Abstract

Comprehensive planning is an elusive ideal. The practical planner must sort the relevant information from the vast amounts of data that modern technology can collect. The objective of this study was to use the Upper Blackfoot watershed in the mountains of Southeastern Idaho as an arena for developing methods for construction, refinement, and application of indices needed to design land and water management schemes, compare alternatives, and influence the public in their uses of the area. A total of 21 uses were examined on 343 land units of a 160 square-mile area ranging in elevation from 6300 to 9000 feet and where the principal activities of grazing, lumbering, mining, and recreation can only be undertaken in the summer after the snow has melted. The indices considered were a reasonability index for screening out unreasonable uses at the start of the planning process, an index of use intensity for estimating an amount for reasonable uses, and an index for estimating the utility of the amount of use made from the public viewpoint. Data were collected on 43 attributes for the 343 land units and used in a linear programming model to maximize 1) economic benefits from use of the area and 2) minimize environmental disturbance. The resolution in the available use data limited the model solution to allocating uses among 18 larger land units. The primary factor limiting the modeling, however, was the lack of information for defining the interactions among the uses. The analysis provides a framework for classifying and identifying interactions beginning with the simplest case of simultaneous use by two uses in near proximity. The contribution of the study was a framework for analysis and the identification of the needs for research on the physical interactions among simultaneous uses, the perceived interactions of simultaneous users, and characterization of attributes for defining the quality of an area for a use.

CHAPTER 1

INDEXING AS A PLANNING TOOL

Water resources development supplies water for municipal and irrigation uses, generates hydroelectric power, controls floods, and provides facilities for outdoor recreation. Land resources development provides sites for cities and farms, minerals, and recreation open space. Often these and other land and water uses conflict with one another and management is required to integrate multiple uses in the public interest. The task of management has been made increasingly complicated as more people employing higher levels of technology use more of nature's fixed resource base. Further development for still greater use requires larger projects with greater energy consumption. The resulting fuller resource utilization reduces the management flexibility previously associated with under-used resources and simultaneously increases the number and the complexity of the interactions among physical, economic, ecologic and social factors in natural and human environments.

For example, as larger demands exhaust local water sources, new water supply facilities must be more massive. The needed projects have greater direct impacts and, in a more interactive world, more numerous and lingering indirect impacts. Interactive effects alter vegetation, change flow regimes, spread pollution, and reshape aquatic environments.

Planning is the art of anticipating impacts and adjusting development plans and management policy accordingly. Planners strive to achieve ever expanding human goals for a better life within ever tighter constraints. Their ideal is to be comprehensive, to estimate every impact, to evaluate every interactive relationship, and to use the information in the objective maximization of social goals.

For years comprehensive planning has been the accepted rhetoric. Ideally, its pursuit should begin with research defining the effects of natural resource uses (individually and interactively) on the total environment and proceed with applications, monitoring and refinement through experience. For the most part, comprehensive planning has not worked this way. One sees instead data collection ad infinitum, with minimal quality control on the measurements, no consistency on measured items from one project to the next, and little depth of interpretation.

Comprehensive planning remains elusive. Instead of eliminating surprises in the objective maximization of human welfare, the multiplication of data has made planning more costly and more time consuming. Presentations have grown more difficult to understand, partly because of their bulk, but also as the coverage of additional interactions adds new concepts and new technical terms to the planning vocabulary. As fuller natural resource use causes more interactions, as new instrumentation increases the capacity to collect data, and as faster computer systems can massage more numbers into more forms, the mass of data available for planning grows geometrically. However, the process cannot just continue to add inputs to decision making without causing overload and breakdown. Well intentioned planners take great time and cost checking out inconsequential details. Masses of unconnected data are misapplied by people of diverse viewpoints and sometimes ulterior motives. Issue resolution is delayed as bad cases are made stronger by proponents with more facts. Planning productivity plunges. Information overload is counterproductive to objectivity.

In conclusion, the need for comprehensiveness has led to form without substance. As one example, the legal requirements for environmental impact statements are satisfied if information is made available; integration into decision making need not be demonstrated. The planning process needs a way back to anticipating important impacts and delivering information that promotes the good and hinders the harmful.

It is just not practical to approach comprehensive planning by presenting all the data that modern technology can collect. The trend toward information overload must be counteracted by 1) collapsing data (reducing their bulk for a given content) and 2) displaying differences among alternatives quickly and efficiently in understandable form. Collapsing data reduces redundancy, and efficient display facilitates thoughtful comparison of alternatives. Improved data management is essential to improved planning productivity. Indexing can provide the needed framework.

Index construction (expressing extensive information into a few indicators of processes or states) needs to begin from sound scientific principles. Principles from the physical sciences can be applied in engineering design to assure functional performance. Principles of economic efficiency can be applied to maximize net benefit. Principles of environmental protection and social well-being can be used to protect these vital systems. For example, environmental health is found in the stability of a mature ecosystem, and social health is found in human satisfaction and fulfillment (James et al. 1978a).

Scientific principles are important in organizing information for objective choice, but planning is not rote implementation of measures selected through a model of scientific rationality. It is not ethically acceptable to let scientific optimization dominate the fundamental precepts of free choice. People are not inert objects to be manipulated by modelers. What is best for a person depends not only on objective observations of how he or she is affected, but also (probably more so) on how he or she feels about it. The planning process should, according to the democratic ideal, culminate not in implementation but in display that conveys understanding.

While resource management decisions are ultimately political, scientific relationships constrain the choices. Counterproductive political controversy and political selections of choices impossible (or impractical) to implement can be reduced by better understanding, more careful application, and clearer exposition of scientific principles.

In order to search out how people feel, planning has married the ideal of scientific understanding to the ideal of public participation, broadening the base of decision makers to all who care. People are asked what they want; often through leading questions on how they feel about what planners propose. In soliciting responses, planners face the practical problems of presenting scientific information so that a nontechnical public can make rational decisions and can negotiate compromises when groups have differences in preferences.

After a choice is made, one step remains; implementation. Most land and water uses are not made directly by governmental planners. The decisions are implemented by influencing people toward uses deemed in the public interest (James 1975). Decision making requires passive consensus; implementation requires active concensus or going out to do something in the spirit of the decision. There is a big difference. As an example, Clark et al. (1971) found distinct differences between campers and campground managers over the types of activities best meeting common goals. The implementation process will probably always disclose sources of disagreement unanticipated during the plan's development. But without systematic information collection, these disagreements may go unnoticed or misdiagnosed, and resources managers may design implementation programs that are undermined by public opposition.

All three planning processes (scientific evaluation, public participation, and plan implementation) are facilitated by objective information. The quality of the planning product is determined by how well and how widely relevant information is identified, collected, collapsed into succinct form (indexed), presented (displayed), and understood.

Scientific facts are needed by designers for performance evaluation. Facts on both sides of tradeoffs must be presented in good faith as planners interact with the public in policy formulation. Motivating facts must be convincingly presented to get potentially nonbelieving land and water users to follow public policy.

For developing indices that efficiently display the important factors from a mass of complex information for these three applications, the questions of interest are: What do people (designers, deciders, users) want to know? What forms (varying both among and within the three groups) communicate that information best? What appeals do best in encouraging individual users to conform to collective decisions on public interest? What index and display systems promote decisions that give those making them long run satisfaction? People want assurance that an alternative will perform. In making up their minds, they want to know how alternatives differ in effects on the things they value. They want technical detail collapsed into the essence of worthwhileness or objectionability.

Collapsing data into fewer indices, however, results in information loss, and attention must be given to preserving the information content most meaningful to users. Information content can be technically defined and provides a statistical criterion for evaluating how much additional information a new index adds. Other criteria must be applied in determining how useful the information is. These criteria grow out of the needs of the three planning processes: importance in the technical interactions governing design, relativity to values governing group consensus, and contribution to getting user groups to conform to collective choices. In order to avoid information overload, interactions of secondary concern or influencing the decisions of few users may have to be omitted when making tradeoffs in index development.

The system designer, policy decider, and water user can all work more efficiently with a few indices relating to basic values. Designers seek performance; policy deciders seek economic efficiency and a few other social objectives; water and land users are concerned with personal economic, environmental, and social goals. Because different groups want different indices, more indices must be developed than are of interest for any one purpose.

The objective of this study was to use a high mountain watershed in southeastern Idaho as an arena for gathering facts and developing methods for the construction, refinement, and use of indices which capture the economic, social, and ecological impacts needed to guide land and water management schemes, compare alternatives, and influence uses. A high mountain watershed was selected as a site where land and water management presents issues on which many people feel keenly in a setting where most uses are light and the interactions (at least the social ones) are relatively less complex than those that occur with the greater number of actors in more densely populated areas.

The indexing was to 1) employ known physical, biological, and perceptual relationships in hypothesizing the determinants of land and water use, evaluating uses according to the public interest, and estimating competing or complementary interactions among uses, 2) use historical data to assess the reasonableness of these relationships, and 3) construct a model permitting planners and the public to see the implications of alternative choices. A capability to forecast the implications of alternatives and express the important implications in indices representing priority concerns is an invaluable deterrent to regretted choices; it is the hope for comprehensiveness in planning; it is the foundation for monitoring to be sure that all remains well.

4

CHAPTER 2

PRINCIPLES OF INDEXING

Introduction

Indices capture the important information content for three major applications; to 1) define relationships among variables for development or management design, 2) forecast development or management results for evaluating alternatives, and 3) motivate cooperation among diverse interests in implementation. The first role is primarily scientific or predictive. The second and third roles are both evaluative with the second addressing evaluation from the overall public interest and the third contributing to evaluations from the viewpoints of the particular interests of specific groups or individuals.

Economists have used indices for years in watching changes in prices or economic productivity. In the last 25 years, both the predictive and evaluative roles of indices have been expanded conceptually.

Tinbergen (1952) introduced and Land (1974, 1975) refined the combined use of policy instrument (manipulable) indicators, initial state (nonmanipulable) indicators, and output indicators depicting direct results and side effects (Figure 1) for examining economic policy alternatives. Their configuration uses indices to compare the utilities of outcomes, but it also draws attention to the applicability of indices in defining causal relationships for use in predicting outputs from input factors. Such defined causal relationships can be used to forecast the influences of both exogenous and controllable variables on the output variables. Conversely, they can also be used to identify the values of the controllable variables necessary for the planner to achieve a "desired" outcome. Fox et al. (1966) define the two-way use of these constructs as "consistency modeling."

For both predictive and evaluative applications, index construction begins by applying statistical techniques to reduce redundancy. For predictive applications, selection of the relevant information content requires identification of the applicable laws in the physical, economic, biological and social sciences. For evaluative applications, selection requires information on how people feel about the futures predicted for them.

