#### Abstract

Model transformations based on triple graph grammars (TGGs) have been applied in several practical case studies and they convince by their intuitive and descriptive way of specifying bidirectional model transformations. Moreover, fundamental properties have been extensively studied including syntactical correctness, completeness, termination and functional behaviour. But up to now, it is an open problem how domain specific properties that are valid for a source model can be preserved along model transformations such that the transformed properties are valid for the derived target model. In this paper, we analyse in the framework of TGGs how to propagate constraints from a source model to an integrated and target model such that, whenever the source model satisfies the source constraint also the integrated and target model satisfy the corresponding integrated and target constraint. In our main new results we show under which conditions this is possible. The case study shows how this result is successfully applied for the propagation of security constraints in enterprise modelling between business and IT models.

## 1 Introduction

Model integration and transformation between models as well as the compliance of such models with concrete security requirements have already been
studied in different application domains, especially in the context of enterprise modelling [2]. In detail, it was possible to present how triple graph grammars (TGGs) in the sense of Schürr [14] can be used to realize the integration and transformation of those models. In addition to that, graph constraints [4] were utilized to verify that business and IT models comply with given security requirements.

Figure 1: IT and business models with security requirements
However, it remained an open question how graph constraints valid for an IT model can be soundly propagated towards a corresponding business model. For example, the IT constraint on the left of Fig. 1 (public communication has to be encrypted) should be transformed into a corresponding business constraint (communication over public lines has to be filtered, right of Fig. 11). This problem was identified as an operational need in the decentralized organizational environment of Credit Suisse [2], where security requirements developed for IT models needed to be understood from the point of view of the corresponding business models in order to ensure that the different persons responsible for the business models, IT models and security requirements will be able to integrate, transform and verify these models successfully. While this paper presents the case study in concrete syntax the presented techniques are based on the underlying typed attributed abstract syntax graphs [4].

Furthermore, if an IT model satisfies the source constraint the corresponding business model should satisfy the target constraint. In general, given a requirement for a source model specified by a graph constraint we would like to construct a corresponding requirement for the corresponding target model with the following satisfaction property: Whenever a source model satisfies the given source graph constraint then the target model, de-
fined by the model transformation, satisfies the corresponding target graph constraint. In Fig. 1 the source model $G^{S}$ satisfies the source graph constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$, because for each match $p: P^{S} \rightarrow G^{S}$ (occurrence of the premise graph) there is morphism $q: C^{S} \rightarrow G^{S}$ (occurrence of the conclusion graph) with $q \circ a^{S}=p$.

In this paper we show under which conditions we are able to define a propagation from source graph to target graph constraints such that this satisfaction property is valid. First of all it makes sense to require strong functional behaviour of the model transformation, which implies that we have for each source model a unique target model. Moreover this allows for each source graph constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ with premise $P^{S}$, conclusion $C^{S}$ and embedding morphism $a^{S}$ to obtain a unique target graph constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$ by applying the model transformation to $P^{S}$ and $C^{S}$ leading to $P^{T}$ and $C^{T}$. For this construction we require that $P^{S}$ and $C^{S}$ are source models, i.e. $P^{S}, C^{S} \in V L_{S}$, where $V L_{S}$ is the source language of the model transformation $M T: V L_{S} \Rightarrow V L_{T}$. In this case the source graph constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ is called MT-consistent and leads to a MTconsistent target graph constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$. In Sec. 2 we review model transformation based on triple graph grammars [5, 14, 15] and prepare our case study based on a model transformation from business to IT-models.

Our first main result in Sec. 3 3 shows that the satisfaction property stated above for the propagation of security constraints is valid for $M T$-consistent source and target constraints. In Sec. 4 we discuss how to extend the theory to the case of partially MT-consistent constraints where premise or conclusion consist only of model fragments, s.t. model transformations are not directly applicable. Our constructions and results are illustrated by a case study of security constraints in enterprise modelling.Acknowledgement: This paper is a long version of our GT-VMT paper [6], and has been supported by the DFG-Project Behaviour GT.

## 2 Model Transformation between Business and IT Models

Triple graph grammars (TGGs) [14 are a well known approach for bidirectional model transformations and we apply TGGs to define the model transformation of our case study between business and IT models. For this purpose we review main constructions and results of model transformations based on triple graph grammars [15, [5] in this section.

Integrated models are defined as pairs of source and target graphs,
which are connected via a correspondence graph together with relating morphisms between these graphs. More precisely, a triple graph $G=\left(G^{S} \stackrel{s_{G}}{\leftrightarrows} G^{C} \xrightarrow{t_{G}} G^{T}\right)$ consists of three graphs $G^{S}, G^{C}$, and $G^{T}$, called source, correspondence, and target graphs, together with two graph morphisms $s_{G}: G^{C} \rightarrow G^{S}$ and $t_{G}: G^{C} \rightarrow G^{T}$.

