Introduction.

Rheumatoid arthritis is an exemplar long term condition, complicated by pain, disability, co-morbidities and long term medication use. It has significant effects on mobility, work performance, social role, sexual function and relationships. It is commonly associated with fatigue and mood disturbance as a result of complex interactions of physical (disease related) and psychosocial factors. ¹ NICE guidance recommends the availability of psychological support for these patients. ² We have implemented a psychology service for our patients with chronic rheumatological conditions. This study was set up to capture the value of this service.

Materials and methods.

Patients were assessed before and after psychology intervention using validated questionnaires; HAQ (disability), HADS (anxiety and depression), and a measure of patient self-efficacy. Structured interviews were used to analyse the value of the service to individual service users and analysed for themes. Finally Social Return on Investment (SROI) methodology was used to assess the monetary value of the service.³ SROI is a framework for measuring and accounting for the value created or destroyed by our activities – where the concept of value is much broader than that which can be captured by market prices. SROI seeks to reduce inequality and environmental degradation and improve wellbeing by taking account of this broader value.

Results.

Results demonstrate no change in HAQ scores, an improvement in HADS (anxiety and depression) and an improvement in self efficacy at the end of treatment.

Structured interviews identified the following themes; it gave patients permission to tell family and friends about the impact of the disease, it gave patients "tools" to aid management, it provided another perspective for exploring the disease, it enabled patients to be able to pull together all aspects of the disease. SROI demonstrated that the service was highly valued by the patients.

Conclusions.

Psychological support was very valuable to our patients with chronic rheumatological disease as demonstrated by SROI. It led to an improvement in anxiety and depression. Studies have demonstrated that higher levels of depression are associated with an increase in pain perception and disease activity assessments. ⁴ Psychology input did not lead to an improvement in disability but did lead to an improvement in patient self-efficacy which it is anticipated will lead to a decrease in health resource utilisation.⁵
