determined to be insignificant in the Upper Blackfoot study area.

22. <u>Cattle and Sheep on Camping and Fishing</u>. Cattle and sheep disrupt camping, and cattle drinking in numbers disrupts fishing. Moose may have a similar effect. Large animals would be kept out of dedicated campgrounds and would quickly encourage dispersed campers to move elsewhere. As an approach for quantifying the relationship, one might examine the relationship between dispersed camping in user days and the feed value of vegetation in an area in AUMs. If the feed is primarily grazed by cattle and sheep, one would expect a negative slope to the line, suggesting less camping the more an area resembles a cow pasture.

23. <u>Game Animals on Dispersed Camping</u>. The correlation between user days and AUMs mentioned under 22 would be expected to be more positiv where game animals were the primary grazers. Elk herds are not exp sted to cause campers to leave to the degree cattle would.

24. <u>Hunting, Dispersed Camping, and Offroad Vehicles</u>. Many people to enter an area for recreational purposes can be expected to engage to more than one activity during the day and then stay overnight e ther at one of the dedicated campgrounds or dispersed among other sites. People who come in family units or other groups may split d fing their recreation day with various members selecting differe t activities. They may use offroad vehicles to get about. In order t quantify these interactions, hunters need to be asked whether they st π overnight in the area and, if so, whether in a dedicated campgro id or elsewhere and whether they use an offroad vehicle. Hikers is dispersed campers need to be asked whether they are overnightin (perhaps after a vacancy opens) at a campground or driving an offroad vehicle. People staying at campgrounds can be asked about hiking. Overall, analysis of this interaction requires collection of data on multiple activities by recreation visitors.

25. Offroad Vehicles on D Camping. Offroad vehicle use generat i noise that awakens side to and is generally disturbing to people siting remote areas to get away from congestion. This specific conflict is just one manifestation of a more general one between people visiting an area in search of solitude and other people desirin "higher technology" activities requiring vehicles, chain saws, g is, etc (Bury et al. 1976).

26. <u>Historical Sites on Hiking</u>. Some people may come through the are purposefully following the Old Oregon Trail or to visit Lane's ave or some other specific site. A questionnaire would be require to quantify the extent of this effect.

27. Dispersed Camping on Fishing. A scenic and comfortable site affords pecial relaxation where people seek to camp and fish together. These c plementarities are among recreationists seeking trimative experie e whereas those under 24 are among "higher teacher" in activities and those under 25 are conflicts of the two. A three kinds of interactions need to be probed by asking recreat mists about the experience they are seeking and their reaction to people engaged in other activities. Crowding becomes another factor a more densely used areas, but it is not currently a factor in the Upp Blackfoot Basin.

28. Firewood Cutting on Camping. People who cut firewood may also st vovernight in a campground and burn wood in the process. In derivin a relationship between firewood cutting and the size (number of camp tes) of a facility like a campground, one needs to convert capacit to a use rate where the capacity greatly exceeds the use rate, a it does for the other uses in the Upper Blackfoot study area. Capacit is not a constraining factor and use equals demand. For larger mands capacity limits use during peak periods, and a capacityuse rel ionship needs to be derived (James and Lee 1971, pp. 405-7).

29. <u>Phosphate Mining on Campgrounds</u>. Close and visible presence of an o rating or, to a lesser extent, a closed mine area detracts from ca ground attractiveness. In an area with few campgrounds and many possible sites, the reasonable policy is to avoid locating campgrounds in areas where the mines are visible.

31. <u>Phosphate Mining on Roads</u>. Phosphate mines require access roads for bringing miners and equipment into the area and for taking the ore out. New roads have to be constructed or improved for much heavier traffic than would otherwise be necessary as new mines are opened.

32. Offroad Vehicles on Roads. The steep dirt roads of the study area rut quickly, particularly when wet, with vehicular traffic. Where the vehicles leave the road, tire marks add to erosion, runoff, and sedimentation problems. A relationship expressing the annual cost of maintaining roads in acceptable condition as a function of vehicular traffic and such other independent variables as slope and soil characteristics would be part of expressing this interaction. Regulations could prohibit offroad vehicles from areas where they would lead to undue erosion and where the erosion would cause significant harm to downstream fish habitat. A comprehensive analysis would recognize that regulation is never completely successful and that enforcement costs need to be weighed against benefits.

33. <u>Commercial Activities on Snowmobiling</u>. The commercial activities close down during the severe Idaho winters, but some people enter the area to snowmobile. The effect is analogous to that of commercial activity on hunting (number 16) but different because the recreation is outside the time for seasonal jobs in the watershed and thus associated instead with employment induced indirectly in nearby towns.

34. <u>Elk and Moose on Snowmobiling</u>. Some snowmobilers may seek out elk and moose wintering in the lower meadows and adjacent areas of willow brush as part of their recreation experience. The effect could be quantified by questioning snowmobilers or perhaps observing the effects of the presence of the animals on snowmobile track patterns.

35. Roads on Snowmobiles or Offroad Vehicles. Whether in winter or summer, roads are the main locations for vehicular activity. Both summer ORVs and winter snowmobile traffic can be examined for the fraction of the activity occurring on roads. The roads are probably more of a factor in directing locations for vehicular activity than they are in increasing total usage of the area. Potential policies on road use should be framed in this light.

36. Firewood Cutting on Offroad Vehicles. Offroad vehicles permit a firewood cutter to haul his wood out of more remote areas, and hence attractive firewood sources in remote areas may induce ORVs into the area. A survey would need to examine the extent to which ORVs are being used for this purpose.

37. Offroad Vehicle Use by Ranchers. People watching over cattle and sheep operations often use vehicles for access into remote areas (bringing salt, finding animals, etc.). Ranching operations could be analyzed to estimate the amount of offroad vehicle traffic generated per AUN of grazing in the area. 38. <u>Camping on Offroad Vehicles</u>. Campgrounds can become the center of activity for people going into more remote areas during the day by means of offroad vehicles. A survey of the types of vehicles driven by campers would be a starting point for estimating the extent of this activity.

39. <u>Historical Sites on Offroad Vehicles</u>. People following the Old Oregon Trail (either exactly or approximately) or visiting some other site of historical significance may go on foot, by horseback, or by two or four-wheeled vehicle. In this case, the traffic was light and not judged to be worth the trouble of more detailed analysis.

40. Phosphate Mining on Buildings. Buildings are required near an operating phosphate mine for caretaking and service functions. Workers are induced to live closer to the site. Because of the lack of winter access to Upper Valley, the permanent residential and commercial support activities are outside the study area, and temporary summer trailers were counted with dispersed camping.

41. <u>Deer on Buildings</u>. Deer can be quite destructive to landscaping during winter periods with deep snow when available browsing runs short; however, in the study area, the buildings were closed for the winter and generally not landscaped.

42. <u>Technology Recreation on Buildings</u>. The presence of hunters, hikers, and offroad vehicles is often associated with an increased incidence of unpleasant confrontations and vandalism. For this interaction, one might estimate adverse impacts as a linear multiple of recreation use, with the coefficient possibly varying with the type or intensity level of use.

43. Erosion on Fish Habitat. Activity that disturbs the ground surface, including lumbering, mining, road construction, and the rutting of roads by vehicular traffic, add to soil erosion by amounts varying with soil erodability and climate. Muddy water is harmful to most fish species, and the sediments left deposited in the stream can ruin the habitat for a long time afterwards.

44. <u>Cattle and Sheep on Fish Habitat</u>. If not enclosed, livestock drink from the stream, often walking down into the water and causing the banks to slough. This activity gradually changes the shape of the stream channel and also contributes to turbidity and siltation of fish habitat downstream. Hydraulic and ecologic observations at livestock watering areas are needed to quantify this interaction.

45. <u>Fish Habitat on Fishing</u>. Good fish habitat attracts fish, and fish attract fishing activity, other factors being equal. Of the other factors, access is probably the most important, with a good habitat near a road being fished much more than is an equally good one at a more remote location.

46. <u>Mining on Runoff</u>. The relationships summarized in Table 30 were used to estimate the effects of mining on runoff.

47. <u>Runoff on Fish Habitat</u>. The volume and time pattern of runoff has important effects on fish habitat with larger streams able to support a greater variety of species. The variation in land use expected in the Blackfoot catchment, however, is not expected to cause large enough variations (much smaller than natural fluctuations from year to year) in runoff to make a significant change in habitat except in a few localized areas immediately downstream from mines or temporarily after timber cutting (Mahmood and Messer 1982).

48. <u>Runoff on Water Quality</u>. Most erosion and pollutant loading is associated with major storm events. Most of the effect of land use on both runoff quantity and quality is associated with disturbances to vegetative cover or the land surface. Gaged data on several small catchments in the study area were analyzed statistically for relationships between runoff and water quality (Doebley and Messer 1981).

49. Erosion on Water Quality. Most of the phosphorus, nitrogen, and other nutrients and pollutants washed into a stream are associated with soil disturbances that expose material once deeper underground to be leached by surface runoff. Data on disturbances and water quality need to be examined for this purpose.

50. <u>Clearing on Runoff</u>. The analysis based on varying parameters within the Stanford Watershed Model according to how they are altered by clearing showed average runoff increases with clearing ranging from 32 percent at higher elevations with wetter climates to 58 percent in lower and drier areas (Table 29). One would also expect greater percentage increases in dry than during wet years.

The Data Problem

A number of researchers have explored the sociological determinants of outdoor or forest recreation. Nielsen and Catton (1971) developed an information retrieval system for compiling relevant literature. Hendee and Harris (1970) explored recreationist attitudes and believed users to be less willing to respond to management measures to control behavior than they actually were probably because the manager contacts are biased toward more negative individuals. Walter and Schofield (1977) presented the central task of wilderness recreation resource management as reconciling diverse objectives, and Pendse and Wyckoff (1974) probed techniques for tradeoffs among environmental goods. The state of the art is still groping for practical methodology, but all agree that specific analysis requires specific local data.

The questionnaire of Appendix A was prepared to explore the interactions among visitors participating in firewood cutting, hunting, hiking and dispersed camping, concentrated camping, snowmobiling, offroad vehicle use, and fishing. The questions sought information on the attributes influencing locations chosen for recreation, amounts of recreation use, feelings of people in the community about the desirability of various watershed uses (for estimating M_{ui} in Equation 34), and perceived complementaries and competitions among uses. Actual recreationists in the Upper Blackfoot study area proved too few to collect a meaningful sample. As an alternative approach, known recreationists were identified in the towns, but the study area proved to provide such a small part of their total recreation experience that targeting their responses to relationships in the study area was questionable. In the end, this attempt at data gathering was abandoned; but the interviewing scheme outlined in Appendix A provides a foundation for future efforts.