The Data Base

Index development starts with a system to be examined and a purpose for that examination. For planning purposes, one needs to know the

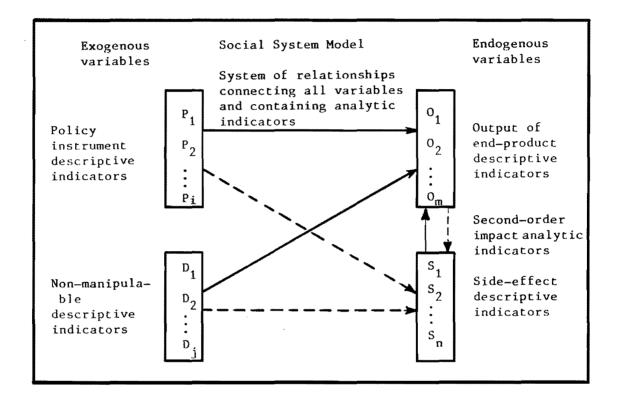

Figure 1. Kinds of indicators and their relationships (from Land 1975).

state of the systems and how the factors describing that state interact with one another. Descriptive information must be collected to begin the study.

Limitless indicators can be used to describe the states of the physical, economic, ecologic, and social systems existing at a given time on a given area of land. Some are very simple; others can only be measured with sophisticated instruments by people with special interpretive training. Relevant measurements must be selected and made, and the mass of data then has to be reduced so that the information obtained can be applied.

Statistical Analysis

The collected data need to be examined for redundancy; correlations need to be identified so that total information can be expressed with fewer numbers. Each number needs to be scaled so that changes in its magnitude can be properly interpreted.

A variety of statistical methods has been proposed for these purposes (Gum 1973, 1974, 1976; Arthur et al. 1976). Mahmood and Messer (1982) outlined the combination of factor and principal components analyses used in formulating water quality indices for this study. Stevens (1946) identified four empirical operations in constructing scales as the determination of a) equality, b) greater or less, c) equality of intervals, and d) equality of ratios. A nominal scale is based only on the first; an ordinal scale is based on the first and second; an interval scale on the first three; and a ratio scale on all four (Metfessel 1947). Ranking provides only an ordering of items with respect to preferences. Rating also provides the distance between points on a preference scale. Comparative techniques add a zero point and thus allow such ratio comparisons as A being preferred twice as much as B.

Construction of rankings, ratings, and comparison ratios requires different information processing algorithms. Possibilities include but are not limited to:

- 1. Ranking average rank of each item over the sample
- 2. Rating
 - a) average rating for each item over the sample
 - b) ratings calculated from Theory of Signal detection methods (Swetts et al. 1961; Daniel et al. 1971)
- 3. Comparative judgment
 - a) general allocation of points among all categories (Metfessel 1947; Gum 1973)

- b) ratio scale calculated by rational origin method based on paired comparison (Thurstone and Jones 1959)
- c) ratio scale based on paired allocation of points (Comrey 1950)

For mathematical manipulations, such as combining indicators into indices, the value weightings must have ratio scale properties. The tests used in the social sciences for these properties are the Comrey Paired Allocation Test and the Gum General Allocation Test.

Indicators that pass the test can be combined into indices through a function of the form

 $P = x^{b}y^{c}z^{d} \qquad (1)$

where, for example,

P might be an index of recreation

x might be an indicator of fishing

y might be an indicator of camping

z might be an indicator of hunting

The exponents b, c, and d define the relation of the indicators to the perceived overall recreation value. Gum (1973) explains the theoretical basis for converting the preference measures obtained from the Comrey or Gum tests to the exponents in Equation 1. Other methods for incorporating preference information into indices have been proposed by Brown et al. (1970, 1971), Crawford et al. (1973). The selection of appropriate means depends on the theory used in specification of the indicator (Biderman 1966), on the information needs of the potential users (De Neufville 1975; Garn et al. 1976), and on the mathematical properties of the indicators to be combined (Kruskal 1968; Osborne 1976; Ott 1978).

Predictive Effectiveness

The best predictive indices are obviously those that are key variables in a causative relationship. Where a causative relationship is known, indexing becomes a task of finding the best way to measure a needed variable in the given field situation. Where the causative relationship is not known, indexing becomes a task of identifying plausible factors and then testing them by statistical or other means. In either case, the effectiveness of an index as a predictor is evaluated scientifically. For evaluative applications, indices must also be concensus acceptable to those using them. De Neufville (1975, Ch. 10) describes how a social indicator must be institutionalized to affect decision making. Institutionalization legitimizes concepts and ensures continuing measurement of the indicator. The elements of institutionalization are:

1. The concept of the indicator meshes with user perception of relevance.

2. The agencies that collect and massage the data are respected, and their measurements are free from political control.

3. Long term financing for regular measurement is dependable.

4. The data are presented in a nonpolitical context.

5. Informed, active interest groups use and support continuance of the data series.

6. The media and the public are conscious of the indicator's existence and its role.

7. Processes are established and followed for orderly refinements in concepts and methods to update the indicator.

8. The indicator is tied into particular programs as a criterion for funding or a trigger for operation.

9. The indicator is tied into the conduct of policy to which government is committed.

10. Governmental or quasi-public groups use the indicator in formulating policies.

Items 1, 2, 6 and 10 in De Neufville's list vary among different index user groups according to both their desired application and level of analysis (Larson et al. 1979). Much of the work to define social indicators has been done from a national perspective. Little attention has been given to indexing to serve the policy needs of state and local jurisdictions or to support appeals to resource users to follow the public interest in choosing among available alternatives. The focus of this study on small mountain watersheds and on information needs at local and individual levels is breaking new ground in index application to the local arena where land use planning occurs in the United States.

Considerations in Defining Evaluative Indicators

Analytic Approach

Evaluative indicators, those for comparing the utilities of alternatives, have received the most attention; and, of these, economic value (benefits net of or divided by costs) has often had the bottom line in decision making. However, environmental movement now has planners looking more broadly and uncovering areas where individual viewpoints vary and consensus is more difficult to reach.

Two principal approaches have been used in the search. One popular approach ("Toward a Social Report," U. S. Department of Health, Education and Welfare 1969; Techcom (the Technical Committee) 1971, 1974) has been to identify reasonable goals for society and then reason increasingly detailed objectives until reaching a set of measurable indicators. The "Principles and Standards" (U.S. Water Resources Council 1973) were built by this intellectual exercise.

Synthetic Approach

In contrast to the above analytic approach, the synthetic approach (Andrews and Withey 1976) identifies popular concerns by public survey techniques. General concerns are translated into specific criteria, and indicators are constructed to represent these criteria. Of the two methods, the synthetic approach seems far more useful for establishing indices that explain the tradeoffs made among diverse groups in reaching a consensus or that can be used to encourage implementation. Different viewpoints can be ascertained by surveying various groups much easier than they can be determined analytically. Further illustrations and applications are provided in Finsterbusch and Wolf (1977).

Hierarchy of Indices

When selecting indices of value, one should cover the important values; but there is no need to add indices that restate values already contained in accepted indices. Human values can be broadly classified as economic, ecologic, and social. The logical approach to minimizing duplication was to begin with the economic index, try to capture as much residual information as possible in the second index, and continue in this manner to cover the important effects. The specific strategy was:

1. Forecast economic consequences and express them in estimates of net benefits.

2. Assuming the second ranking value in mountain areas to be preservation of the natural environment, identify environmental values not covered by the economic analysis and convert them into an index measuring net environmental impacts. 3. Identify social values not covered by the economic and environmental indices. For example, human well-being may suffer when opportunities for mountain experiences are reduced.

4. Assess a) whether the indices agree with index user perceptions of importance and b) whether measured values of these indices satisfy user information needs.

Economic Aspects

Economic activity in a high mountain watershed is largely driven by forces operating within a larger economy. Schumpeter (1961) attributes development in the economy at large to one or more of new combinations of productive resources. These are: introduction of a new good, introduction of a new production method, opening of a new market, development of a "new" raw materials supply, and modification of the way industry is organized. Mountain areas primarily supply raw materials, including both commercial products and natural environments for recreation experiences.

Maki (1968), MacMillan (1968), and MacMillan et al. (1968) describe economic development as encompassing greater resource productivity, a wider range of real choice for consumers and producers, and broader clientele participation in policy formulation. All three apply to mountain areas.

Economic development in high mountain areas thus implies greater rates of extraction of both renewable and nonrenewable resources, and more recreation facilities. Decisions to make greater use are made by individual users (recreationists, cattlemen, lumber company managers, etc.) interacting with resource managers (U.S. Forest Service officials, water quality control officials, etc). The users are motivated more by profits and personal satisfaction, and the managers are motivated more by overall net benefits to whomsoever they may accrue.

Both sets of decision makers need reliable information on the costs and benefits associated with particular actions at particular locations. Site development costs vary greatly over small distances, but benefits are much the same wherever a use occurs. Consequently, the economic indices emphasize 1) the benefits of resource development (use) from the national viewpoint and 2) the costs of development (use) at the specific site from the viewpoint of the private sector. Local (traditionally called secondary) benefits and national costs are recognized to exist but assumed to be much smaller in magnitude.

Environmental Aspects

The environmental values of a high mountain area that does not contain unique wilderness features are largely associated with aesthetics and runoff. The quality of the aesthetics and the amount and quality of runoff are in part determined by biological activity that may of itself have additional long term environmental values.

Preservation of these environmental values thus requires that settings of high aesthetic character or that generate high quality runoff be protected. Special attention needs to be given to protecting runoff when managing mountain area land use because of the importance of mountain areas as a water source, the dependence of runoff quantity and quality on catchment characteristics, and the potential alteration of those characteristics by commercial or recreational use. Meaningful evaluation and land use changes require quantitative relationships for estimating land use impacts. However, derivation of adequate relationships is complicated by the fact that neither quantity nor quality are simply conveyed in a single measurement. Quantity is a total volume, but water users also need information on how runoff is distributed within the year and varies from year to year. Quality is a collective concept combining innumerable parameters to define water pollutants and their effects. However, the number of indices that are needed to establish reliable predictive relationships are fewer than one might expect. The basic uses of mountain lands are few, mountain areas classify into relatively few ecosystem types, and downstream users are concerned with relatively few quantity and quality parameters.

In selecting runoff indices, one needs to cover runoff quantity and quality characteristics that affect either instream or diversion uses. For example, the use of water for drinking is limited by viruses, bacterial pathogens, toxic heavy metals, and many organic compounds. Activities that increase concentrations of these variables shift water to less productive uses. Where the original uses are still permissible, reductions in the value of water should be estimated (Helweg and Alvarez 1980).

Instream values depend on the health of the aquatic ecosystem. Aquatic ecosystems possess two complements, the abiotic environment and the natural community. Assuming that the geologic and climatic features are relatively constant, within the annual cycle of seasons, a steady state develops within which solar energy flows into the natural community, is processed by various life forms, and is released as heat or productivity. A steady state of annual cycles is maintained as long as the pattern of energy and material inputs continues. Ecosystem stress occurs with the expenditure of energy in disrupting the system. Ecosystem stability (resistance to stress) is a function of diversity (Margalef 1968) or the number of ecological niches or functional roles that exist within the community.

