#### THE RELIABILITY OF USU TELEMETRED

below each mountain top generator. Seeding during the 1967-68 winter will probably be from the Willard Mountain generator only, but additional seeding from one of the other generators later in the season is a possibility. The statistical design calls for point rather than line seeding, and for evaluation by comparison between the observed precipitation amounts in assumed target and control areas. The differences in storm precipitation characteristics between seeded and unseeded storms, for each of selected stations, will also be used as a basis for estimating the effectiveness of cloud seeding activities.

For the "target versus control" technique, the basic data will be the observed differences in the areaally averaged amounts of precipitation received at target and control stations. These areal averages will be calculated in the normal manner, separately for each storm, from actually measured precipitation amounts. However, there are several factors which contribute to each measured difference:

a. Natural differences. These may be either

(1) Topographic ( $\Delta P^t$ ), or

(2) Meteorological ( $\Delta P^m$ )

b. Instrumentation errors ( $\Delta P^I$ )

c. Exposure errors ( $\Delta P^E$ )

d. The precision factor, whether the results of manual or mechanical rounding ( $\Delta P^p$ )

and exposure effects ( $\Delta P_E$ ) are dependent upon wind speed. Change instrument errors ( $\Delta P_I$ ) may vary with temperature and wind conditions, amounts from storm to storm ( $\Delta P_m$ ), even with synoptic stratification, vary with flow patterns, and there is a natural variation in precipitation technique. However, the topographic effect ( $\Delta P_t$ ) at a station will be eliminated by applying the seeded versus unseeded storm At first glance it would seem that several of these contributors

$$-\Delta P_{co} - \Delta P_{os} - \Delta P_{AP}$$

$$\Delta P_s = \Delta P - \Delta P_t - \Delta P_m - \Delta P_I - \Delta P_E - \Delta P_{TC}$$

or

$$+ \Delta P_{os} + \Delta P_{AP} + \Delta P_s$$

$$\Delta P = \Delta P_t + \Delta P_m + \Delta P_I + \Delta P_E + \Delta P_p + \Delta P_{TC} + \Delta P_{co}$$

That is, if  $\Delta P$  is the calculated areal average difference, then

i. Possible seeding effects ( $\Delta P_s$ )

$$(\Delta P_{AP})$$

ii. Possible effects of inadvertent seeding by air pollution

and California ( $\Delta P_{os}$ )

iii. Possible effects from current seeding activities in Nevada e.g., Possible carry-over effects from previous seedings ( $\Delta P_{co}$ )

area ( $\Delta P_{TC}$ ).