Conclusion

Interactions are key to land use planning. The analysis of the kinds of interactions that occur and the wide variety of linkages between impacting and absorbing uses presented in this chapter, however, proved that, even in the relatively less interactive high mountain watershed context, a great deal of research is needed to quantify these relationships and achieve planning objectivity. In fact the many topics suggested in the pages of this chapter are so many and varied that the obvious immediate need is for prioritization. Such a basis is sought in the next chapter through a model to quantify how optimal land use patterns vary with interaction magnitudes.

•

CHAPTER 6

APPLICATION OF OPTIMIZATION MODEL

Introduction

Optimization modeling is an inherently iterative process. Since comprehensive optimization would encompass the universe, a realistic modeler must select some primary values and relationships, incorporate them into his model, evaluate the results, and modify the model as necessary to have relationships applied in range, add important factors previously omitted, and otherwise achieve results that match those experienced in real situations.

The scope covered by a given model should be determined by what is important in the real world being modeled, the current understanding of real world relationships, and the issues of interest to those applying the model. The universe may theoretically be approached through one large model or a number of smaller models. A model of more limited scope facilitates probing specific issues in greater depth.

For the Upper Blackfoot study area, one could conceive of separate models for evaluating groups of related uses. Separation makes sense for uses that are not particularly interactive with others (e.g., oil and gas exploration with snowmobiling) but is absurd for such decisions as allocating pasture to cattle without considering the needs of sheep. One could also conceive of a model covering all the uses but taking the area as a whole as just one land unit. Separation of land units and the separation of uses are both ultimately based on judgments of minimizing the importance (from the viewpoint of the model application at hand) of the interactions between them.

Several other considerations are also important in defining the internal land unit size and the overall geographical scope of a model:

1. Smaller internal land unit sizes require greater locational specificity in the data, and this is only acquired at a cost. Data acquisition cost should be compared with the benefit gained from better analysis of local interactions.

2. Smaller land units are easier to characterize in that they have specific identifiable properties and do not have to be represented by averages that try to represent widely heterogeneous situations. 3. Many uses need to be permitted somewhere in a larger area but need not be included in every smaller area. One needs to cover a larger area to ensure that such necessary uses are provided somewhere.

4. Forest Service land managers think in terms of land use over larger areas than do property owners.

Model Overview

One useful tool is the generation of a range of Pareto optimum alternatives for consideration in the planning process (Bishop et al. 1976). Generating these alternatives becomes geometrically more difficult with increases in the complexity of the physical system or the number of competing objectives under consideration. Various mathematical programming techniques have been successful, and linear programming has proved to be particularly useful (Zelany 1974). It was therefore decided to generate noninferior land management alternatives through application of a mixed-integer linear programming (LP) model.

The purpose of the LP model is to determine the optimal mix of uses and locations within the study area. The optimization is done with regard to some objective function, such as maximization of the net present worth of the uses, subject to constraints on the availability of resources and the all-or-nothing character of such decisions as opening mines, building roads, or expanding campgrounds. The general form of the model is

subject to:

Ax ≶ b

and

 $I_{j} = 0, 1$ j = 1, ..., 5

The application in this study optimizes over the total Blackfoot study area among the uses determined to be sufficiently interactive and important for analysis and considers both economic (primarily of the user) and environmental (primarily of the public) objectives.

Inclusion of Uses in the Optimization Model

Table 7 lists 17 land and 4 water uses for analysis. In preparing a model to determine the optimal mix of uses for the Upper Blackfoot watershed, four of the land uses were judged as better set exogeneously to the model or as consequences of other choices in the model. Specifically:

4. Oil and gas exploration is based on evaluations of geologic conditions that are outside the scope of the model, and the current level of exploration in the watershed has relatively small interactions with other uses or environmental impacts.

13. Existing road capacity is generally sufficient to serve the needs for access to the area, and new needs are tied to specific expansion of other uses (new phosphate mines for example) and are best evaluated along with those uses.

16. Buildings are not a significant use in the area.

17. No archaeological resources were identified, and the only significant historical resources were associated with the Old Oregon Trail. This isolated segment of a long trail is a relatively minor historical attraction, and analysis of its development for tourism did not seem worth the effort.

W4. No effort was made to associate either economic value or energy consumption (the surrogate used to index environmental impact) with the water quality indices, and thus this use was not explicitly brought into the optimization.

Objective Function

For the remote high mountain setting of the Upper Blackfoot River watershed, the primary values associated with use of the area were judged to be economic and environmental. Economic values were measured in monetary units. After considerable deliberation, it was decided to measure environmental impact in units of energy expended in using an area based on the hypothesis that the degree of environmental disruption is roughly proportional to the amount of energy spent in logging, mining, livestock management, recreation, etc. In the objective function, monetary benefits were to be maximized, and environmental impacts were to be minimized. Hence, the objective function (expanded from Equation 4) has the form:

where the E_u represent marginal adverse environmental impacts and the function is summed over the m uses considered on n units. Economic multipliers (M_{ui} in Equation 4) were not brought into the analysis, and V_u and E_u were assumed to be constants over all units. Estimation of the two sets of objective function coefficients (V_u and E_u) is described below.

Economic Coefficients

The uses were classified into the categories of commercial products, animal feed, recreation, and water. Separate methods were used to estimate the coefficients for the four categories.

1. The commercial products are lumber and phosphate ore. Based on current market prices for products of the quality produced in the Upper Blackfoot watershed, the value of 1000 board feet of lumber was estimated at \$50, and the value of a ton of phosphate ore was estimated at \$25.

2. The monetary value of cattle and sheep grazing was estimated from the equivalent feed value of hay to be \$5 per AUM. Deer, elk, and moose were judged to have different grazing habits than do livestock and thus to remove \$4 worth of livestock feed per AUM utilized.

3. The economic values of recreation activities (firewood cutting, hunting, hiking dispersed camping, concentrated camping, snowmobiling, ORVs, and fishing) were estimated by constructing a demand curve based on visitation-distance relationships derived from estimates of the number of visitors by activity in an average year and the distribution of population living within 90 miles (James and Lee 1971, Chapter 16). By using travel cost to develop a demand curve, the economic value of a recreation day is estimated as

where C, n, and D are defined by the three following equations. C is the cost per mile of travel to the site in dollars per visitor day spent there and estimated by summing the various cost components with the relationship:

where 2.42 is an average ratio of round trip road distance to one-way air distance

m is the variable vehicle operation cost in dollars per mile

- t and v estimate the value of time spent in travel by dividing the value of a vehicle hour of travel time in dollars by the mean vehicle velocity in miles per hour
- b and p account for the number of visitor days spent at the site per round trip by automobile with b being the average number of days those traveling together remain at the site and p being the average number of passengers per vehicle.

In Equation 42, n is the exponent in the gravity model used to estimate visitation

$$V = KP/D^n \qquad . \qquad . \qquad . \qquad . \qquad . \qquad . \qquad (44)$$

where K and n are estimated by regression based on data from many communities on the number of visitors (V) of a total population (P) traveling (D) miles to the site. A larger value of n from the regression implies that a larger share of the visitors are coming from nearby. Finally, D is the average travel distance to the site estimated as:

over m communities of origin.

From an analysis of a map of the area within 90 miles of the study area, 1970 census data, and data collected by Idaho on the home locations of people coming into the area for various recreation activities (Table 34), values of D were calculated from Equation 45 and n from Equation 44. The calculations of U_V are based on Equation 43 and shown in Table 35. The values of m are based on a marginal vehicle operating cost of 15 cents per mile for autos and 17.25 cents for trucks. Percentages coming by truck or pickup were estimated as 95 for hunting, 90 for snowmobiling or ORVs, 85 for firewood cutting, camping or fishing, and 80 for hiking.

4. The economic value of water as it flows through the Colombia River system to the Pacific was estimated at about \$5.00 per acre foot by Hastay et al. (1971). Escalation to 1980 prices gives a value of \$17.30. Most of the above value is from hydroelectric power generation and thus only minimally affected by water quality.

Environmental Coefficients

Energy expended by man in his activities on a land area disrupt the environment. The environmental coefficients were taken as the fuel consumption per unit of use and were assumed not to apply to natural uses (big game feeding, fish habitat, and water yield). Petroleum fuel is by far the largest energy source used by activities in the area, and petroleum consumption can be estimated more readily than the total work involved and partially supplied by a multitude of lesser energy sources. Details on the estimation of petroleum consumptions by use are in Appendix B, and the results are listed in Table 36. Table 34. Travel distance relationships for various recreation activities.

Population and Visitation Distribution

| Range (miles) | 0-30 | 30-60 | 60-90 |
|-----------------------------------|-------|--------|-------|
| P | 21000 | 205000 | 14400 |

Aggregated Land Planning Units

The 343 land planning units proved too many for optimization with the data refinement available for this project, and aggregation into larger areas was necessary. In evaluating the differences that need to be preserved in distinguishing among aggregated land units, the two land characteristics judged to be most important were habitat quality for big game and erosion potential. Other major differences were preserved by distinguishing among the three major drainage divisions of the study area.

The aggregation procedure followed was:

1. Habitat preference indexes were calculated for deer, elk, and moose on each land unit. Preference indices are a function of vegetation, with coefficients based on animal observation data from the Idaho Department of Fish and Game. The index values were then divided into low, middle, and high ranges.

2. Erosion potential for each unit was assigned in accord with Forest Service land type classifications (Table 3) to low, medium, or high.

3. The study area was divided into three major watersheds: a) Diamond Creek, b) Lanes Creek except its Sheep Creek tributary, and .c) Blackfoot River with Angus and Sheep Creeks.

4. Land units within each of these three larger areas were grouped by erosion potential and animal preference as shown in Table 37. The 18 aggregated land planning units are shown on Figure 12.

Model Constraint Equations

The modeling to optimize land use over the Upper Blackfoot study area followed the basic linear programming format of Equation 41. The objective functions were optimized subject to constraints growing out of the interaction matrix and described use-by-use below.