A climax community generally has maximum diversity and is reached at the end of successional steps that result from competitive changes within the ecosystem and occur in a systematic and definable manner. The climax reached at a given location depends on environmental variables (hydrologic, soil, physiographic, climatic, and other factors). Carrying capacity can be defined only under steady state conditions for a climax community.

One can logically hypothesize ecological maturity as the ideal state for the environment at a given location. However, it is one that conflicts with use of the same area by the human economy. Some natural environments have to be sacrificed. In deciding which ones, the planner must recognize that some mature ecosystems are more productive, aesthetic, or unusual than others. One general index to the value of a mature ecosystem is the time nature required to achieve it (James et al. 1978b). The time depends on the life-spans of the predominant species in the various stages of the succession toward maturity; for example, a mature forest environment takes much longer to achieve than does a mature grassland environment.

For quantifying the quality of a specific ecosystem, a watershed can be divided into i ecologically homogeneous areas, A_i as illustrated in Figure 2. The j possible uses for the areas can then be listed as U_j . For ecologically homogeneous area A_i , one can visualize environmental factors E_1 and E_2 as controlling the carrying capacity for (ability of the environment to support) use U_1 (Table 1). Some other indicator, E_3 , may be more reasonable for estimating the carrying capacity of A_1 for use U_2 . A still different combination of indicators, E_2 and E_3 , may represent the carrying capacity for use U_1 of area A_2 . Other areas and uses could have still different combinations.

Human energy expenditure on a land area may increase populations of some species to more than their carrying capacity (agriculture, tree farming, range seeding, etc.), decrease populations until a climax species can no longer sustain itself (clearcutting, burning, etc.) and faster-growing species take over, or change the carrying capacity by altering populations of supporting or competing species. Specific changes depend on the amount and form of energy expenditure.

Social Aspects

The social values of a high mountain area are largely found in their satisfaction of the human need for wilderness experiences. Social-psychologists and mental health researchers have long recognized that people are affected by their environment. Social-psychological literature suggests that physical and mental health are fostered by self-actualization. Specifically, a person profits by encountering, coping, and surmounting a variety of obstacles that are challenging, but not so hostile that life or the will-to-live is destroyed.

For the purpose of this research, social indices may be considered in analogy to the relationship of environmental indices to ecological maturity. The effect of a uniform environment (whether natural or social) is to diminish the quality of life. People are made happier by environmental diversity. A succession exists in that a person is attracted to a new environment; but as his needs for the experiences that it provides are met, he shifts to other environments for still new experiences. Eventually a person reaches a state ("maturity") that balances the environmental experiences in a manner best meeting his or her needs (maximizing his or her health).

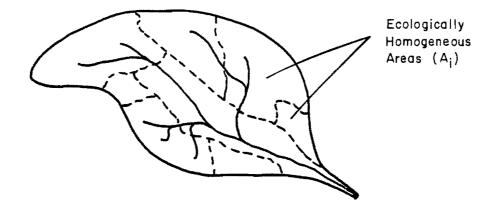

Figure 2. Illustration of watershed subdivision for ecological analysis.

Table 1. Index combinations used to evaluate the environmental quality of a specific ecosystem.

Uses	<u> </u>	Homogeneous Areas	Ai
	L		
U1	E1,E2,	E2,E3	
U ₂	E3		

Note: The Es are hypothetical environmental indices of the carrying capacity of a specific ecosystem subarea.

The combination of environmental experiences best for an individual varies with culture, social background, age, physical condition, and other personal characteristics. Strictly speaking, each individual has his own ideal environmental experience. The practical problem is to index health and environmental factors so that indices can be derived and the concept can be made operational (Brogan and James 1980). One advantage of selecting a high mountain watershed to consider indicators of social value is that the number of likely causative linkages between environment and health are fewer than they are in environments where people live and work.

Five major conceptual linkages have been proposed for explaining how the physical environment affects human well-being: physiological change (MetroStudy Corporation 1972), territoriality (Lyman and Scott 1967), personal security (Glass and Singer 1972), environmental control (Hill and Meek 1971; Perlmuter and Monty (1977), and social communion (Hirschi 1969; Cassel 1971). James et al. (1974) found the last of these to be the most significant in the relationship between people and their residential environment in Atlanta, Georgia.

In mountain watersheds, one might expect the following relationships:

1. Physiological change: The fresh air and exercise of wilderness experiences benefit physical health. On the negative side, one can visualize wilderness accidents or disease brought on by exposure to the elements (for example, being drenched by a summer thundershower).

2. Territoriality: Visitors to wilderness areas are not willing to accept the same frequency of intrusions by outsiders as people are in other environments. Some intrusions do not even require the personal presence of the intruder but only refuse, crushed plants, trail erosion, or other evidence of his having been there.

3. Personal security: Visitors to wilderness areas can be frightened or harmed by wildlife or by other visitors, by becoming lost, or by perceptions of hazardous conditions.

4. Environmental control: Visitors to wilderness areas come with preconceptions of the environment that they would like to see and are disturbed by encountered degradation. Even people who do not visit may feel offended at hearing of such changes.

5. Social communion: Visitors to wilderness areas can draw closer to accompanying family or friends or become better adjusted through escape from people or cares left behind.

Implementation Applications

Planning decisions on land and water uses are implemented through indirect means such as regulation, charging, and information dissemination. All too often, the regulatory process is assumed to achieve total compliance at zero cost. In actuality, regulation involves cost, and some activities are much more costly to regulate than are others. Information dissemination can facilitate compliance and reduce regulatory costs. Charging schemes provide incentives, help defray management costs by raising revenue, and ration use according to need.

Watershed planning needs to optimize in terms of maximizing the benefits from land use and from use of the runoff <u>net</u> of the costs of implementing the plan. Indices are useful in optimizing the implementation scheme, determining when plans should be adjusted to avoid costly implementation problems that encourages public compliance, and improving the efficiency of individuals charged with executing the implementation plan.

Forest Service Planning

Since the U.S. Forest Service is the major land owner in the study area, this study was coordinated with their planning so as to be able to use their data and to produce results they can apply. Forest Service planning divides the total land area into recreation units and subdivides these into ski areas, recreation highway corridors, developed hiking areas, pristine hiking areas, areas for dispersed recreation, and areas of restricted use. Areas are also classified according to whether they are open, restricted, or prohibited to mineral development, grazing, or lumbering. The classifications follow stated management objectives for an area.

Forest Service activities are structured to achieve these objectives. They define permissible uses of water, air, recreation lands, visuals, wildlife, range forage, timber, and historical and archeological sites and attempt to prevent other uses from occurring. The Forest Service also has programs for fire control, insect and disease control, and mineral development.

Management objectives in allocating land uses are:

- 1. Meet basic requirements of law, regulation, and policy.
- 2. Resolve conflicts in land use.
- 3. Establish an optimal mix of uses.
- 4. Meet public health requirements.

5. Meet economic and social needs of individuals in a manner acceptable to the general public.

6. Provide a basis for land ownership adjustments.

Gomm (1979) outlines Forest Service study plan formulation as encompassing 1) involvement of the public and all levels of government in defining management schemes and criteria for deciding among them, 2) systematic evaluation of the schemes according to the criteria chosen, and 3) implementation so as to be responsive to new issues and concerns through what is called dynamic land management planning. The process identifies tradeoffs in consequences (between big game and livestock, for example), gathers data for weighing the tradeoffs at particular locations, involves the public in their resolution, announces the management decision, and monitors response.

Suhr and Carder (1979) compare three indexing techniques for Forest Service use. The "alternative action evaluation technique" uses preassigned weights to combine factors into a composite preference index. The "pairwise comparison approach" uses pairs to rank evaluation criteria in importance, normalizes performance toward each criterion on a 0 to 1 scale, and sums the products to establish the preference index. The "trade off evaluation procedure" (McKee and Simmons 1978) ranks alternatives by developing a factor profile for each for comparing scores, criterion by criterion, and then using indifference scaling to rank the profiles. All three indices are oriented toward application by a single decision maker charged with optimization of overall forest management.

Basic Relationships

For this study, the indices were formulated from indicators that represent attributes that affect use decisions, use impacts, or use interactions. According to the adopted terminology, attributes are conceptual causal factors, indicators are numerical measurements used to quantify those attributes, and indices are used to express the combined effect of two or more indicators. Rather than using the shotgun approach of measuring many indicators and using statistical methods to search for significant associations with use, this study began by hypothesizing what a person would logically want to know when considering a given use decision, what characteristics of an area affect use impacts, and what characteristics affect use interactions. The hypothesized attributes were used to suggest indicators that could be measured. Information hypothesized as relevant could then be confirmed or refuted from correlations between the measurements and use data.

Uses result from decisions made by individuals (for themselves or as part of a management group) from information available at various levels of aggregation and interpreted from various viewpoints. For example, decisions to cut firewood are made by people combining recreation with their need for fuel and guided by land manager decisions formulating policy regulating cutting. The decisions are also influenced by opportunities for other uses perceived to be complementary (a trout stream adding to the recreation experience) or . competitive (a herd of cattle interfering with the work). The prospective firewood cutter also considers factors that influence demand for firewood (alternative fuel cost), the general destination (travel distance), and the specific location at that destination for cutting (availability of suitable trees). Management decisions try to influence users to act in compliance with such broader concerns as aesthetics, fire hazard, and national energy policy.

Information useful to each decision can be expressed by indices. To reduce the cost of planning, the decision making can be facilitated by screening out land areas in which the use is not even reasonable (firewood cutting on riparian grasslands, for example). Accordingly, the evaluation of the suitability of a given land area for a given use began by establishing a reasonability index of the form:

where IR_{ui} is a binary variable of value 1 if use u deserves further consideration in land unit i and 0 if it does not, and f_u is some rule which can be applied for determining the reasonability of use u from data on A_n easily measured indicators. Specifically, f_u converts indicators into an index. For the example application described in the next chapter, ownership, vegetation type, and locations with beetle infestation were known. The IR_{2i} (firewood cutting was use 2) were assigned a value of 1 for land units containing dead conifers on public land and 0 for other land units. Obviously, another reasonability rule would be applied in areas where a beetle infestation has not led to a policy promoting removal of dead trees.

For units whereon a use was indexed as reasonable, a use intensity index was sought with the form

where IP_{ui} is an ordinal scale becoming increasingly larger with greater amounts of the use, and g_u is some rule which can be applied for use u with data on B_{0i} indicators (combining selected A_{ni} indicators with other information whose measurement is more difficult but justified where the use will probably occur) representing attributes of the immediate land unit and C_p indicators representing attributes of a larger area round about. For this study, the C indicators are assumed to have the same value for all land units.