A typical constraint represents a limitation or capacity of a resource on a particular use on a specific land unit. For example, the grazing constraint in land unit 3 can be expressed as:

 $CAT_3 + 25.8 I_{Ph} - 0.000325 LOG_3 + SHE_3 < 1288.8$. . . (46)

where

CAT₃ is the AUMs allocated to cattle

SHE3 is the AUMs allocated to sheep

| Diamond Creek
Number | Lanes Creek
Number | Blackfoot
Number | Definition |
|-------------------------|-----------------------|---------------------|---|
| 1 | 7 | 13 | Medium erosion potential
with no high habitat rating
for deer, elk or moose |
| 2 | 8 | 14 | Medium erosion potential
with a high habitat rating
for deer, elk, or moose |
| 3 | 9 | 15 | High erosion potential with
no high habitat rating for
deer, elk or moose |
| 4 | 10 | 16 | Low erosion potential with
a high habitat rating for
deer, elk, or moose |
| 5 | 11 | 17 | High erosion potential with
a high habitat rating for
deer, elk, or moose |
| 6 | 12 | 18 | Low erosion potential with
no high habitat rating for
deer, elk, or moose |

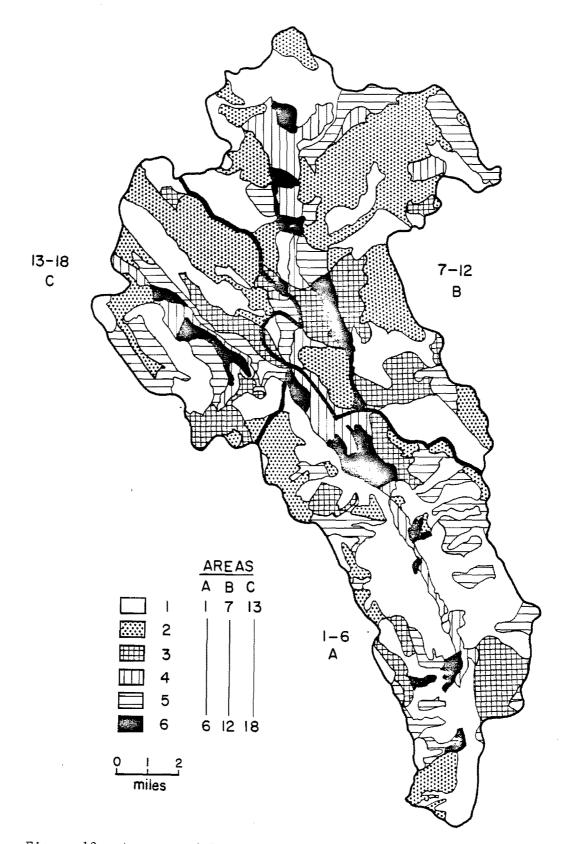

Table 37. Definition of aggregate land use units.

.

·

۰.

•

 I_{Ph} is a binary variable designating construction ($I_{Ph} = 1$) or non-construction ($I_{Ph} = 0$) of the new phosphate mine

LOG3 is the amount of commercial logging in the land unit.

The right hand side value of 1288.8 is an estimate of the present number of AUMs available for cattle and sheep in unit 3.

The coefficients translate competing or complementary uses into effects on grazing AUMs. For example, construction of a new phosphate mine will cause a loss of 25.8 AUMs while commercial logging will lead to a gain of 0.000325 AUMs per board foot of timber cut.

Other constraints reflect competitive or complementary uses on a land unit. An example is between timber production and firewood availability. Typically, timber harvesting leaves waste wood material, called slash, that has no value as commercial timber but which makes suitable firewood. Therefore, when timber is harvested, the firewood supply will be increased by an amount related to the quantity of timber produced. For example,

where

FIRE5 is the number of cords of firewood removed in land unit 5

LOG₅ is the number of board feet of timber extracted from land unit 5

The coefficient of LOG₅ states that each 1000 board-feet of timber produces 1 cord of slash suitable for firewood. Specific equations by purpose are discussed below.

1. Commercial logging

Logging occurs in sale areas designated by the Forest Service either as part of their overall harvesting plan or as part of clearing the land before mining. One constraint equation is introduced for each sale. For timber sales:

RLOG_k: LOG_k - LOG_{kmax} ICL_k + $\Sigma \Sigma P_{im} PR_m \leq 0$. . . (48) i m For phosphate mine settlement sales: RCLPH_{gk}: LOGPH_{gkmax} IPH_g - LOG_k ≤ 0 (49) i = index on land units

l = index on new phosphate mines

- k = index on timber sales
- m = index on projects to mitigate logging impacts

 LOG_k = amount of timber to be harvested, kth sale

 $LOG_{k_{max}}$ = maximum potential harvest, kth sale

 $I_{CL_k} = 0$, 1 for kth sale

- Pim = maximum board feet lost due to mitigation projects, land unit i
- PR_m = fraction of mth project utilized

 $I_{PH_0} = 1$, 0 for lth new mine

In applying these equations, the timber sale (LOG_k) sites (land units covered) and amounts (of timber to be harvested) must be decided and specified in advance. The Forest Service timber harvest plan was obtained and used for this purpose. The maximum potential harvest $(LOG_{kmax} \text{ or } LOGPH_{2k})$ is based on the timber productivity potential (Table 3) and current cutting practices. Restrictions against cutting around campgrounds, buildings, and historical sites would have to be deducted. The model does not cover the gradual recovery of the forest for another harvest because of the emphasis here on short term analysis. Where needed, one can incorporate time by calculating expected changes in variables over a given period and entering these as data for successive model runs.

2. Firewood cutting

Firewood cutting in a unit is assumed to be constrained by available wood, and the total amount of firewood cut in the study area is assumed to be constrained by demand.

RFIRE_j: FIRE_j \leq F_jp + b_{jk}LOG_k + Σ d_{jm} IR_m - Σ C_j IPH₂ . . (50) RFCUT_j: Σ FIRE_j \leq FIRE_d - r_jPERM_j (51)

j = index on aggregated firewood units

k = index on logging sales

- ℓ = index on new phosphate mines
- m = index on new road networks
- $FIRE_{i}$ = amount of firewood available in ith unit
 - F_{jp} = amount of presently accessible firewood in ith unit
 - ^bjk = amount of firewood added on ith unit from kth logging sale (typically 1.0 cord per 1000 bd ft)
 - $C_{j\ell}$ = amount of firewood lost from restrictions around new phosphate mine ℓ
 - d_{im} = amount of firewood gained from mth road network
- FIREd = firewood demand projection, based on population and heating costs
- PERM_j = firewood cutting permit cost in ith unit x cords under permit

 r_i = firewood not taken per dollar permit cost in ith unit

 LOG_k = timber harvested, kth sale

Secondary demands for firewood associated with visitors who are coming primarily for other recreation uses were not estimated because they would be small compared with the primary demand which was taken as a function of the population in the surrounding area and the cost of alternate energy sources. Survey data on complementarities among uses would be required to quantify any secondary demands. Information on road density may provide a useful index for estimating, rj, the amount of firewood not taken.

3. Grazing - cattle, sheep, deer, elk, moose

The modeling of feeding by livestock and big game on the range was done in two parts. The first equation estimates the total food available for livestock from the range productivity potential (Table 3) on lands not restricted from grazing by mining, food eaten by big game, plus additional range production achieved by logging and range augmentation projects. The second equation limits total consumption by the five animal groups to the food produced. Other limitations are that livestock cannot eat more than 60 percent of the available food and that the food allotted to big game in the total study area has to be enough to supply their needs.

AUM: AUM =
$$\sum_{j} A_{pj} + \sum_{jk} g_{jk} G_k - \sum_{jk} a_j I_{PH_{\ell}} - \sum_{j} DW_j - \sum_{jk} W_j$$

- $\sum MW_j + \sum \sum h_{jk} LOG_k$ (52)

| GRj: | $CAT_j + SHE_j - A_{pj} - \sum_{j} g_{jk} G_k + \sum_{\ell} a_{j\ell} I_{PH_{\ell}} + DW_j + i_{j\ell}$ | | | | | | | | | |
|--|--|--|--|--|--|--|--|--|--|--|
| | $EW_j + MW_j - \sum_k h_{jk} LOG_k \leq 0$ | | | | | | | | | |
| | $(CAT_j + SHE_j \leq .6 \text{ AUM})$ | | | | | | | | | |
| DW: | $\sum_{j}^{\Sigma DW} j \ge D \qquad (54)$ | | | | | | | | | |
| EW: | $\sum_{j}^{\Sigma EW} j \ge E \qquad \cdots \qquad \cdots \qquad \cdots \qquad \cdots \qquad \cdots \qquad (55)$ | | | | | | | | | |
| MW: | $\sum_{j}^{\Sigma} MW_{j} \ge M \qquad . \qquad$ | | | | | | | | | |
| j | = index on aggregated unit | | | | | | | | | |
| k | = index on grazing enhancement/control projects | | | | | | | | | |
| l | = index on new phosphate mines | | | | | | | | | |
| AUM | = total AUM production | | | | | | | | | |
| <pre>Apj = present AUM production, jth aggregated unit (from
productivity potential)</pre> | | | | | | | | | | |
| ^g jk | <pre>= increment in AUMs realized from kth enhancement, jth unit</pre> | | | | | | | | | |
| G_k | = fraction of kth enhancement project actually undertaken | | | | | | | | | |
| ajl | = AUMs lost in jth unit if ℓ th new phosphate mine becomes active | | | | | | | | | |
| I _{PH} | = integer variable on lth new phosphate mine | | | | | | | | | |
| DWj | = AUMs allotted to deer, jth unit | | | | | | | | | |
| EWj | = AUMs allotted to elk, jth unit | | | | | | | | | |
| MWj | = AUMs allotted to moose, jth unit | | | | | | | | | |
| logk | = amount of timber harvested, kth sale | | | | | | | | | |
| ^h jk | = AUMs added from kth timber sale (AUM/bd ft) | | | | | | | | | |
| CATj | = AUMs reserved for cattle, jth unit } up to 60% AUM | | | | | | | | | |
| $^{\rm SHE}$ j | = AUMs reserved for sheep, jth unit | | | | | | | | | |
| D | = total deer AUMs | | | | | | | | | |

E = total elk AUMS

M = total moose AUMs

In these equations, all AUMs are in cattle units; and suitable conversions must be made for other species. The present AUM production is estimated from median of productivity potential range for land unit type. Forest Service documents suggest that 85-90 percent of study area is producing at range potential. AUMs added when cut timber is replaced by range are estimated in AUM/bd ft and expressed in h_{jk} . It was assumed that all range productivity would be lost from areas around phosphate mines even though technically game could still utilize undisturbed areas restricted to cattle and sheep. Big game are allocated AUMs according to the preference indices for the unit. Unused potential can be used to increase either domestic or game use. The preference indices assume that the plant composition in a cow AUM is the same as that for other animals.