Since the desirability of a use depends on both user and public viewpoints, Equation 3 can be expanded to estimate the utility rather than the amount of the use giving

where IU_{ui} is an index of the overall utility of the use, V_{ui} represents the unit value of use to the user, and M_{ui} is a multiplier to adjust user value to desirability from the public viewpoint.

 M_{ui} is greater than 1 when it is in the public interest to promote a use and less than 1 when it is in the public interest to restrict the use. It was assumed for this study that V_{ui} is a scalar value with economic units and constant for all land units (i). The M_{ui} are potentially functions (h_u) of subsets of the B and C variables in Equation 3.

The B and C variables represent attributes expected to influence 1) people deciding whether and where to engage in a particular use or 2) the public attitude toward those uses. The analysis seeks to identify attributes current users consider important, measure indicators of those attributes, and combine them into indices. Measurement selection requires evaluation of how much information on an attribute is improved by greater measurement effort.

For the firewood cutting example, factors hypothesized as influencing the amount of firewood cutting within the total watershed (the C variables) were 1) a gravity model estimate of the demand of the population in the general area for firewood, 2) the profitability of firewood cutting as estimated by the price, 3) the relative advantage of using firewood as estimated by the price of alternative fuels, and 4) the competitive location of the watershed in comparison to other firewood areas with respect to population centers. The factors hypothesized as influencing where a person cuts firewood within the watershed were 1) the amount of dead wood, 2) the quality of road leading to the site, 3) access as indexed by elevation because higher lands are generally steeper and farther from good roads, 4) land ownership, and 5) owner restrictions on cutting.

Two sorts of data are required for establishing g_u (estimating IP_{ui}). One is actual use data, U_{ui} , defined as the amount of use u occurring annually in unit i normalized to a unit area basis. The other is measurements of the B and C indicators.

Derivation of g_u thus requires data on U_{ui} , B_{ki} (k from 1 to o), and C_{ℓ} (ℓ from 1 to p). Since only one watershed was examined in this study, no variation was available in the C indicators. All that could be defined was a relationship

 $IP_{ui} = g_{2u} (B_{1i} \dots B_{0i}) \dots (5)$

given the one setting defined by $C_1 \ldots C_p$. Regression provides one tool for defining g_{2u} . Approximations can be used when the amount and quality of the data do not support regression methods. Some of the preselected B_0 variables may not be significant and should be dropped. If the predictive power of the best formula is low, some definitions or measurement methods may need to be revised, or other variables may need to be added. On the other hand, a poor correlation may be simply caused by approximate use data or its inaccurate disaggregation into the i units. The C variables could not be brought into a quantitative relationship in this study because data were only available for this one watershed, a situation making it impossible to quantify variability among watersheds. With a multiple watershed data base, one could regress watershed values of use per unit area on the C variables. Whatever form they may eventually take, quantitative relationships move water and land use planning from subjective judgments to an analysis which permits simultaneous tracking of many factors from many viewpoints.

Estimation of the desirability of a use also requires consideration of the public viewpoint. Information useful in estimating M_{ui} (Equation 4) includes descriptions of current governmental efforts to promote or restrict use, attributes of a unit which influence public opinion on the desirability of that use at that location, and impacts of a use that make people feel it to be desirable or undesirable. For the example use of firewood cutting, the unit or B variables hypothesized as potentially important to the public were 1) exposure of the unit to easy view from the surrounding area and 2) the amount of dead wood as it influences both sightliness and fire hazard.

The relationship (again using h_2 as an approximation of h for the given setting)

$$M_{ui} = h_{2u} (B_{1i} \dots B_{oi}) \dots (6)$$

given C_1 C_p has both scientific and public opinion inputs. For firewood cutting, the reduction in forest fire hazard would be scientifically determined while the improvement to sightliness would be evaluated from public opinion to the gains from removing dead trees killed by bark beetles.

CHAPTER 3

DESCRIPTION AND USES OF THE UPPER BLACKFOOT WATERSHED

General Information

The Upper Blackfoot watershed selected for study lies some 60 miles east of Pocatello and 25 miles northeast of Soda Springs in Caribou County, Idaho (Figure 3). Defined as the catchment tributary to the Blackfoot River at the point where it leaves the Caribou National Forest, just below where the river flows out of a canyon called the Narrows, the study area covers 160 square miles (sq. mi.), 109 of which are within the National Forest. Ownership of the remaining area is divided among private parties (43 sq. mi.), the State of Idaho (5.5 sq. mi.), and the Bureau of Land Management (2.7 sq. mi.). Established in 1907, the Caribou National Forest covers, in several separated units, a total of 1,250 square miles.

The study area centers in Upper Valley located between two north- to northwest-trending mountain ranges. The grassed valley plains range up to several miles wide, are about 11 miles long, and geologically resulted from folding and subsequent block faulting. The Webster Range of the Rocky Mountains forms the eastern boundary, and from south to north, Dry Ridge, Wooley Range, and Grays Range border the catchment to the west. A gentle rise in the valley floor forms the northern boundary.

Catchment elevations range from almost 9,000 feet above mean sea level at several points along the ridge line of its southeastern border down to about 6,300 feet at the point where the Blackfoot River leaves the study area. Mean annual precipitation varies from about 35 inches (primarily snowfall) at the higher elevations to less than 20 inches (still largely snow) on the valley floor (U.S. Forest Service 1978).

Upper Valley is drained by two perennial streams, Lanes Creek in the northern half and Diamond Creek in the southern half. The two join to form the Blackfoot River which flows eastward through the Narrows separating Dry Ridge from the Wooley Range. The 160-square mile drainage area contains 97 miles of stream of third order or higher. Downstream from the study area, the Blackfoot River flows into the Blackfoot Reservoir (storage capacity of 237,000 acre feet) built about 1920 by the U.S. Bureau of Indian Affairs for irrigating Indian lands on the Fort Hall Reservation. Although the study area constitutes less than 28 percent of the reservoir's drainage area, it contributes most of the runoff.

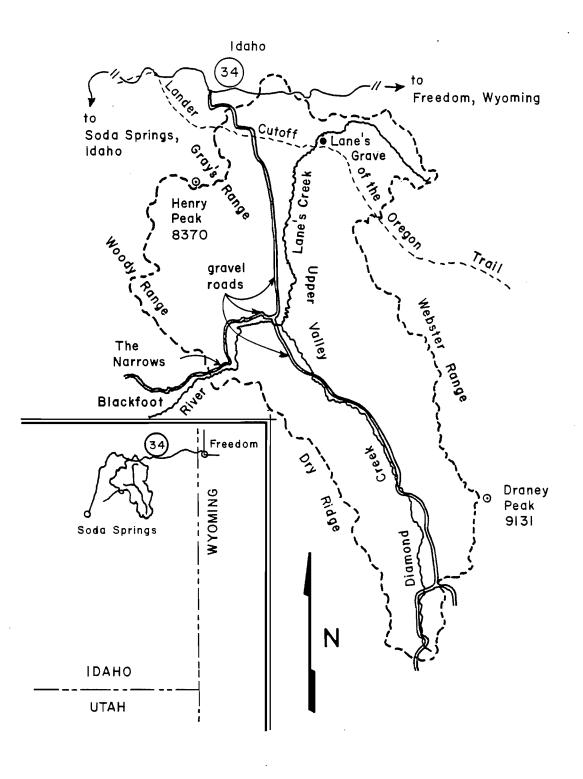

Figure 3. Location map for Upper Blackfoot River watershed.

The geologic feature of principal interest is the scattered outcrops of the Meade Peak Phosphatic Shale Member of the Phosphoria Formation, particularly on Dry Ridge where several active phosphate mines are located. The study area also lies in the western Overthrust Belt, making it the object of active oil and gas exploration. No producing wells have been drilled so far.

The Forest Service maintains gages on a number of smaller streams near the phosphate mining areas. Flow rates and several quality parameters are measured. Four U.S. Geological Survey gages are maintained on the Blackfoot River along its 80 mile course to the Snake River. Stream gage locations, tributary drainage areas, and average annual runoff amounts are listed in Table 2.

According to the Forest Service's classification based on morphology and soils, 40 land types in 10 major groupings are found in the study area (Table 3). Each land type was rated by the Forest Service according to its susceptibilities to erosion and mass failure (landslides) and productivities for range and timber.

The vegetation varies with elevation, moisture, aspect, and soil. The six principal types of cover are conifer (primarily Douglas Fir and Lodgepole Pine), aspen, mountain brush, sagebrush and grass, riparian grass, and riparian willows. The forests are located primarily at higher elevations on north and east facing slopes. The dry, cold climate is less than ideal for commercial timber regeneration but sufficient to support a moderate harvest program. Recently, a bark beetle infestation has damaged mature stands, and the dead trees are being harvested for firewood.

A 1977 environmental impact statement (U.S. Department of the Interior 1977) identified 75 species of mammals, 272 species of birds, 13 species of reptiles, 6 species of amphibians, and 9 species of fish in the Caribou National Forest. Since the Upper Blackfoot drainage contains only about 8 percent of the forest area, fewer species would be expected in the study area. Game species include deer, elk, partridge, grouse, ducks, rabbits, and cutthroat trout. No endangered species are known to reside in the area.

The nearest population center is Soda Springs, Idaho, established in the 1860s to secure a popular Oregon Trail rest stop from Indians (Bureau of Land Management 1978). Agriculture and phosphate ore processing now provide the major commercial support for its 4,500 residents.

Idaho Highway 34 from Soda Springs to Afton, Wyoming, passes through the northern tip of the unit and is the only paved road in the area. Because it is a more direct route from the Idaho population centers, however, the primary access to Upper Valley is by a gravel road entering through the Narrows from the west, following the Blackfoot River, and branching north and south in Upper Valley with the forks following Lanes and Diamond Creeks, respectively. Numerous dirt roads connect to this gravel road and provide access to mountain

areas on both sides of the valley for mining, logging, grazing, and recreation.

The first mining activity in the region was for gold, found in 1870 near Caribou Mountain, several miles north of the study unit. The Phosphoria Formation outcrops were discovered in northern Utah in 1889, but the deposits were too remote from the central states fertilizer market, and the fields were slow to develop. In 1908 and 1909, reacting to acquisition and mining for export by European interests of major Tennessee phosphate deposits, the Secretary of Interior reserved to the United States all the potentially valuable phosphate deposits on federal, state, and private lands in southeastern Idaho, northern Utah, and southwestern Wyoming (Bureau of Land Management 1978). These mineral rights were subsequently placed under a leasing program (by the Mineral Lease Act of 1920) that continues to the present (30 U.S.C. 181). Two significant mines opened prior to World War II, but virtually all current leases were issued after 1948.

Most of the oil and gas rights are also federally controlled, but both sites where exploratory drilling has occurred have been on state lands. The establishment of the Caribou National Forest similarly placed most of the area's timber resources under federal management. The main activity of the private landowners is livestock grazing, using their valley lands as summer range for cattle and sheep. Most of the public land is divided into cattle or sheep allotments, although few of the private landowners hold permits.

Hydrogeologic Data

The major geologic formations in the study area, as reported by Montgomery and Cheney (1967, p. 5), are the Monroe Canyon Limestone (Mississippian Series), Wells Formation (Pennsylvanian Series and Permian Series), Park City and Phosphoria Formations (Permian Series), Dinwoody, Woodside, and Thaynes Formations (Triassic System), and alluvial and colluvial deposits (Quarternary System). The Dinwoody and Wells Formations, along with unconsolidated deposits of colluvium and alluvium, are the most important aquifers (Cannon 1979, p. 39). The geologic and hydrogeologic characteristics of these geological units are described in Table 4 (modified from Ralston and Williams 1979, p. 243). The low permeability of the Phosphoria Formation divides the groundwater into two systems (Dinwoody Wells above and below the Phosphoria Formation). Flows may occur between the aquifers through fractures.

The lithology of these formations (primarily limestone, siltstone, and phosphatic rock) suggests that groundwater discharging from them would have high concentrations of calcium carbonate, phosphate, and a pH greater than 7.0. This is typically the case.

Formation/		Thickness		Hydrogeologic characteristics

Climatological Data

Temperatures at valley floor elevations range from -40° to 90° F. Mean monthly temperature for July is 58°, and for January, 12°. The growing season varies from 105 days at 6,500 feet to 15 days at 8,500 feet. The mean elevation is about 7,250 feet, and the average growing season is 49 days. The short growing season restricts ranching to summertime grazing by cattle and sheep.

Snow begins falling at higher elevations by October. Prevailing winds from the southwest cause snow to accumulate on the north and east sides of ridges. Drifts sometimes exceed 30 feet in depth and 6 miles in length. By March, snow depth varies from a few inches on the windblown, south- and west-facing ridgetops, to 6 feet or more in some valley bottoms and northeast-facing slopes. Spring snowmelt begins at the lower elevations and proceeds more rapidly up the south and west facing slopes with their greater exposure to the sun. The peak runoff occurs from mid-April to late May.

Table 5 shows available temperature and precipitation data for recent water years for Afton, Wyoming, and Conda, Grace and Henry, Idaho. No regular measurements are made in the study area. The water year 1977 was characterized by a drought that was actually more severe than indicated by the table because much of the precipitation fell in summer storms generating little runoff.

The vegetation shows that precipitation increases with altitude but measured data are not available for higher elevations. On an average, the temperature decreases as altitude increases. The rate of decrease vertically (the lapse rate) averages about 3.8°F per 1000 feet (Linsley et al. 1975). Better information on how both precipitation and temperature change with elevation would be useful in developing models to predict runoff.

Cloudy weather prevails throughout the winter with measurable precipitation (snow) about one day out of three. Snow course data are available for four stations located near the study area. Summer precipitation is mostly in local, intense thunderstorms.

Relative humidity is lower in summer than in the winter, and in afternoon than in morning. July and August have the lowest monthly averages of 40 percent. Annual mean relative humidity is 62 percent (U.S. Department of Commerce 1976).

A four-foot stainless steel evaporation pan is located at Lifton Pumping Station, Idaho (elevation 5275 ft) south of the study area. Evaporation is measured at this station during the growing season. Data show the highest evaporation during July (Table 6 from National Oceanic and Atmospheric Administration (NOAA) 1975, 1976, 1977, 1978, 1979).

Land and Water Uses

Selection

A use was defined as an activity utilizing a land unit or the waters of a stream reach. A use was selected for analysis if 1) significant amounts are now occurring (determined through consultation with people familiar with the area), 2) it has distinctive land or water requirements not automatically accommodated in providing for other uses in the selected set, and 3) it has sufficient interaction with other uses to require that the interaction be analyzed to determine the best overall combination of uses. By way of illustrating the second and third criteria, use of the study area by many small animals and birds was not analyzed because a) their needs are automatically met by providing timber and habitat for big game and b) they are not known to compete with other uses.

Application of these criteria assumed that major use changes will not occur in the period of analysis. Where doubts exist, the area could be monitored for major use changes that could require adding or deleting uses from the set being analyzed and repeating the study. For example, one should watch for rare species with localized habitat that might be harmed by a land use change over a small area. New commercial or recreational demands can also develop. The likelihood of use additions or deletions occurring in the Upper Blackfoot River catchment in the next few years was considered too remote to warrant further attention.

The 17 land uses and the 4 water uses selected according to the above criteria for analysis of the Blackfoot River watershed are listed in Table 7. They are classified according to 1) the locus of decision making on the amount, type, and location of the use, 2) the general goals for engaging in the use, and 3) according to whether the use is amenable to incorporation in the management model developed in this study.

As to locus of decision making, the centers were classified into three groups:

- C. Centrally managed uses, generally undertaken after a somewhat objective analysis by some formal decision group such as corporate management and with which planners can interact directly in minimizing conflict between private development objectives and the public interest. These uses can be subdivided between those which occur occasionally (CO) and those which become relatively permanent on a selected land area (CP).
- D. Dispersely selected uses, chosen by individuals widely scattered in place and time, such as recreationists. These uses can be modified by governmental incentives or regulatory action, but the degree of control is much less than that for centrally managed uses.

		Decision Centerl	General Goal2	100 0 4
	Land Uses			
1.	Commercial logging	CO	Е	+
2.	Firewood cutting	D	RE	+
3.	Phosphate mining	CP	E	
4.	Oil and gas exploration	CO	E	
5.	Cattle grazing	CO	Е	+
6.	Sheep grazing	CO	Е	+
7.	Deer habitat	N .		+
8.	Elk habitat	N		+
9.	Moose habitat	N		+
10.	Hunting	D	RE	+
11.	Hiking - dispersed camping	D	RN	+
12.	Concentrated camping	CP	RN	+
13.	Roads	CP	E	+
	Snowmobiling	D	RE	+
	Summer off-road vehicle use	D	RE	+
	Buildings	CP	E	-462
17.	Archaeologic & historical resource	s CP	RN	
	Water Uses			
W1	Fish habitat	N		· +
W2	Fishing	D	RN	+
W3	Runoff for downstream use	N		· +
W4	Quality of runoff	N		+

Table 7. Land and water uses defined and classified for analysis.

lCO = centrally managed, occasional use; CP = centrally managed
permaanent use; D = dispersely selected use; N = natural use.

 ^{2}E = primarily economic goal; RE = high energy recreational use; RN = low energy recreational use.

N. Natural uses, resulting from physical or ecological processes. Here, the planning role is largely one of protecting process productivity from undue interference by the first two classes of uses. Natural process productivity is primarily achieved through maintaining good habitat for fish or wildlife and by a watershed with good yield of high quality runoff.

As to the user goals for the centrally managed and dispersely selected use, they generally divide between being primarily economic (E) and primarily environmental (R). The designation R is used because the environmental values are primarily enjoyed recreationally. These recreational uses can be further subdivided to low energy uses that blend into the natural environment (RN) and high energy uses that tend to be more disruptive (RE).

The decision to incorporate a use into the planning model was based on whether the amount of use was primarily determined by factors within the scope of this analysis. A negative classification meant that the amount of the use was judged as determined by exogenous considerations.

Measurement

Land and water use measurement requires definition of what is to be measured, units of measurement, and a procedure for making the estimates. The definition concepts, use units, and estimation procedures followed in this study are presented below for each of the 21 uses on Table 7. Figure 4 provides photographs showing selected uses. The year 1980 was selected for the measurements as a recent year for which data were available and conditions were about average.

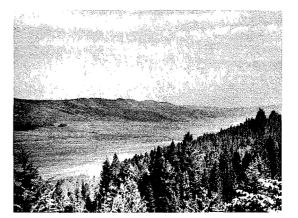

- 1. Commercial Logging
 - Concept: Logs are harvested for commercial profit. Three concepts must be considered in measuring use of an area for commercial timber production, a) currently harvestable timber, b) long term average annual yield, and c) timber actually being harvested. Burt and Cummings (1977) explore long-run equilibrium and the socially optimal rate of utilization as alternative management policies. The actual harvest determines the income of the loggers and the interactions with the other uses. The currently harvestable timber sets an upper limit to what can be cut this year, and the long term yield sets a lesser upper limit to what can be cut on a sustained basis. Actual harvest is currently less than sustained yield, and harvest data are more easily obtained than are yield data. Logging was thus measured in harvest units for both theoretical and practical reasons.

Units: Board feet (ft² x in) of lumber harvested.

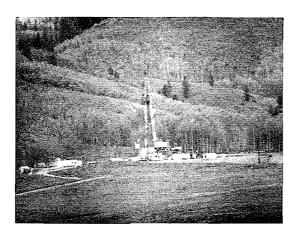

Estimating Total Amount: Harvest data obtained from the Forest Service are in Table 8. Severe logging occurred in the 1950s; and from then to 1972 very little timber was cut except for posts and poles. Annual harvest (reported by designated sale areas comprising several cutting sites) from Forest Service land since 1973 has averaged about 2,500 MBF. Some additional timber has been harvested from non-Forest Service lands, but amounts are small because most timber of commercial

quality is in the National Forest. Harvest locations are varied from year to year under the general guidance of a five-year plan. Mining activities and fluctuations in lumber prices cause variations from the uniform annual cutting rates suggested by the plan.

- 2. Firewood Cutting
 - Concept: Firewood cutting is done both as a recreational activity and for the value of the wood. The firewood is largely cut on National Forest land from conifers killed by bark beetle or other infestations. Lesser amounts come from timber sale slash piles. The current annual harvest is far below the death rate for the trees, and was employed to define use for the same reasons presented above for commercial logging.

Units: Cords (128 ft³) of firewood cut.

- Estimating Total Amount: Forest Service data on permits granted to households by the Soda Springs District within the past several years were used to estimate the amount of firewood being taken from the study area annually. Personnel there estimated that 75 to 80 percent of total permits were for firewood cutting in the study area. Their knowledge of the area was also used in estimating wood taken without permit on Forest Service lands or on Bureau of Land Management, state, and private lands where permits are not required. Resulting figures are in Table 9.
- 3. Phosphate Mining
 - Concept: Phosphate ore is mined and hauled out of the study area for processing. With current mining costs and phosphate prices, the operation is commercially profitable for ore bodies with a P205 content exceeding 20 percent and a stripping ratio (depth of overburden to ore thickness) less than 3. A number of such locations have been identified. Mine development responds to rising prices on the world phosphate market and requires establishment of access, site preparation, setting up the mining equipment, and making ore processing arrangements. Site selection depends on development cost, stripping cost, and ore quality. These factors (except for relatively minor interactions with other uses that affect development and stripping costs) are largely exogenous to this study.