4. Hunting

The hunting equations match supply and demand. The supply is determined by available game and hunting sites. The demand is allocated regionally and increased by new mining or logging employment opportunities in the area.

| (supply) HUSUP _j : HUS _j - Σ e _{jm} I _{Rm} - b _j DW _j - c _j EW _j + Σ f _j I _{PH} - $\frac{1}{m}$ |
|--|
| $\Sigma a_{jk} LOG_k \leq HU_{jmax} \dots (57)$ |
| (demand) HUDEM _j : HUS _j \geq HU _j |
| $\begin{array}{cccc} \text{HUDEM}_{\texttt{tot}} \colon & \Sigma \ \ \text{HU}_{\texttt{j}} \geq \text{HU}_{\texttt{reg.dem}} & + \Sigma \ \ \text{Vj}_{\texttt{l}} \ \ \ \text{IPH}_{\texttt{l}} + \Sigma \ \ \text{ujk} \ \ \text{LOG}_{\texttt{k}} \\ & \text{j} & \text{j} & \text{j} \\ & & \end{array} $ (59) |
| J J J (59) |
| j = index aggregated land unit |
| m = index on road network |
| <pre>& = index on new phosphate mines</pre> |
| k = index on timber sale |
| HUS _j = defining variable |
| a_{jk} = change in hunting supply from kth timber sale |
| ^b j = hunting opportunity from deer habitat |
| c _j = hunting opportunity from elk habitat |

e_{jm} = net change in hunting in jth unit due to access from mth road network

 f_{10} = change in hunting opportunity from ℓ th new mine

u_{ik} = change in hunting demand from kth timber sale

 V_{iq} = change in hunting demand due to *l*th new mine.

 $DW_{i} = AUMs$ for deer, jth unit

 $EW_i = AUMs$ for elk, jth unit

HU jmax = maximum hunting, jth unit

 I_{PH_0} = binary variable for *l*th new mine

 I_{Rm} = binary variable for mth road network

HU_{reg.dem.} = regional demand for hunting

Hunting demand was assumed to be primarily determined by population, and secondary demand associated with other recreational uses was not estimated. Hunters are assumed to hunt only where allowed.

5. Hiking - dispersed camping

The same supply and demand approach was used in modeling hiking and dispersed camping. The supply equation tries to capture factors encouraging or discouraging hikers coming to a given area. The demand equation adds hiking by miners entering the area to an allocated demand.

(supply) HISUPj: HISj - $\sum h_{jk} - \sum f_{jn} I_{Rn} - g_j$ (cEWj + dMWj + eDWj) + bjm IPHm + CATj + SHEj \leq HIjmax . . (60) (demand) HIDEM: HISj \geq HIj (61) $\sum HIj \geq$ HIreg.dem. + $\sum V_{jm}I_{PHm}$. . . (62) j = index on aggregated units g_j = hikers attracted by prospect of big game sitings k = index on hiking improvement projects m = index on new phosphate mines n = index on nth road network

143

HIS₁ = defining variable

$$\begin{split} h_{jk} &= \text{change in hiking in unit j from kth hiking project} \\ H_k &= \text{fraction of kth hiking project undertaken} \\ f_{jn} &= \text{change in hiking in unit due to nth road network} \\ I_{R_n} &= \text{binary variable on nth road network} \\ EW_j &= \text{elk AUMs in j} \\ MW_j &= \text{moose AUMS in j} \\ DW_j &= \text{deer AUMs in j} \\ b_{jm} &= \text{hiking lost in j due to mth phosphate mine} \\ I_{PH_m} &= \text{binary variable on mth phosphate mine} \\ CAT_j &= \text{cattle AUMs in j} \\ SHE_j &= \text{sheep AUMs in j} \\ HI_{jmax} &= \text{maximum present hiking/dispersed camping in jth unit} \\ HI_j &= \text{hiking demand in j} \end{split}$$

HLreg.dem. = hiking demand in study area

 V_{jm} = hiking/dispersed camping demand induced by new mine m

Any extra use of the Oregon Trail due to its historical significance must be included in base indicators (HI_j) . The disturbances from cattle and sheep; CAT_j and SHE_j, need coefficients (RVD/AUM) as do the attractions from big game, EW + DW + MW. Noise has an unknown relationship in this framework. Induced demands or mixed motive users are not distinguished.

6. Concentrated camping

The supply and demand relationships used for concentrated camping tried to estimate the demand to expand the facilities from an allocated regional demand and campground use by miners.

(supply) $CCSUP_j$: $CMPS_j - CMPexp_j \leq CMP_j$ (63)

 $\Sigma CMP_{j} \ge CMP_{reg.dem.} + \Sigma V_{\ell} I_{PH_{\ell}} . . .$ (65)

j = actual campground

CMPS₁ = defining variable

CMP_{expj} = expansion in campground capacity required to satisfy demand

CMP; = present camping utilization

CMP jpresent = present camping availability

CMP_{reg.dem.} = demand for camping in study area

 V_{o} = increase in camping

I_{PH} = binary variable on new phosphate mine

While the Forest Service is not considering providing a new campground, the supply equation permits the supply to increase and identifies the point when demand becomes sufficient to warrant a new campground. Camping demand from firewood cutters is calculated in CMP_{reg.dem.}. Cattle and sheep are excluded from developed camp-grounds. Any new campground is assumed to require road access.

7. Roads

The equations for roads compare current traffic capacity with that needed to service users and indicate an improvement project when needed.

 ROD_{j} : IPh - IR₁ - IR₃ ≤ 0 (new road provided for new

phosphate mine)

 I_{R_0} = binary variable on *l*th road network

It is difficult to isolate the cost of roads required to provide for a timber sale, but the model does require road access to a sale site. Road construction is the responsibility of commercial operators. Even though other use of mine roads is generally restricted, they would be included in $I_{R\ell}$. However, the proposed new mine at Diamond Creek would use a county road. Major sedimentation problems can be associated with unimproved roads. One possible sediment

145

control project would be to close roads where erosion is a problem. Present restrictions on ORVs are factored into current use estimates. The model is not structured to add restrictions.

8. Snowmobiling

The same basic supply and demand structure is again used for snowmobiling.

| supply SSUP _j : SNOS _j - Σ SjkSNk - Σ tjnIRn + rj $_{\ell}$ IPH $_{\ell} \leq$ SNOjpres kej n |
|---|
| (68) |
| demand $SDEM_j$: $SNO_j \leq SNOS_j$ (69) |
| $\Sigma SNO_{j} \ge SNO_{reg.dem.} + \Sigma V_{\ell} I_{PH_{\ell}} \ldots \ldots (70)$ |
| j = index on aggregated units |
| k = index on kth snowmobiling project |
| <pre>l = index on lth new phosphate mine</pre> |
| n = index on nth road network |
| SNOS _j = defining variable |
| s_{jk} = snowmobiling in j provided by kth project |
| SN_k = fraction of kth project undertaken |
| t_{jn} = snowmobiling in j provided by nth road network |
| I_{Rn} = binary variable on nth road network |
| SNO _{jpres} = maximum present snowmobiling in j |
| SNO _{reg.dem.} = demand for snowmobiling in study area |
| V_{l} = snowmobiling demand from new phosphate mines |
| $I_{PH_{g}}$ = binary variable on new phosphate mine |
| r = snowmobiling lost from new mine |

Snowmobiling is mainly a function of the availability of roads, t_{jn}, especially roads with scenic loops. Increased demand is associated with miners coming into the area, and loggers and oil and gas explorers could be added if desired. Elk and moose viewing was assumed not to have a significant influence on use.

9. ORVs

The supply and demand equations for offroad vehicles were:

demand
$$ORDEM_j$$
: $ORV_j \leq ORVS_j$ (72)

$$\Sigma ORV_j \ge ORV_{reg.dem.} + \Sigma V_q PH_q$$
 . . (73)

q = index on phosphate mines

j = index on aggregated units

k = index on ORV opportunity from kth project

l = index on road networks

ORVS; = defining variable

ojk = increase in ORV opportunity in j from enhancement project k

 OR_k = fraction of ORV project undertaken

 r_{j_0} = change in ORV opportunity in j from road network ℓ

 I_{R_0} = binary variable on network ℓ

ORV_{pres} = current ORV opportunity

 $ORV_{i} = ORV$ demand in j

ORV_{reg.dem.} = ORV demand in study area

 V_{q} = ORV demand from new phosphate mines

 PH_q = binary variable on new phosphate mines

ORV users are assumed to avoid restricted areas. Avoidance of these is included in the supply estimates, and adjustments would have to be calculated for projects that change restricted areas. The ORV increase from firewood cutting and other recreation and commercial uses of the study area were assumed covered in the primary demand estimates. 10. Fishing

supply FISUP_j: FISS_j - Σ fjkFk - Σ rjmIRm -kej mej cjFHj ≤ FISjpres (74)demand FIDEM;: FIS; < FISS; (75) $\Sigma \text{ FIS}_{j} \geq \text{FIS}_{reg.dem.} + \Sigma V_{\ell} PH_{\ell} \dots \dots$ (76) i j = index on watershed unit k = index on fishing enhancement project m = index on road network ℓ = index on new phosphate mines. FISS; = defining variable f_{ik} = increase in fishing enhancement project built F_k = fraction of fishing enhancement project built r_{jm} = increase in fishing opportunity in j from road network m I_{Rm} = binary variable on road network m C_j = change in fishing opportunity in j from change in fish habitat $FH_i = fish habitat in j$ FIS_{jpres} = current fishing opportunity FIS_j = fishing in j FIS_{reg.dem} = fishing demand in study area V_q = change in fishing demand from new mine ℓ PH₀ = binary variable on new phosphate mines

Supply and demand for fishing were represented by the relationships.

148

11. Fish habitat The index used to represent the quality of fishing habitat was FHAB; = FHABpres - SED; - WQI; (77)where $FHAB_{pres} = (100 - \sqrt{(PRR - 45)^2}) \times SUBSTRATE \times SEDIMENT + COVER$ (78)SED; is Equation 35 WQI; = 48.78 + .019 (% logged x area) + .26 (AUM/stream mile) (79)j = index on watershed unit SED; = sedimentation index WQI; = Ramzi's water quality index PRR = pool-riffle ratio SUBSTRATE = predominant substrate SEDIMENT = present sedimentation level

COVER = percent of cover in reach

The impacts by other uses on fish habitat are expressed via SED_j and WQI_j. Only roads were assumed to cause significant sedimentation. Logging and cattle grazing were assumed to add primarily to nutrient concentrations. ORV use away from roads was assumed not be causing problems.

12. Runoff

The hydrologic relationships derived through the watershed modeling, when converted to the form required by the model, were:

yield: $WYLD_{j} = WYLD_{j}pres + \sum_{\ell} b_{j\ell} I_{PH\ell} + \sum_{\ell} c_{ij} CAT_{j}$ + $\sum_{\ell} s_{ij} SHE_{j}$ (80) peak flow: $PFLO_{j} = PFLO_{pres} + \sum_{\ell} r_{jp} I_{Rp} + \sum_{\ell} p_{j\ell} I_{PH\ell}$ + $\sum_{k} d_{jk} LOG_{k}$ (81)

- i = index on land units
- j = index on watershed units
- k = index on timber sales
- l = index on new mines

WYLD_{ipres} = present or baseline yield from j

 a_{jk} = change in yield in j per 1,000 bd ft harvest from k LOG_k = amount of harvest in timber sale k

5 _ 1 ¹ 111 1 C 1 1 1 . . .

 $b_{j_{\ell}}$ = change in yield in j from new phosphate mine ℓ

 $I_{\mathrm{PH}_{\sigma}}$ = binary variable on new phosphate mine ℓ

 $CU_i = consumptive use in j$

PFLO ipres = current peak flow in j

r_{jp} = change in peak flow in j from road network p

I_{Rp} = binary variables on road network p

C_{ii} = change in peak flow from cattle AUMs

 $CAT_i = cattle AUMs in i$

 S_{ij} = change in peak flow from sheep AUMs

 SHE_i = sheep AUMs in i

 p_{j_0} = increased yield from mine ℓ

 d_{jk} = increased yield from timber sale k

Runoff impacts of surface disturbing uses are expressed in terms of peak flows and annual yields. Cattle and sheep impacts proved negligible at grazing levels actually occurring.

13. Water quality

Three water quality indices were constructed. Nutrient loadings were assumed as contributions from logging and mining added to base values. Sediment loadings were assumed to be also caused by cattle, sheep, and roads.

Nitrogen: NIT_j = NIT_{baseline} +
$$\Sigma a_{jk} LOG_k + \Sigma p_{j\ell} IPH_{\ell}$$
 . . (82)
Phosphate: PHO_j = PHO_{baseline} + $\Sigma b_{jk} LOG_k + \Sigma q_{j\ell} IPH_{\ell}$. . (83)
Sediment: SED_j = (1.02) FLO_j + SED_{baseline} + $\Sigma c_{j,h} LOG_k$
+ $\Sigma r_{j\ell} IPH_{\ell} + \Sigma d_{ij} CAT_i + \Sigma f_{ij} SHE_j + \Sigma S_{jk} IRk$
. (84)
i = index on land units
j = index on watershed units

k = index on timber sales

l = index on new mines

m = index on road networks

NIT_{base} = baseline nitrogen index

PHO_{base} = baseline phosphate index

SED_{base} = baseline sediment index (12 mg/1)

 LOG_k = timber harvest from kth sale

 a_{jk} = change in nitrogen or j per 1000 bd ft from sale k (0) b_{jk} = change in phosphate on j per 1000 bd ft from sale k (0) c_{jk} = change in sediment on j per 1000 bd ft from sale k (0) $I_{PH_{Q}}$ = binary variable on new mine ℓ

 $P_{j_{\ell}} = change in nitrogen in j from new mine \ell 0.2 mg/l/acre mine$

q_{jℓ} = change in phosphate in j from new mine ℓ 0.2 mg/l/acre mine

 $r_{j_{\ell}}$ = change in sediment in j from new mine ℓ 12 mg/l/acre

d_{ij} = sediment from cattle AUMs

 $CAT_i = cattle AUMs$

 F_{ii} = sediment from sheep AUMS

 $SHE_i = sheep AUMS$

S_{jk} = sediment from road network k (1.0 per mi)

 IR_k = binary variable on road network k

151

P_{jm} = sediment change from mitigation project

 P_m = binary variable on sediment project m

 $FLO_j = flow$ in watershed j (flow in cfs)

The Modeling Process

The construction of a data file that describes the linear programming problem in a format compatible with commercially available solution packages can require extensive effort if done by hand. When the decision was made to use LP to generate Pareto optimal alternatives, little was known about the details, but it was obvious with 343 land units that the model could become quite large. Therefore, two computer programs were written to automate the process of model building and applied as illustrated in Figure 13.

The two programs were a preprocessor (that converts the raw data describing 343 land units into coefficients, right-hand sides, and bounds) and a matrix generator (that reads the output of the preprocessor and acts on a set of instructions to produce the desired LP problem file). Both programs were written in PL/I. The preprocessor is specific to this project in that it takes the raw data describing the Upper Blackfoot study area and generates the numerical values of the coefficients and right-hand sides of the equations for each land unit that makes up the linear model. Any change in the way these quantities are estimated is expedited by a programming change in the preprocessor. The computer programming is relatively simple and can be easily revised.

The more time consuming activity involved in producing a linear programming model is that required to specify the numeric values of the linear problem in the rigid format required by most LP packages. The process requires assignments of unique alphanumeric names to all rows and columns in the problem and of numeric quantities to all coefficients, bounds, and right-hand sides. For a problem of the size of that in this study, this amounted to the generation of several thousand records of alphanumeric data, with row and column names subscripted by use and unit. To speed the construction of this data set, a general purpose matrix generator (MG) was written and is reproduced in Appendix C. The MG reads and acts on instructions for rapidly generating row and column names, reading numeric information, performing simple computations on that data as necessary, and placing the results in a disk file in the proper LP format. The MG can handle binary and integer variables, as well as separable programming problems with convex sets. It generated the LP problems used in this study in less than 30 seconds of CPU time. Use of the MG facilitates rapid problem restatement as necessary and virtually eliminates the key stroke errors that typically plague models of this type.

The last step in the modeling process is the generation of a solution to the LP problem. This was done using the TEMPO linear programming package available on the University B-6800 computer.

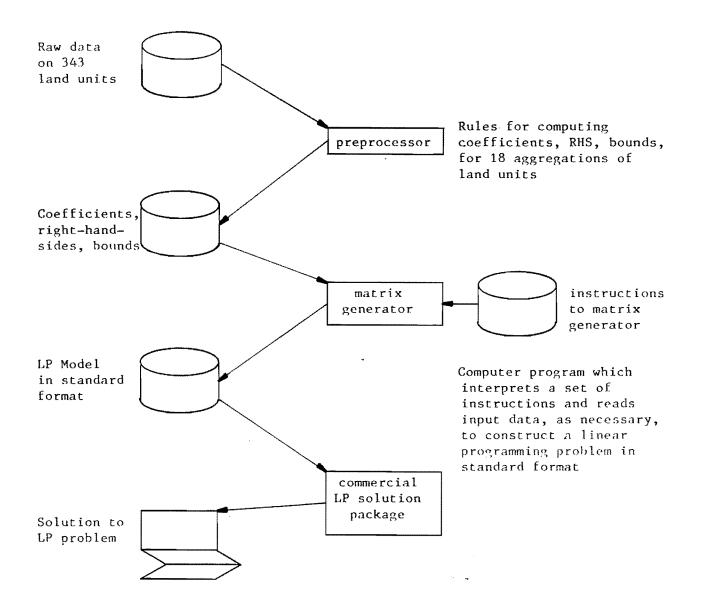

Figure 13. Construction of the linear programming model.

Results

The allocations of uses maximizing benefits are presented with the phosphate mine on Table 38 and without the mine on Table 39. The results minimizing energy consumption are presented on Table 40. As it turned out, phosphate mining completely dominates the other uses in terms of benefits, and a second optimization was run.

Without phosphate mining, the maximum benefit solution concentrates on logging development with associated firewood cutting and grazing by deer with associated hunting. Present observations and logical extrapolations favor a more mixed combination of activities. This information can be brought into the model by reducing the marginal economic values used for logging and deer to the lower values that would be associated with these high use rates. However, such adjustment runs did not seem warranted at this point because the analysis that could be consummated within the scope of this project proved to be heuristic rather than prescriptive. A prescriptive analysis would require careful review and revision of the entire process of data gathering now that an overall computational framework has been established.

Sensitivity Analyses

There is typically a wide range in the quality of the data available for planning. The values of some coefficients may be accurately known, while others may only be available as order-ofmagnitude estimates. Since the solutions obtained from the model may be sensitive to coefficients and constraint values for which the estimates are uncertain, sensitivity analyses are desirable. Most commercially available linear programming software packages have procedures for conducting post-optimal sensitivity analyses on righthand side values, on objective function coefficients, or on coefficients in the linear A-matrix. These procedures are collectively known as parametric analyses.

To perform a parametric analysis on a selected right-hand side, the constraint is written as

 $\sum_{j=1}^{\Sigma} a_{j} \leq b_{j} + \alpha_{j} \Theta \qquad (85)$

where

 α_i is the size of increment to be considered on bi

 $\Theta = 1, \dots, n$ are the numbers of the increments to be added

After each selected right-hand side is incremented by its particular α_i , the linear problem is resolved in a relatively few simplex iterations. The amount of change in the results indicates how sensi-

tive the solution (both the objective function and the model outputs) is to estimates of right-hand side values. Similar parametric methods are available for examining model sensitivity to objective function and A-matrix coefficients, though these are generally more costly to run. No parametric sensitivity analyses were performed on the LP model used in the study.

Another type of post-optimal analysis available on most commercial LP packages is RANGE analysis. This sensitivity analysis method requires no additional simplex computations. It produces information about the range over which the values of rows or columns can vary without changing the solution. For the LP/model used in the study, one RANGE analysis was conducted. It was done from an optimization run which maximized dollar benefits from the study area while limiting energy consumption to 5.617x1010 Btu (a midpoint between its values for the solutions without mining on Tables 39 and 40). The RANGE analysis indicates that the solution is not sensitive to any of the objective function economic coefficients, except those for firewood and fish and moose habitat. For these variables, the amount of use appears to be sensitive to unit benefits on relatively few land units. No other obvious points of sensitivity were found though it should be remembered that this type of analysis does not provide information on model sensitivity to A-matrix coefficients.

Alternative Futures

The linear programming model also provides a capability to consider potential future states. A future state defines the combinations of constraints used in the linear programming model. For example, alternative futures may be specified by a set of demands for forest products or a set of production levels for the commercial uses including the amount of phosphate taken from each mine and the locations of oil and gas exploration.

Continuing with this example, demand estimates for forest products can be made from regional population projections and assumptions on regional per capita consumption of those products. If firewood consumption is now 0.01 cords per capita and in 20 years the population of the region will double and per capita consumption of firewood will increase by 30 percent due to rising energy prices, then the per annum demand for firewood 20 years hence becomes 2.6 times the present demand. This number could then be used in an alternative future. A slightly expanded approach is to use three alternative futures, perhaps, high demands/production levels, low demands/production levels, and probable demands/production levels.

Alternative futures can also be used to display the use consequences of various societal goals. The model can also evaluate diverse goals for reasonability and compatibility.

In formulating the alternative futures, care should be taken to avoid demand sets that are infeasible (logically impossible). The analysis might explore a subset of the noninferior surface by selectively and systematically varying a few parameters of a "probable" future and observing the nature and degree of shifts in optimal land management projects and the tradeoffs these imply. .