Units: Tons of ore.

Estimating Total Amount: The environmental impact statement (EIS) (U. S. Department of the Interior 1977) maps potentially profitable locations to mine, provides descriptive information on the sites, and projects

Year	Number of Permits	Basis	Amount of W (cords)	ood taker (MBF)
1977		free	1627	2,50
1978	1,275	free	2075	3,188
1979	1,885	free	2944	4,524
1980	1,000	free	1621	2,49
	1,621	fee	1842	2,83

Table 9. Estimated firewood cutting.

future production rates. These production rates were used even though recent weakness in the world economy has caused production rates to lag EIS expectations.

- 4. Oil and Gas Exploration
 - Concept: While oil or gas has not been found in sufficient amounts to justify commercial production in the study area, a promising location in the Overthrust Belt continues to prompt exploratory drilling.

Units: Holes as a 0-1 binary variable.

Estimating Total Amount: Two wells were drilled in the study area during 1980. The Idaho Division of State Lands provided sufficient description of the two locations to identify specific land units. Neither well was located on federal land.

5. Cattle Grazing

- Concept: Beef cattle are brought into the area to forage for summer feed on both public and private land. Permits, specifying number of animals, time period, and location, are required for grazing on public lands and seem to be holding grazing amounts well within the limits of forage productivity. Private landowners spread stream flows during spring snowmelt periods over the meadowlands in Upper Valley for increased forage growth, but hay is not cut. Following the principles presented above for logging, the food eaten by the cattle was taken as the measure of use.
- Units: Annual cattle animal-unit-months. One AUM equals 720 lbs. of feed.

- Estimating Total Amount: The Forest Service and Bureau of Land Management supplied estimates of the number of animals, gross cattle AUMs on their land, and maps of areas where cattle are allowed to graze. Private land owners were asked their herd size and to estimate grazing AUMs in their fields.
- 6. Sheep Grazing
 - Concept: Shepherds bring sheep into the study area for summer pasture on Forest Service land reserved for them by the grazing permit system. The food eaten by these sheep was taken as a reasonable measure of use.
 - Units: Annual sheep animal-unit-months. One sheep AUM equals 0.2 cattle AUM or 144 lbs of feed.
 - Estimating Total Amount: The Forest Service and Bureau of Land Management supplied estimates of the number of animals, gross sheep AUMs, and maps of areas where sheep grazing is permitted. The Forest Service also supplied information on landowners with flocks.

7. Deer Habitat

- Concept: A number of methodologies have been proposed for assessing wildlife habitat (Whitaker and McCuen 1976; Hawes and Hudson 1976). Deer browse primarily on hardwood twigs. Heavy snows bury twigs, restrict animal movement, and hence force deer to feed at lower elevations. This situation would suggest winter food availability to limit the number of deer that an area can support, however, during most winters deer are forced entirely out of the study area to lower elevations (Kuck 1979). For this reason and to have a better basis for defining tradeoffs between livestock and native animals, the ability of the study area to support deer was also estimated in units of forage eaten. This choice also facilitates use of the Idaho inventory data on the availability of habitat defined by species preferences for vegetation and elevation.
- Units: Annual deer animal-unit-months. One deer AUM equals 0.25 cattle AUM or 180 lbs of feed.
- Estimating Total Amount: Data from Forest Service deer surveys for the Idaho Fish and Game study area (about six times the size of the area covered in this study) are shown on Table 10. These data on numbers of deer at various elevations and in various cover types provide a basis for estimating relative numbers of deer in the watershed by season. These estimates can then be summed over the year to estimate annual AUMs.

,

.

- 8. Elk Habitat
 - Concept: Elk, like deer, feed on hardwood twigs and are largely forced out of the study area in winter. Consequently, the measurement method described above for deer was used again.
 - Units: Number of elk AUMs. One elk AUM equals two thirds of a cattle AUM or 480 lbs of feed.

Estimating Total Amount: The elk data on Table 10 were used in the same manner as that described above for deer.

- 9. Moose Habitat
 - Concept: Moose concentrate in riparian shrub areas and are also forced to lower elevations by deep winter snows. Hence, the measurement principle of food consumed was again used.
 - Units: Number of moose AUMs. One moose AUM is the same as a cattle AUM or 720 lbs of feed.
 - Estimating Total Amount: The moose data on Table 10 were again applied in the same manner as those for the other big game species.

10. Hunting

- Concept: Nielsen and Catton (1971) proposed an information retrieval system for organizing information on the relevant literature on the sociological determinants of forest recreation. For example, hunters seek deer, elk, and small bird and game species, partly for food but, as assumed for this study, primarily for recreation. The recreational value of hunting varies among species (Holbrook 1970) as seen by the fact that hunters go much further for rare or exotic species. In principle, species hunted should be differentiated during data collection; however, in the Upper Blackfoot Area, deer and elk hunting so dominate the activity that the effort is not justified.
- Units: Hunter-days defined as days any part of which is spent in hunting.
- Estimating Total Amount: The Forest Service estimates that 3,910 user days of hunting occurred in the watershed in 1980 and that this number will increase to 5,865 by 1990 (Table 8). The agency also indicates that over 75 percent of the hunting takes place in the Diamond Creek portion of the study area and about two thirds of that use occurs on the east side of the creek.

11. Hiking - Dispersed Camping

- Concept: Many people visit a remote area to observe nature or be alone. They walk or camp in secluded spots for the recreation experience and to enjoy the scenic beauty (Arthur and Roster 1976). Hikers follow roads, walk along trails, or (in the low intensity situation of the Upper Blackfoot) go across country and leave defined paths for their recreation experience. Winter travel may be by skiing. Backpackers and people traveling by horse or by motor vehicle may camp overnight along their route. The campers who spend their nights outside developed campgrounds typically follow side roads along tributary streams to sites that afford adequate firewood and privacy. Hikers and cross country skiers can follow roads, walk along trails, or go across country. The study area has a fairly extensive network of trails, probably livestock routes, even though trail development and maintenance has been miminal except on the Lander Cutoff of the Oregon Trail. The Forest Service now has a trail development and management plan. The most likely hiking routes are along established trails and low grade roads.
- Units: Hiker-days, defined as days any part of which is spent in traveling by foot, except as incidental to the other defined uses for this study, or as nights spent outside designated campground areas.
- Estimating Total Amount: The Forest Service estimated 700 hiker days in 1980 and projected an increase to 1,050 hiking days in 1990. Dispersed camping was estimated at 7,000 user days in 1980 to increase to 10,500 in 1990.
- 12. Concentrated Camping:
 - Concept: Two campgrounds have been established in the study area. The Mill Creek site is located at the upstream end of the Narrows, and the Diamond Creek site is about 15 miles further upstream on Diamond Creek. The Forest Service has no plans for expanding developed camping facilities. Frissell and Duncan (1965) characterize campsite deterioration and propose a methodology for estimating campsite durability.
 - Units: Camper-days defined as nights spent in the designated campground area. In contrast to the other recreation activities, camping is constrained by campground capacity. Bultena and Klessig (1969) discuss the values people seek in camping. Capacity can be measured in campsites per campground or the maximum number of persons that can be accommodated at one time (PAOT).

- Estimating Total Amount: The Mill Canyon campground has 10 campsites and a maximum PAOT of 65. The Forest Service estimated total camper-days in 1975 at 6,600 and in 1980 at 7,600. The Diamond Creek site does not have individually designated campsites and occupies a slightly larger area. The Forest Service specifies its maximum PAOT at 100. Use in 1975 was estimated at 3,800 and at 2,600 in 1980. Demand at both sites is forecast to increase at about 5 percent annually.
- 13. Roads
 - Concept: Roads provide the routes for traveling to preferred use areas. A route was classified as a road if it was judged to be passable with a four-wheel drive vehicle during summer periods after the snow is melted and no rain has fallen for at least 24 hours.
 - Units: Roads were measured in miles and classified according to quality. Road quality categories were paved, gravel, dirt and passable by ordinary vehicle, and dirt and passable only by four wheel drive vehicle. The highest class of road in a unit was also recorded.
 - Estimating Total Amount: The information on roads was gathered from Forest Service maps as supplemented by site inspections.
- 14. Snowmobiling
 - Concept: Snowmobiling in the area is predominantly recreational, and it was considered exclusively so for this analysis. Snowmobilers often follow roads or trails but also travel across country in areas without heavy forestation.
 - Units: Snowmobiling-days, defined as days any part of which is spent snowmobiling.
 - Estimating Total Amount: About half of the snowmobiling estimated to be taking place in the Soda Springs District (Table 8) is believed to occur in the study area. In 1980 the amount was estimated at 1,650 user days (projected to increase to 2,475 user days by 1990) on roads (350 user days), trails (400 user days), and open areas (900 user days).
- 15. Summer Off Road Vehicles (ORVs)
 - Concept: Many people enjoy driving in remote areas for recreation. Others drive for monitoring livestock or tending other commercial uses. Both two and four-wheel ORVs are used.
 - Units: User days, defined as days any part of which is spent touring in ORVs.

- Estimating Total Amount: The 1980 ORV use was estimated at 2,000 user days and projected to increase to about 3,000 by 1990.
- 16. Buildings
 - Concept: Buildings were defined as fixed residential structures, and thus excluded mining sheds, corrals, and other such structures. Movable house trailers and other temporary residential structures that do not stay long at any one site were also excluded.
 - Units: Counted buildings.
 - Estimating Total Amount: Twelve buildings were identified from maps, aerial photos, field inspections, and conversations with Forest Service personnel. There is little likelihood of more building in the near future. Forest Service personnel are not issuing special use permits for residential structures, and building on private lands is restricted due to poor drainage for septic tanks (Southeast Idaho Council of Governments 1977). Existing residences are only seasonally occupied since the entire area is often inaccessible in winter. In the summer, several dozen mobile homes and motorized campers are moved into the area and used by recreationists or miners, herders, or lumberjacks working nearby.
- 17. Archaeological or Historical Sites
 - Concept: Many types of archaeologic, historic, geologic, or other sites of special value were sought and evaluated but only the route of the Lander Cutoff of the old Oregon Trail and Lane's Grave were identified as significant.

Units: Number of identified sites.

Estimating Total Amount: Lander Cutoff is named after Frederick W. Lander, a Department of Interior employee sent in 1857 to survey an alternate route to the Oregon Trail from South Pass, Wyoming, to Fort Hall, Idaho. The alternate route was needed because heavy use on the Trail had depleted forage along the way. The cutoff traverses the north portion of the study area, before joining Idaho Highway 34. Portions of the original road are still discernible, and the Forest Service has fenced off two short stretches. Lane's Grave is found in the north part of the study area, near where the Lander Cutoff crosses Lane's Creek. The fenced gravesite contains three graves in a row. The two outer graves are unmarked, but a headstone marking the center grave bears the inscription: J. W. Lane, Died July 18, 1859 AD-50 yrs 2 mos. The story behind the three graves remains a mystery.