CHAPTER 7

REVIEW AND CONCLUSIONS

Planning Complexity

This study provides an empirical example of the complexity of the diverse goals, activities, and interactions that belie the superficial simplicity in which comprehensive land use planning is often advocated. In the real world, many people engage in a variety of activities while pursuing diverse goals and thereby interact with one another in many ways. The principal need in planning to provide for an optimal mix of activities is to simplify this complexity, first by separating the important from the trivial (or at least minor) and then by providing a structure for identifying and examining the important tradeoffs.

Obviously, human goals are diverse. Each individual has a variety of goals and must weigh tradeoffs among them in decision making. Groups mean more goals, conflicting individual decisions, and political resolution of differences. In the high mountain context, the diversity of specific goals collapses into the two dominating general ones of economic gain and environmental amenity. The major differences in use preferences collapses into a conflict between economic development and environmental preservation.

People use (directly or in absentia) mountain areas to pursue both general goals through numerous activities. For this study, 21 activities or uses were defined and classified two ways (Table 7). Decision making can be dispersed or centralized, and the predominant goals can be economic or environmental. Also, these human activities occur in the context of various physical and ecological processes that can be considered as natural uses.

The planning complexity, however, comes less in defining the values or the activities than in identifying and quantifying interactions among activities. It is the interactions that cause participants in one activity to want another activity curtailed and that cumulatively set physical upper limits to use. However, these interactions have not been sufficiently well quantified for planning comparisons and uncertainty as to their nature and magnitude creates the primary constraint to planning objectivity.

Interaction Analysis

Interactions originate in both technical (physical) and social (psychological) relationships. Technical relationships affect other uses by changing the physical setting, and social relationships affect other uses by changing perceptions or the way people interface with one another within that setting. Both types of relationships may be either complementary (positive) or competitive (negative), and each activity both imparts and absorbs interactions. Using the three above activity classifications (human activity for economic gain, human activity for environmental contact, and natural uses), one can classify dominating interaction types as shown in Table 41.

As shown in Figure 9 and described in the associated text, technical interactions (primarily Interaction 1) can be either positive or negative. In aggregate, however, they tend to be negative and increasingly so with greater activity intensity. As greater amounts of an economic activity (lumbering, mining, or grazing) are undertaken, it tends to become increasingly competitive with other economic activities and with natural land uses. A few scattered mining or lumbering efforts can be separated from one another and absorbed much more easily by the environment than can major operations.

The effects of low levels of economic on environmental activities (Interaction 2) tend to be social in character and negative in direction. Economic activities tend to disrupt the environment in ways that reduce the satisfaction received by people pursuing environmental enjoyment. The effects of environmental activities on economic activities (Interaction 4) also tend to be social and negative. People visiting a high mountain watershed tend to interfere with local economic activities. The relationships tend to become increasingly competitive in both directions with greater activity intensity. Greater economic activity causes greater environmental disruption, and more environmental visitors create greater pressure to exclude economic activity from favorite areas.

The interactions among environmental activities (Interaction 5) are largely social in character and complementary at lower activity levels (recreationists prefer some other recreationists around to complete isolation and families are attracted to an area by possibilities for participating in more than one activity). However, they become competitive at high use levels (wilderness recreationists, while shunning complete isolation, have a low tolerance for crowding). In high mountain areas, one would expect environmental activity levels to be below the intensities at which the social relationships change from complementary to competitive. However, the empirical evidence is not clear, and different investigators have come to conflicting conclusions. Vaux and Williams (1977) found convenient access and aesthetic attractiveness to dominate the effects of congestion in explaining visitation to wilderness areas. Cicchetti and Smith (1973) stress the importance of going to a pristine wilderness where congestion is intolerable.

In reviewing the six interaction types in the reduced matrix of Table 41 (Interaction 1), one would expect the technical impacts to predominate in the area immediately surrounding economic development (separation of recreationists from mines or attraction of snowmobilers to roads for examples). However (Interaction 2), for the area as a whole, the negative social impacts of economic development on environmental activities may be even stronger. As one thinks along the

| Imparting Activity Group | Absorbing Activity Group (Table 7) | | | | | | | | | |
|--------------------------|---------------------------------------|-----------------------|--------------------------|--|--|--|--|--|--|--|
| | Economic | Environmental | Natural | | | | | | | |

^aLetters match Table 7.

bNumbers designate interactions discussed in the text.

spectrum of increasing activity intensity, economic uses can generally (Interaction 1) avoid one another at low intensities; and (Interaction 3) animals, fish, and runoff are relatively unaffected by use intensities that are very upsetting to wilderness recreationists. Also, low intensity activity by environmental users is (Interaction 4) unlikely to cause major harm to economic uses, and the (Interaction 5) particular set of environmental (recreation) uses occurring in Upper Valley are not highly complementary to one another. Certainly, (Interaction 6) the current low level of environmental use has little effect on the natural environment.

The negative technical impacts (Interaction 1) proved relatively easy to quantify for the planning model, generally in the form of restricting one use from an area already taken by another. However, separation becomes increasingly difficult with increased competition for land and water, and greater development intensities force planners toward multiple use designs that minimize conflicts between simultaneous or series uses among activities at the same location. Multiple use, already well engrained into Forest Service terminology, will be forced to move from multiple uses scattered over a watershed to multiple uses within a given land unit as natural resources become more fully developed. A better understanding of the interactions that occur at this level must be developed.

On another front, specific negative social impacts of economic on environmental activities (Interaction 2) are generally the first constraint to wilderness preservation that planners must face, but these constraints (like the tradeoffs above) are poorly understood. In the face of uncertainty, the tendency is to prevent all economic activity on principle rather than to weigh tradeoffs considering the economic loss associated with the environmental gain. For initial reconnaissance, Figure 9 identifies interactions that need to be watched for negative social impacts of economic on environmental activities. The primary impacts are those of lumbering, mining, and grazing on recreation. Recreation (Table 7) can be roughly divided between mechanized (firewood cutting, hunting, snowmobiling, and off-road vehicle use) activities and visits focused on a wilderness experience (hiking and camping, viewing the old Oregon Trail, and fishing). Seekers after a wilderness experience would generally be more sensitive to economic development, and these uses need to be particularly watched. They are shown in Figure 11 as impacts 16, 18, 22, and described in more detail in the accompanying text.

Negative social interactions are also significant in that they occur over areas much larger than land units and introduce many of the scoping issues discussed in the beginning sections of Chapter 5. Activities that are not wilderness oriented impact on wilderness activities over large areas and long time spans.

Recommendations for Continued Index Development

This study quantified goals, measured uses, and selected a combination of uses that maximized goal achievement. Yet, the exercise leaves a sense that optimality was not achieved. Probing shows the problem to be in representing interactions, the adverse effects of one use on another that initially motivated the comprehensive planning movement more than 50 years ago.

In fact, successful water and related land use planning is tied to understanding interactions among uses in a wide variety of local contexts. Once the interactions can be quantified, applications require data collection, indexing, analysis, and model building. The variety of contexts, volume of relevant information, and complexity of the relationships suggests a major research and implementation effort. However, available resources are limited; initiation of the systematic collection of many new data items is not now possible; and indexing efforts need to be directed toward cost effective contributions.

What directions are currently cost effective? The value of information to a decision maker is a function of its reliability and relevance. Reliability refers to the correspondence between the state of the world and what the information says is the state of the world. Relevance is determined by being perceived as germane (is it understandable? does it fit in a practical context?) and important (does it describe a feature of the world to which satisfaction of objectives is believed sensitive?).

Generating reliable information generally requires systematic measurement of carefully selected time series. For example, a wealth of data exists on the Upper Blackfoot, but we cannot feel very confident about model results. The data are not sufficient. The motivation to collect more time series, though, depends on the present perceived relevance of the data. Thus, a serious problem in inaugerating a good index system is that changing values may undermine data collection efforts by making them appear irrelevant over time.

This might lead one to recommend (or resign oneself to) less rigorous data collection because financial and political exigencies do not permit the luxury of full scientific rigor. In that case, one would want to focus on techniques for approximating desired indices with acceptable reliability.

Further review of the Upper Valley case study, however, suggests that the current need is not for an extensive program of indexing for planning applications. The greater present need is for research to develop indices suitable for scientific studies to develop relationships describing interactions and to develop models for defining collective interactive impacts. Such efforts do not have the high cost of nationwide data collection systems as they instead focus on specific areas for the limited times required to collect and analyze information for developing a needed understanding. They also draw attention to the real limitation to objective planning by demonstrating what is needed to make it a reality.

Contribution of this Study

The contribution of this study was in formulating and testing a structure that broke new conceptual ground even though it fell short of definitive quantification of desirable uses in the selected case study area. In the Upper Blackfoot study area, the demands for most uses are low. In fact, they are so low that decreasing marginal values are often more important than interactions in restricting activities. In other words, demands were insufficient for uses to reach levels at which interactions are significant.

This situation meant that interactions were difficult to quantify because the events to be observed occur infrequently. Even where observations could be made, the character of the interactions would be expected to change with increased use intensities. For example, the few hikers and fishermen are so dispersed that they are very difficult to locate and question to obtain needed information. When they can be found, their concepts of interaction are quite different than they would be if recreational crowding were severe. This quantification problem could be overcome, but the effort was not judged to be worthwhile in the context of this study.

The present uses of Upper Valley conflict little with the overall best public interest, a situation that can be expected to continue at least as long as market conditions depress mining and logging activity. If larger future demands should raise these activities to levels exceeding the public interest, regulations restricting use would probably provide the most effective control. Because both uses are controlled by centralized decision making (Table 7), such a regulatory program would not need to be structured to directly communicate with the public.

Reiterating, the major contribution of this study is a framework for analysis, a skeleton on which research needs can be identified and prioritized. Many needed techniques are obviously still in the developmental stage, and many more quantifications need refinement.

Major topics requiring refinement are 1) the estimation of technical impacts of economically motivated uses on each other and on the natural environment, 2) the perceptions of wilderness oriented recreationists of other uses occurring in the area, 3) characterization of the combination of attributes identifying the quality of an area for a use, and 4) characterization of overall planning models to represent the many levels and types of interactions.

It has become almost commonplace for modeling to go beyond the support capabilities of available data. The data that exist often do not match the needs of planning models. Because of the poor match, a great deal of the effort going into both model building and data collection is unproductive. A conscious effort is needed for better coordination between the two activities. Certainly, this study was halted by sparse information on where uses occur and how they interact with one another.

The important point here is that analytic models to identify and quantify tradeoffs are the planning tools of the future, and that too little effort is going into developing advanced information systems so that they can be used to collect and organize the data that will be needed. For example, remote sensing technology is moving forward rapidly, has many spinoffs that could be developed for water planning applications, and needs to be applied. Researchers at Utah State University can now count big game in specified areas by remote sensing.

Better data can give better results with existing models. However, as mountain areas become more intensively used, the uses will become more interactive. Perhaps input-output modeling concepts can be applied; more likely, some sort of nonlinear equation set will eventually be required. At this point, one can safely conclude that for the long run the development of nonlinear, interactive, dynamic models is just as important as additional data collection for better planning. But more sophisticated models cannot be developed without better data, and we must return to the theme of coordinating data gathering with model building.

Returning to the theme of this report, indexing has an important role in data collection, model building, and planning. For the present, the primary role should continue to be predictive (deriving relationships needed for planning) rather than evaluative (applied planning optimization). The modeling done for this study demonstrates that the definition of quantitative relationships needs to be given a higher priority than quantifying values people put on known situations. This study has provided a structure for formulating those indices and guiding the needed data gathering and analysis.

APPENDIX A

Questionnaire Procedure

1. Select 10 people responsible for managing or acknowledged as experts with respect to each of the 8 specialized uses. These are commercial timber, cattle grazing, sheep grazing, wildlife habitat, fish habitat, phosphate mining, oil and gas exploration, and watershed runoff.

2. Identify 10 people each who engage in each of the 7 public uses. These are firewood gathering, hunting, hiking, camping, snowmobiling, ORV use, and fishing. Total population questioned would thus be no more than 150.

3. The experts on specialized uses will be asked for information on their speciality use, what public uses they personally participate in, and for information on their preferences with respect to those public uses.

4. The participants identified with each of the public uses will be asked what other public uses they personally participate in and for information on their preferences with respect to those uses as well.

Information Sought from Questionnaire

1. Identification of attributes actually important to experts or those engaging in public uses.

2. Estimation of preferences by values for those attributes (or of ranges of values within which the use is favorably regarded).

3. Overall public regard toward (feeling of importance of each use) all 22 uses. The complete list of uses is relevant because of the need, for example, to differentiate between deer habitat and cattle range preferences.

4. Perceived complementary or interference interactions with other uses.

Instructions

Each person being interviewed has been identified either with one of eight specialized uses (commerical logging, phosphate mining, oil and gas exploration, cattle grazing, sheep grazing, wildlife habitat, fish habitat, or watershed runoff), or one of seven public uses (firewood cutting, hunting, hiking and dispersed camping, concentrationed camping, snowmobiling, summer ORV use, or fishing).

1. Ask Question 1 with respect to that particular use.

2. Ask everyone Question 2 with respect to all seven public uses.

3. Ask everyone Question 3.

4. Many of those being interviewed with respect to a specialized use will respond to Question 2 that they also engage in public uses. For those that do so, ask whether they engage in that use in the Diamond Creek area. If so, ask Question 1 with respect to each use (to a maximum of 7) that they engage in regularly or occasionally. If not, ask why they do not use the Diamond Creek area and write a brief explanation on the Question 1 form.

Many of those being interviewed because of one public use will respond to Question 2 that they also engage in other public uses. For those that do so, follow the above procedure with respect to those other public uses (to a maximum of 6).

5. Ask everyone Question 4 (keeping in mind supplemental special topics where appropriate).

6. Use S or P code on upper right hand corner to indicate respondent type.

P-1 Firewood Cutting

.

Rate the following factors (beginning with 1 for the most important) according to their importance to you in deciding where to cut firewood. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|--|--------|----------|
| Α. | Number of dead trees in the
immediate area | | |
| Β. | Size of dead trees | | |
| c. | Distance from trees to
place where you can drive | | |
| D. | Distance you have to drive
to get to the location | | |
| E. | Price per cord that you
would have to pay for fire-
wood | | |
| F. | Ownership of the land | | |
| G. | | | |

Identify areas on the attached map where you have cut firewood in the last three years.

P-2 Hunting

Rate the following factors (beginning with 1 for the most important) according to their importance to you in deciding where to hunt. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|-----------------------------|--|---------------------------------------|
| Α. | Predominant vegetation type | | |
| В. | Elevation | and the second | |
| с. | Nearby stream | | · · · · · · · · · · · · · · · · · · · |
| D. | Steepness of ground slope | | |
| E. | Ownership of the land | | |
| F. | | | |

Identify the species that you have hunted during the last three years _______

P-3 Hiking and Dispersed Camping

Rate the following factors (beginning with 1 for the most important) according to their importance to you in deciding where to hike or camp along the trail. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|---|--------|----------|
| Α. | Steepness of the ground slope | | |
| в. | Predominant vegetation type | | |
| C. | Elevation | - | |
| D. | Aesthetic quality of the site | | |
| E. | Amount of visable landscape | | |
| F. | Proximity to a running stream | | |
| G. | Following a road or main-
tained trail | | · · · |
| н. | Ownership of the land | | |
| I. | | | |
| | | | |

Identify routes on the attached map where you have hiked and locations where you have camped in the last three years.

P-4 Concentrated Camping

Rate the following factors (beginning with 1 for the most important) according to their importance in your selection of a campground. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|-------------------------------|--|----------|
| Α. | Predominant vegetation type | | |
| в. | View of mountains round about | | |
| c. | Aesthetic quality of the site | | |
| D. | Elevation | ······································ | |
| E. | Proximity to a running stream | | |
| F. | | - | |
| | | • | |

What specifically attracted you to a campground in the Diamond Creek area?

P-5 Snowmobiling

Rate the following factors (beginning with 1 for the most important) according to their importance in your selection of a place to snowmobile. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|-------------------------------|--------|----------|
| Α. | Ownership of the land | | |
| Β. | Steepness of ground slope | | |
| C. | Elevation | ,
 | |
| D. | Predominant vegetation type | | |
| E. | Aesthetic quality of the site | | |
| F. | Following a road or trail | | |
| G. | | | |

Identify areas on the attached map where you have snowmobiled during the last three years.

P-6 Summer ORV Use

Rate the following factors (beginning with 1 for the most important) according to their importance in your selection of a route for driving your ORV. Comments on what sort of situation you particularly seek with respect to each factor would be helpful.

| | | Rating | Comments |
|----|-------------------------------|--------|---------------------------------------|
| Α. | Ownership of the land | | |
| в. | Following a road or trail | | |
| c. | Elevation | | |
| D. | Aesthetic quality of the site | | |
| E. | Amount of visible landscape | | |
| F. | Steepness of the route | | · · · · · · · · · · · · · · · · · · · |

Identify areas on the attached map where you have driven your ORV in the last three years.

P-7 Fishing

Rate the following factors (beginning with 1 for the most important) according to their importance to you in deciding where to fish. Comments on what sort of situation you consider ideal with respect to each factor would be helpful.

| | | Rating | Comments |
|----|-----------------------------------|--------|----------|
| Α. | Size of stream | | |
| в. | Flow velocity | | |
| с. | Characteristics of the stream bed | • | |
| D. | Ownership of the land | | |
| E. | | | |

Identify areas on the attached map where you have fished during the last three years.

QUESTION 2. How frequently do you use the forest for each of the following activities?

.

| Alternative Use | Regularly | Occasionally | Never |
|--------------------|---------------------|--------------|-------|
| Firewood Gathering | | | |
| Hunting | | | |
| Hiking | | | |
| Camping | Antonio | | |
| Snowmobiling | March 1990 - Samuel | | |
| ORV Use | | | |
| Fishing | | | |

.

**

QUESTION 3: How desirable do you feel it to be for your community that each of the following uses occur within the Diamond Creek area?

.

Responses

.

| Desirable and use should be increased | +2 |
|---|----|
| Desirable but current use level about right | +1 |
| Doesn't make much difference | 0 |
| Undesirable and should be restricted | -1 |
| Highly undesirable and should be curtailed | -2 |

APPENDIX B

Estimation of Energy Consumption Coefficients

Energy consumption coefficients per use unit were estimated for the eleven commercial and recreational uses involving significant human activity in the watershed and by using information in Tables Bl through B4.

1. Commercial logging

Energy for logging is used in felling, bucking, skidding, and transporting to the mill. The basic equipment consists of a chain saw for felling and bucking, a caterpillar for skidding and loading, and a truck for hauling. Additional energy used in road construction was not included, although new roads are anticipated for Timber Creek and most other significant sites. Also, the energy use per MBF is sensitive to transportation distance.

Energy Consumption

| chain saw | 2 gal/day x 125,000 Btu/gal = 250,000 Btu/day |
|-------------|--|
| caterpillar | 0.5 x 270 x 0.63 ÷ 7.2 = 11.8 gal/hr x 136,000 Btu/gal |
| truck | 0.10 mi/load ÷ 6 mi/gal x 136,000 Btu/gal = |
| | 227.120 Btu/load |

Timber Production

chain saw 2 tree/hr x 160 bd ft/tree x 7 hr/day = 2,240 bd ft/day caterpillar 2.4 load/hr x 480 bd ft/load = 1,152 bd ft/hr truck 3,000 bd ft/load

(250,000 ÷ 2,240) + (136,000 ÷ 1,152) + (227,120 ÷ 3,000) = (111.6 + 118 + 75.7) x 1,000 bd ft/MBF = 305,300 Btu/MBF

2. Firewood cutting

Energy is used to cut and haul firewood. The typical equipment is a small chain saw and a pick-up truck.

Fuel consumption:

saw 0.75 qt/.67 hr = 0.3 gal/hr (3-4 in3 engine)
pickup 10 mpg

Production cycle

saw l hr/cd
pickup l cd/trip (trip = 24 mi in study area)

Table B1. Load factors for fuel consumption.

| Type of | Operat | ing Condition | ns |
|---------------------------|-----------|---------------|--------|
| Equipment Used | Excellent | Average | Severe |
| Wheel-type, on paved road | 0.25 | 0.30 | 0.40 |
| Wheel-type, off highway | 0.50 | 0.55 | 0.60 |

| Jet fuel (naphtha) | 127,500 Btu/gal = 35.54 MJ/l |
| Jet fuel (kerosene) | 135,000 Btu/gal = 37.63 MJ/1 |
| Lubricants | 144,400 Btu/gal = 40.25 MJ/l |
| Waxes | 131,800 Btu/gal = 36.74 MJ/l |
| Asphalt and road oil | 158,000 Btu/gal = 44.04 MJ/l |
| Petroleum coke | 143,400 Btu/gal = 39.97 MJ/1 |

.

SOURCE: D. B. Shonka, ed., Transportation Energy Conservation Data Book, 3rd Ed. (Oak Ridge Tennesse: Oak Ridge National Laboratory, Energy Division, February 1979, ORNL-5493 Special), p. A-5. SOURCE: Oak Ridge Associated Universities. 1980. Industrial Energy Use Data Book. Oak Ridge, Tennessee, pp. A-1, A-5. Energy use

(0.3 gal/hr x 125,000 Btu/gal. x 1 hr/cd) + 125,000 Btu/gal x 1 trip/cd) = 337,500 Btu/cord.