Wl. Fish Habitat

- Concept: Streams vary considerably in the amount and type of fishery they support. All of the third order and larger streams identified for this study are large enough to support fish. Thurow (1980) listed 13 species of fish present in the Blackfoot River drainage. The drainage has historically supported a high-quality cutthroat trout fishery, and trout needs were used for defining habitat quality. Habitat can be indexed empirically from numbers of observed fish or theoretically by comparing stream characteristics to known species needs. Actual data on fish locations are needed to verify fish habitat preferences, and habitat characteristics are the factors directly affected by land and water use.
- Units: Fish habitat was quantified by a habitat quality index.
- Estimating Total Amount: The Idaho Department of Fish and Game (Thurow 1980) began a three year study of the fish in the Blackfoot River drainage in 1978 and took a fish census. For this study, habitat quality was measured by an index developed from five characteristics observed for each land unit containing or bordered by a third or higher order stream. Cutthrout trout need dependable flow, pools, cobbles in the stream bed and vegetative cover on the stream banks. They are harmed as sediment clogs their environment. Consequently:

Fish habitat = FLOW * POOL-RIFFLE * SUBSTRATE

* COVER * STREAM MILES/(3.5 * SEDIMENTATION)

. (7)

where flow was crudely estimated in terms of adequacy to support an adult fish; the pool-riffle ratio was an index on the amount of pool in the stream and was taken as reaching a maximum value (1.0) at 45 percent pool; the substrate rating ranged from 1 to 4 for silt to cobble; cover was the percent of streambank under vegetative cover; the sedimentation rating ranged from 1 to 3 with increasing sedimentation; and stream miles was the length of third and higher order streams within or bordering on a unit.

W2. Fishing

- Concept: Recreationists can pursue a wide variety of stream life forms. In the Upper Blackfoot drainage, the activity is limited to trout fishing.
- Units: Angler days, defined as days any part of which is spent fishing.

- Estimating Total Amount: Thurow (1980) estimated 1999 angler days in the area during the 1978 season. The Forest Service estimated 1980 use at 2,000 angler days, projected to increase to 3,000 by 1990. Thurow's figures are broken down by reach in Table 11.
- W3. Runoff
 - Concept: Runoff volumes increase with the greater precipitation and lower evaporation rates generally associated with higher elevations. They are also increased by reductions in consumptive use by vegetation. Reduced vegetation also favors earlier spring snowmelt. Flows from the basin are stored in Blackfoot Reservoir for irrigation use. The extra runoff flows downstream through a series of reservoirs on the Snake and Columbia Rivers to the Pacific Ocean and has a large economic value from the hydroelectric power generated on the way (Hastay et al. 1971).

Units: Acre-feet/acre.

- Estimating Total Amount: The average annual runoff from the study area is gaged (Table 2) as 111,500 acre-feet or 13.0 inches over the area. Runoff varies considerably from year to year. At the Henry gaging station above the Blackfoot Reservoir, it ranged from a low of 51,810 acre-feet in 1977 to a high of 179,600 acre-feet in 1971.
- W4. Water Quality
 - Concept: Water quality evaluation depends on the uses to be made of the water. In the context of a wildland watershed, water quality is determined by variables affecting instream uses including fish habitat, aesthetic and recreational values, and downstream uses such as potable water supplies, irrigation, and reservoir renewal. The parameters best used to measure quality vary with needs from site to site.
 - Units: Nondimensional indices constructed to represent the severity of the adverse effect caused by a given degradation in water quality.
 - Estimating Total Amounts: Records of measured water quality parameters were obtained for 13 sampling sites in or near the study area. Additional samples were collected and analyzed by project personnel. By using the collected data, two indexing approaches were tried. Mahmood (1981) and Mahmood and Messer (1982) describe their effort of combining the available data statistically to retain as much content as possible in a water quality index. The second approach was to construct indices known to be

Stream	Angler Days (1978)
Blackfoot River Section 5 Section 6 Diamond Creek	779 246 651
Lanes Creek Sheep Creek Spring Creek	137 80 60
Misc. Tributaries	46

Table 11. Angler census by stream reach.

affected by existing land uses and detrimental to existing water uses. The indices constructed were concentrations of phosphorus and nitrogen (because of their known contribution to eutrophication of downstream reservoirs) and sediment load (because of the adverse impact of sediment on fish habitat).

CHAPTER 4

PATTERNS OF CHARACTERISTICS AND USES

WITHIN THE STUDY AREA

Introduction

The previous chapter described the Upper Blackfoot Watershed and the uses made of the area. Obviously, neither the physical characteristics nor the uses are uniformly distributed over the area as a whole but rather the many characteristics and many uses are each distributed in their own unique pattern. The topic of this chapter is measurement of those patterns so that relationships among them can be established for planning applications (Equation 5).

The spatial characterization of a watershed requires decisions on the detail to use, the measurement grid (from uniform squares to areas contained within irregularly shaped boundaries), and the physical characteristics and uses to measure. For planning, these decisions cannot be finalized ahead of time but rather should be approached iteratively balancing measurement effort against results obtained. Within this trial-and-error process, however, it is much easier to start with small and reasonably homogeneous units and then aggregate into larger ones as the original detail is found not to be needed, than to start with larger and more diverse units only to find them too coarse and be required to return to the field to make more refined measurements.

Delineation of Study Units

Economic development planning requires units at least as large as counties. Environmental analysis must consider much smaller units because topography, soils, vegetation, and the ecologic system they support vary greatly over short distances and control the environmental impact of a given use and thus the public interest in regulating that use. Individual users, whether considering sites for major investment in land development or an hour of recreation, examine specific locations. Sometimes their choice is based on such local site specific conditions as views or trees, but as long as the sites being compared are within an environmentally homogeneous area, the public interest would be indifferent. The size of study units selected to define spatial patterns for the Upper Blackfoot River was the smallest found to be homogeneous with respect to key environmental factors.

For this study, the principle of land unit delineation by environmental homogeneity was applied by using Forest Service mapping of areas homogeneous according to the definitions outlined on Table 3. These definitions essentially developed out of Forest Service experience as to the maximum spatial resolution useful to them as land managers. Specific descriptions of how the total study area was subdivided follow.

- Water Planning Units Runoff and water quality are determined by the size and physical characteristics of the tributary watershed. Therefore, the total Upper Blackfoot watershed was first subdivided along drainage boundaries. Each resulting water planning unit contains a reach of stream and the watershed area directly tributary to that reach.
 - Reach of stream. Because research suggests that streams a. smaller than third order are not able to support fish, only streams of third or higher order were identified. This was done from the Forest Service map of the Caribou National Forest (scale: 0.5 inch = 1 mile) as shown on Figure 5. The total stream length of 97 miles was subdivided among 38 reaches, where a reach is defined by junctions of streams of second or higher order. Boundaries based on these junctions were modified, however, for some streams of higher order. Two (water planning units) of the ten fourth order reaches drained such small areas that they were assigned to an adjacent upstream or downstream reach (leaving 36 reaches). The areas draining directly into fifth or sixth order streams were relatively long and heterogeneous. It was decided to subdivide them along drainage divides between second order tributary streams. An additional 19 reaches were thus identified. The resulting 55 stream reaches varied in length from about 1/8 mile to over 4 miles.
 - b. Tributary watershed area. Tributary watershed boundaries were drawn to show the areas contributing flow to each of these 55 reaches. These boundaries are shown by the dashed lines on Figure 6.
- Land Planning Units The water planning units were further subdivided based on Forest Service land types defined by physiographic and topographic features and (in some cases) predominant vegetative type. The 40 land types found in the study area are shown in Table 3. The mapping of these units within the National Forest was done by the Forest Service. Their procedures were duplicated as closely as possible in mapping lands outside the National Forest.

A land planning unit was defined as a contiguous area of a given land type entirely within a given watershed planning unit. An area less than 40 acres was combined with the adjoining unit in the same watershed of most similar land type. A total of 343 land planning units were defined as shown on Figure 6.

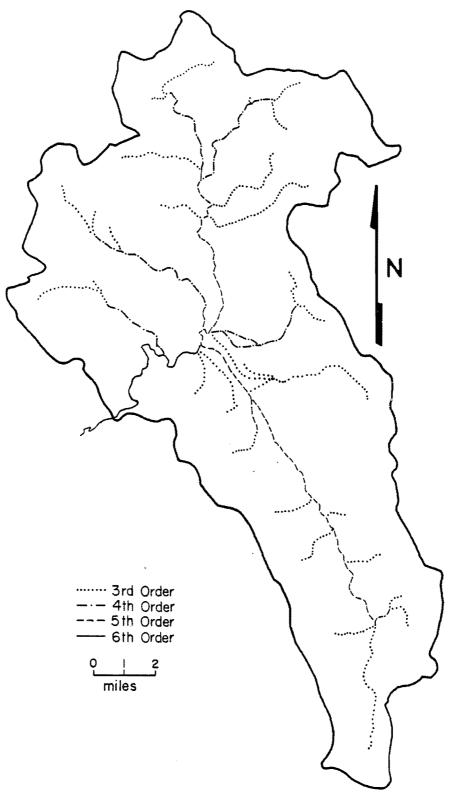

Figure 5. Third and higher order streams in the Upper Blackfoot drainage.

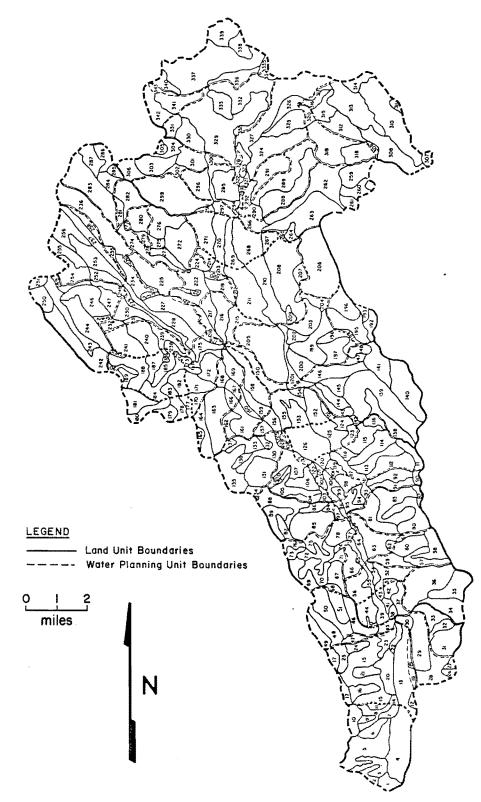

Figure 6. Land units in the Upper Blackfoot watershed.