3. Phosphate mining

The energy expended in phosphate mining depends on how much material must be moved what distance to extract a ton of phosphate and on the processing done at the site. On the average, 3.5 tons of overburden is moved for each ton of phosphate. The average ton is moved 1,500 ft on the site, either to the plant or to a waste dump. The primary earth moving equipment, as indicated in the EIS, is a bulldozer and scraper. Fuel consumption for these vehicles is calculated as a function of horsepower, operating conditions and time in use. Productivity depends on vehicle capacity, speed and distance in the work cycle, and operating conditions. Vehicle specifications from Stubbs (1959) were used in determining fuel consumption and operating cycles. Energy use in beneficiation was estimated from fuel estimates given in the EIS (V.II, 4-34), reduced by a factor of 34/58 to adjust for lowered post-EIS expectations.

Diamond Creek extraction

Fuel Consumption

| dozer | $0.5 \ge 270 \ge 0.63$ | $3 \div 7.2 = 11.8$ | gal/hr x 136,000 Btu/gal |
|---------|------------------------|---------------------|--------------------------|
| scraper | 0.5 x 450 x 0.5 | $5 \div 7.2 = 17.2$ | gal/hr x 136,000 Btu/gal |

Production

| dozer | 25 cycle/hr x 7.2S cu yd/cycle x 0.22 cu yds phos/cu yd |
|---------|---|
| | x 2,300 lbs/cu yd ÷ 2,000 lbs/ton = 45.9 tons/hr |
| scraper | 8.9 cycles/hr x 30 cu yd/cycle x 0.22 cu yds phos/cu yd |
| - | x 2,300 lb/cu yd ÷ 2,000 lbs/ton = 67.6 tons/hr |

(11.9 gal/hr x 136,000 Btu/gal ÷ 67.6 tons/hr) + (17.2 gal/hr x 136,000 Btu/gal ÷ 67.6 tons/hr) = 23,740 + 34,604 = 58,344 Btu/ton

Diamond Creek beneficiation

Consumption

[(4.5 x 108 kwh x 0.9478 Btu/sec x 3,600 sec/hr) + (230,000 gal x
125,000 Btu/gal) + (170,000 tons coal x 2.62 x 107 Btu/ton)] x
34/58 = 3.528 x 1012 Btu (over mine life)

Production

 $34/58 \times 4.0 \times 10^7$ tons = 2.35 x 107 tons 3.528 x 10¹² ÷ 2.35 x 107 = 150,127 Btu/ton Transportation .

12 mi x 676 Btu/ton-mi = 8,112 Btu/ton 58,344 + 150,127 + 8,112 = 216,583 Btu/ton

4. Cattle grazing

Energy expended in cattle grazing is determined by the transporation required to get the cattle to their range and to monitor them during the grazing season. Estimates were based on an average round trip of 22 miles to bring cattle into the study area and on one 30 mile maintenance trip per week per 140 AUM during the 3.5 months of the grazing season.

Consumption

| cattle trailer | 22 mi/load ÷ 6 mi/gal x 125,000 Btu/gal x 2 trips/ |
|----------------|--|
| | season = 916,667 Btu/season |
| pickup | 30 mi/trip + 12 mi/gal x 125,000 Btu/gal x |
| | 12 trips/season = 5,750,000 Btu/season |

Production

| cattle traile | r 40 head | /season x 3.5 | AUM/head = | 140 | AUM/season |
|---------------|-----------|---------------|------------|-----|------------|
| pickup | 700 AUM | (200 head) | | | |

(916,667 Btu/season ÷ 140 AUM/season) + (3,750,000 Btu/season ÷ 700 AUM/season) 6,548 + 5,357 = 11,905 Btu/AUM

5. Sheep grazing

Estimation of the energy consumed in sheep grazing paralleled the approach for cattle, taking into account the following differences: more sheep can fit in a truck; one (cattle) AUM feeds more head of sheep; the sheep grazing season is shorter; sheep herders are continuously on site; trucking distances are shorter because of greater reliance on herding.

Consumption

| sheep trailer | 18 mi/load ÷6 mpg x 125,000 Btu/gal x 2 trips/season
750,000 Btu/season |
|---------------|--|
| pickup | 30 mi/trip ÷ 12 mpg x 125,000 Btu/gal x 4 trips/ |
| | season |
| | 1,250,000 Btu/season |
| herder camp | 60 days/season x 0.375 gal/day (kerosene) x 135,000
Btu/gal |
| | 3,037,500 Btu/season |

Production

trailer 80 sheep/load x 2 sheep months/sheep x .2 AUM/sheep
months
32 AUM

pickup 120 AUM (300 head) herder camp 120 AUM (300 head)

(750,000 Btu/season ÷ 32 AUM/season) + (1,250,000 Btu/season ÷ 120 AUM/season) + (3,037,500 Btu/season ÷ 120 AUM/season) 23,438 Btu/AUM + 10,416 Btu/AUM + 25,313 Btu/AUM = 59,167 Btu/AUM

6. Hunting

Energy in hunting is expended in transportation and energy used on site. A pickup with camper is assumed.

Consumption

pickup 30 mi/trip ÷ 10 mi/gal x 125,000 Btu/gal = 437,500 Btu/trip camper 255 gal/day x 135,000 Btu/gal x 1.5 days/trip = 50,625 Btu/trip

Production

pickup 3 hunters/trip x 1.5 days/hunter = 4.5 days/trip camper 3 hunters/camper x 1.5 day/hunter = 4.5 days/trip (437,500 ÷ 4.5) + (50,625 ÷ 4.5) = 108,472 Btu/day

7. Fishing

Energy in fishing is also expended in transportation and energy used on site. It was assumed that energy is used at the site in only 10 percent of the angler days.

Consumption

pickup 20 mi/trip ÷ 12 mpg x 125,000 Btu/gal = 208,333 Btu/trip camping 0.25 gal/day x 135,000 Btu/gal x 1 day/trip = 33,750 Btu/trip

Production

pickup anglers/trip x l day/angler = 2 days/trip camping 0.l camper/day (208,333 Btu/trip ÷ 2 days/trip) + (33,750 Btu/camp x .l camp/day) = 104,167 + 3,375 = 107,542 Btu/day

8. Hiking/dispersed camping

Energy in hiking and dispersed camping is expended in transportation and energy used on site. Most of the user days are accounted for by miners spending the summer in Upper Valley in camper trailers, so camp site energy use is proportionately higher than would be expected in areas of predominantly recreational camping. Consumption

| pickup | 24 mi/trip ÷ 10 mpg x 125,000 Btu/gal = 300,000 Btu/trip |
|---------|--|
| camping | .375 gal/day x 135,000 Btu/gal x 2.2 days/trip = |
| | 111,375 Btu/trip |

Production

| pickup | 20 campers/trip x 2.2 days/camper = 4.4 days/trip |
|---------|---|
| camping | 2.0 campers/camp x 2.2 days/camp x 1 camp/trip = |
| | 4.4 days/trip |

 $(300,000 \div 4.4) + (111,375 \div 4.4) = 93,494$ Btu/day

9. Concentrated camping

Energy in concentrated camping is expended in transportation, energy use on site, and campground maintenance. Maintenance combines general campground cleanup and repair at the opening of the season and the routine upkeep (e.g., trash removal).

Consumption

| camper/trailer | 16 mi/trip ÷10 mi/gal x 125,000 Btu/gal =
200,000 Btu/trip |
|------------------|---|
| camping | 0.375 gal/day x 135,000 Btu/gal x 2.2 days/trip =
111,375 Btu/trip |
| a) routine maint | enance 20 mi/haul ÷ 10 mi/gal x 125,000 Btu/
gal = 250,000 |
| b) seasonal main | tenance 20 mi/trip ÷ 8 mi/gal x 125,000 Btu/gal
= 312,500 |

Production

| camper/trailer | 3.5 campers/trip x 2.2 days/camper = 7.7 |
|----------------|---|
| camping | 3.5 campers/trip x 2.2 days/camper = 7.7 |
| maintenance | a) 8 days/can x 15 cans/trip = 120 user days/haul |
| | b) 1000 days/trip |

(200,000 Btu/trip ÷ 7.7 days/trip) + (111,375 Btu/trip ÷ 7.7 days/trip) + (250,000 Btu/haul ÷ 120 days/haul) + (312,500 Btu/trip ÷ 1000 days/ trip) = 25,974 + 14,464 + 2,083 + 313 = 42,834 Btu/day

10. Snowmobiling

Snowmobiling consumes energy in transporation of the snowmobile and its use on site.

Consumption

| pickup | 10 mi/trip ÷ 10 mpg x 125,000 Btu/gal = 125,000 Btu/tri |
|------------|---|
| snowmobile | 50 mi/trip ÷ 35 mi/gal x 125,000 Btu/gal = 178,571 Btu/ |
| | (440-500 cc engine) |

Production

pickup 3 riders/trip x l day/rider = 3 days/trip snowmobile 1.5 riders/veh x l day/rider x 2 veh/trip = 3 days/trip (125,000 ÷ 3) + (178,571 ÷ 3) = 41,667 + 59,524 = 101,191 Btu/day 11. ORVs

Offroad vehicles may be either two or four wheeled. Motor bikes are assumed to be carried (not ridden) into the study area, and four wheel vehicles are assumed driven in.

a) Motorbikes

.

Consumption

| transport | 16 mi/trip ÷ 10 mi/gal x 125,000 Btu/gal = 200,000 |
|-----------|--|
| 1 | Btu/trip |
| motorbike | 40 mi/trip ÷ 35 mi/gal x 12S,000 Btu/gal = 142,857
Btu/trip |

Production

| transport | 3 riders/trip x l day/rider = 3 a days/trip |
|-----------|--|
| motorbike | 2.0 rider/bike x 1.5 bikes/trip x 1 day/rider =
3 days/trip |
| | |

 $(200,000 \div 3) \div (142,857 \div 3) = 66,667 \div 47,619 = 114,286$

b) Four wheel drive

Consumption

```
road 16 mi/trip ÷ 10 mi/gal x 125,000 Btu/gal = 200,000 Btu/trip
offroad 40 mi/trip ÷ 8 mi/gal x 125,000 Btu/gal = 625,000 Btu/trip
```

Production

road 3 rider/trip x 1 day/rider = 3 days/trip
offroad 3 rider/trip x 1 day/rider = 3 days/trip
(200,000 ÷ 3) + (625,000 ÷ 3) = 66,667 + 208,333
275,000 Btu/trip

.