Spatial Patterns of Physical Characteristics

Portrayal of the spatial patterns of the physical characteristics of the study area required definition of the attributes to be measured and then measurement of indicators of those attributes for the 343 land units. Attributes were considered for measurement if they were believed useful for estimating 1) the probability a centrally managed use will be undertaken, 2) the amount of dispersed use to expect, 3) population densities of fish or wildlife, 4) the desirability from the public viewpoint of promoting or denying specific uses, or 5) the magnitude of the interaction among pairs of uses.

Specific attributes were hypothesized from theoretical constructs or empirical relationships. Measurement methods were selected through interaction with users and managers. The process sought attributes:

1. Related to a use, impact, or interaction. An attribute may be useful in selecting a use or affect how people feel about use by others.

2. Amenable to measurement. Alternate measurement methods can be used for estimating the magnitude of a given indicator, and the information gained by more precise and costly measurement needs to be examined to determine whether the extra effort is worthwhile. Also, indicators may either be measured directly or be represented by easier-to-measure surrogates. For example, in an area where winter snow depth increases with elevation, elevation might be tried as a surrogate indicator of snow depth.

An attribute may be measured as a single number or as a vector of two or more numbers. Because the same indicator may be used in formulating two or more indices or as surrogates for different attributes, the total number to be measured (for which measurements can be afforded) is generally fewer than the number of indices needed for land and water planning. Furthermore, the logic for using a given attribute may vary greatly among indices.

The first step in composing a list of attributes was to enumerate land unit characteristics that should logically be included in relationships for estimating or evaluating land or water uses, impacts, or interactions. Measurement methods were then specified for each proposed characteristic. Similar measurements can be compromised in a single indicator meeting multiple needs in the interest of study economy. The resulting list was then classified between two groups according to ease of measurement with the idea that the second group need only be measured should the set of attributes in the first group suggest that they will be needed.

The 18 site attributes considered for establishing indices of reasonability (Equation 2) for the 21 uses (Table 7) are presented in Table 12. The 37 data items (with extra items for multidimensional indicators) measured are listed in Table 13. The measurements for the 37 items for each of the 343 units are recorded in Table 14.

Table 12. Definition of attributes for reasonability indexing (Equation 2).

~~~~ģ

| ndicator | Attribute, measurement method for indicator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A1       | Land area, square miles planimetered from a working map<br>of a scale of 1 inch = 1 mile. The conversion from the<br>planimeter reading to area required division by a conver-<br>sion factor of 0.106, which was performed by computer.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Α2       | Land classification, numbered 1 to 40 as defined by Table<br>2 and indicated on Forest Service maps. The Forest<br>Service land classification system was extended to<br>non-Forest Service lands by using a steroscopic viewer to<br>examine aerial photographs to compare visible surface<br>features with those on land units already classified by<br>the Forest Service or features named in the classifica-<br>tion system. Relevant surface features included land<br>contours, aspect, vegetation, and moisture (wet areas are<br>darker). Most of the units so identified were in the<br>valley bottom lands and wet or dry alluvial. |
| A3       | Vegetation type, tenths of the area in conifer (subdivid-<br>ed between commercial and noncommercial timber), aspen,<br>mountain shrubs, sagebrush and grass, riparian grass, or<br>riparian willow (not recorded but equaling the residual)<br>respectively as estimated using the Forest Service<br>classification and map (1 inch = 1/2 mile). The coverage<br>was extended to nonforest land using black and white<br>aerial photos supplemented by some unsystematic, spot<br>ground checking.                                                                                                                                            |
| A4       | Land ownership, fifths of the area as determined by<br>transferring a BLM land ownership map to the working map<br>showing land units. Ownership was classified as USFS,<br>other public (including BLM and state) or private.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| А5       | Road type, classified according to the quality of the<br>road surface into paved, gravel, dirt 1, dirt 2, and<br>none (assigned values 4 through 0, respectively). Unit<br>is coded with the highest quality road found within it or<br>the Forest map. Road conditions were largely confirmed<br>by observation. The first three road types are generally<br>usable by passenger vehicles when dry.                                                                                                                                                                                                                                           |
| A6       | Road length, miles of mapped roads in unit as measured by digitizer to nearest 1/10 mile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| А7       | Road distance, in miles, of shortest route (using only<br>roads of an equal or higher quality) from unit to Narrows<br>using digitizer on the Forest map. Most visitors to<br>the watershed enter by this route, and the attribute thus<br>measures travel distance to population centers.                                                                                                                                                                                                                                                                                                                                                     |
|          | 54                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Indicator | Attribute, measurement method for indicator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A8        | Stream length, of third order or higher within (or<br>bounding) a unit, in miles as measured, using the digiti-<br>zer on the Forest map.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| A9        | Stream order, the highest order in a unit, as deter-<br>mined on the Forest map (third order or higher).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| A10       | <u>Stream slope</u> , approximated by calculating stream slope by<br>subtracting unit minimum (Al6) from maximum stream<br>elevation (Al8) and dividing by stream length (A7).<br>(Units containing third or higher order streams only.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| All       | <u>Tributary area</u> , estimated from planimetered tributary<br>drainage area at lowest point of units with third or<br>higher order streams, using Forest map.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| A12       | <u>Use restrictions</u> , recorded as the decile of a land unit<br>restricted to a given use. Thus 0 means the unit is not<br>restricted to that use, and a value of 10 means the use<br>is excluded from the unit. Only uses that are reasonably<br>controlled by legal access were included. Measurements<br>were made by transferring to working maps the relevant<br>information on EIS and Forest Service mine lease maps,<br>Forest Service firewood cutting and travel maps, BLM<br>surface and minerals ownership map, Forest Service<br>grazing allotments map, and Forest Service and EIS oil<br>and gas lease maps. Wildlife experts had designated a<br>mapped area as critical habitat for elk. The restric-<br>tions below follow general Forest Service policy even<br>though they may not be specifically followed in the<br>Blackfoot study area. |
|           | <ol> <li>Commercial logging - restricted on mine lease land<br/>with active mines, on campgrounds, and where roads are<br/>closed. Closed roads, outside of mine areas, are usually<br/>in area with erosion problems or critical habitat.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|           | <ol> <li>Firewood cutting - restricted on active mine lease<br/>areas, campgrounds, active timber sale areas, restricted<br/>travel areas, and private land.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|           | 3. Phosphate mining - restricted where no lease has been<br>approved. (Mining is not restricted on land with private-<br>ly owned mineral rights, regardless of existing leases.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|           | 4. Oil and gas exploration - restricted where no lease<br>has been approved. (No known restrictions in study area.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Indicator | Attribute, measurement method for indicator                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | 5. Cattle grazing - restricted from sheep allotments,<br>mining areas, campgrounds, critical habitat areas. (Does<br>not cover non-USFS land.)                                                                                                                                                                                                                                              |
|           | 6. Sheep grazing - restricted from cattle allotments,<br>mining areas, campgrounds, critical habitat areas.<br>(Does not cover non-USFS land.)                                                                                                                                                                                                                                              |
|           | 7. Hunting - restricted from active mine lease areas and private land.                                                                                                                                                                                                                                                                                                                      |
|           | 8. Hiking — restricted from active mine lease areas and private land.                                                                                                                                                                                                                                                                                                                       |
|           | 9. Roads - restricted from designated roadless or primitive areas. (None in study unit.)                                                                                                                                                                                                                                                                                                    |
|           | 10. Snowmobiling - restricted from active mine lease<br>areas, designated critical habitat areas, and private<br>land.                                                                                                                                                                                                                                                                      |
| •         | 11. Off road vehicles - restricted from active mine<br>lease areas, designated critical habitat or erosion<br>hazard areas (usually restrictions on leaving road<br>or trail with vehicle), and private land.                                                                                                                                                                               |
|           | 12. Buildings - restricted from roadless or primitive<br>areas and archeological resource areas.                                                                                                                                                                                                                                                                                            |
|           | 13. Fishing - restricted from active mine lease areas<br>and private land. (Technically, the water and streambed<br>are public property and use cannot be denied, but where<br>access to the stream bank is denied, fishing is restrict-<br>ed as a practical matter.)                                                                                                                      |
| A1 3      | Dead trees, interpreted from Forest Service color aerial<br>photos. Areas of apparent dead trees were recorded on<br>the working map and spot checked on the ground. The<br>photo identifications were accurate but not complete -<br>additional areas of dead trees were seen on the ground.<br>The data were recorded as a percent of the area with<br>significant numbers of dead trees. |
| A14       | Phosphorus outcrop, indicated as present (1) or not (0) in a unit as ascertained by using phosphate EIS map.                                                                                                                                                                                                                                                                                |
| A15       | Archeologic or historic site, determined from BLM unit<br>plan report (Lane's Grave and Lander's cutoff).                                                                                                                                                                                                                                                                                   |

Table 12. Continued.

| Indicator | Attribute, measurement method for indicator                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A16       | Minimum elevation, nearest 100 feet estimated for the<br>lowest spot in the land unit from contours on USGS<br>quadrangle maps.                                                                                |
| A17       | Maximum elevation, nearest 100 feet estimated for the highest spot in the land unit from contours on USGS quadrangle maps.                                                                                     |
| A18       | Maximum elevation of stream (for units with third or<br>higher order streams), lowest elevation of adjacent<br>upstream unit or elevation where two second order streams<br>join to form a third order stream. |

The attributes identified in Table 12 are either easily measured or readily obtainable from secondary sources. They include general land, vegetation, and ownership classification; road access descriptors; stream size and slope; the presence of legal restrictions to various uses; factors making an area suited or unsuited for a use; and elevation range and slope. None are costly to measure, and collectively they provide information that can go a long way toward predicting the suitability of a land unit for each of the uses.

The indicators from Table 13 originally proposed for use in reasonability index construction are outlined in Table 15. After collecting the data (Table 14), even this relatively simple outline proved more complex than could be supported with the limited information on use by land unit. The indicators actually used for assessing the reasonability of a given land unit for a given use are stated and combined into indices in Table 16. The resulting reasonability assessment (binary value of  $IR_{ui}$  in Equation 2) for each land use for each of the 343 land units are given in Table 17. Water uses were not covered because those occurring in the Upper Blackfoot Watershed are not explicit products of land use planning.

The 25 more difficult to quantify site attributes considered for employment in Equation 5 for estimating the intensity of a given use in a given unit are presented in Table 18. The measurements for the 343 units are recorded in Table 19. The attributes from Tables 13 and 18 originally proposed for estimating use intensities are shown in Table 20. Some uses cause impacts of significant public concern (Equation 6) and whose magnitude depends on other attributes of the land unit. Attributes suggested for consideration for this purpose are shown by use in Table 21, but this analysis was not taken further.

| Attribute | Number     | Mnemonic   | Units    | Data Item Definition                                              |