A triple graph morphism $m: G \rightarrow H$ with $m=\left(m^{S}, m^{C}, m^{T}\right)$ consists of three graph morphisms $m^{S}: G^{S} \rightarrow H^{S}, m^{C}$ :
 $G^{C} \rightarrow H^{C}$ and $m^{T}: G^{T} \rightarrow H^{T}$ such that $m^{S} \circ s_{G}=s_{H} \circ m^{C}$ and $m^{T} \circ t_{G}=t_{H} \circ m^{C}$. A typed triple graph $G$ is typed over a triple graph $T G$ by a triple graph morphism type ${ }_{G}: G \rightarrow T G$ and a typed triple graph morphism $m:\left(G\right.$, type $\left._{G}\right) \rightarrow\left(H\right.$, type $\left._{H}\right)$ preserves the typing, i.e. type ${ }_{H} \circ m=$ type $_{G}$. Triple graphs may also contain attributed nodes and edges according to [5] and they form an $\mathcal{M}$-adhesive as well as weak adhesive HLR category for which several important formal results have been shown in (4].

Triple rules synchronously build up source and target graphs as well as their correspondence graphs, i.e. they are non-deleting. A triple rule $t r$ is an injective triple graph morphism $t r=$ $\left(t r^{S}, t r^{C}, t r^{T}\right): L \rightarrow R$ and w.l.o.g. we assume $t r$ to be an inclusion. Given an (almost) injective triple graph morphism $m: L \rightarrow G$, a triple graph transformation (TGT) step $G \stackrel{t r, m}{\longrightarrow} H$ from $G$ to a triple graph $H$ is given by a pushout of triple graphs with comatch $n: R \rightarrow H$ and transformation inclusion $t: G \hookrightarrow H$. Given a sequence of TGT-steps $G_{0} \xlongequal{t r_{1}, m_{1}} G_{1} \ldots \xlongequal{t r_{k}, m_{k}} G_{k}$ its trace is given by trace $=t_{k} \circ \ldots t_{2} \circ t_{1}$. A grammar $T G G=(T G, S, T R)$ consists of a triple type graph $T G$, a triple start graph $S$ and a set $T R$ of triple rules.

Example 1 (Triple Rules). The triple rules in Fig. 2 are part of the rules of the grammar TGG in [2]. They are presented in short notation, i.e. left and right hand sides of a rule are depicted in one triple graph. Elements, which are created by the rule, are labeled with green " ++ " and marked by green line colouring. The rule LANToDepartment creates LAN element in the IT model and a corresponding Department element in the Business model. The rule PublicToPublic generates public edges with gluing nodes in both domains simultaneously. The encryption/decryption nodes $(E / D)$ are created in front and at the end of a public Reo connector (depicted as black arrows) in the rule EDToFilter, where in the Business model a Filter is attached to the corresponding public Reo connector.

Figure 2: Some triple rules of the model transformation

The operational rules for model transformations based on TGGs are automatically derived from the set of triple rules $T R$ [5]. From each triple rule $t r$ we derive a forward rule $t r_{F}$ for forward transformation sequences and a source rule $t r_{S}$ for the construction resp. parsing of a model of the source language. By $T R_{S}$ and $T R_{F}$ we denote the sets of all source and forward rules derived from $T R$. The sets of backward rules $T R_{B}$ and target rules $T R_{T}$ are derived analogously as presented in [2].

## Example 2 (Forward Rule).

 The rule in Fig. 3 is the derived forward rule of the triple rule "EDToFilter" shown in Fig. ${ }^{2}$, No new elements are added in the source graph by this rule. The " $E / D$ " elements that are added by the triple rule have already to be present in a model

Forward Rule EDToFilter
Figure 3: A derived forward rule to make this rule applicable. Whereas the corresponding and target graphs and the morphisms remain the same as in the triple rule.

A set of triple rules $T R$ and the start graph $\varnothing$ typed over a triple graph $T G$ generate a visual language $V L$ of integrated models, i.e. models with elements in the source, target and correspondence component. The source language $V L_{S}$ and target language $V L_{T}$ are derived by projection to the
triple components, i.e. $V L_{S}=\operatorname{proj}_{S}(V L)$ and $V L_{T}=\operatorname{proj}_{T}(V L)$. For the $S$-component $T G^{S}$ and $T$-component $T G^{T}$ we denote by $V L\left(T G^{S}\right)$ and $V L\left(T G^{T}\right)$ the visual language of all source and target models typed over $T G^{S}$ and $T G^{T}$ respectively. This means we have $V L_{S} \subseteq V L\left(T G^{S}\right)$ and $V L_{T} \subseteq V L\left(T G^{T}\right)$.

As presented in [5] the derived operational rules provide the basis to define model transformations based on source consistent forward transformations $G_{0} \Rightarrow^{*} G_{n}$ via $\left(t r_{1, F}, \ldots, t r_{n, F}\right)$, short $G_{0} \xlongequal{t r_{F}^{*}} G_{n}$. A forward sequence $G_{0} \xrightarrow{t r_{F}^{*}} G_{n}$ is source consistent, if there is a source sequence $\varnothing \xrightarrow{t r_{S}^{*}} G_{0}$ such that the sequence $\varnothing \xrightarrow{t r_{S}^{*}} G_{0} \xlongequal{t r_{F}^{*}} G_{n}$ is match consistent, i.e. the $S$-component of each match $m_{i, F}$ of $\operatorname{tr}_{i, F}(i=1 \ldots n)$ is uniquely determined by the comatch $n_{i, S}$ of $t r_{i, S}$, where $t r_{i, S}$ and $t r_{i, F}$ are source and forward rules of the same triple rules $t r_{i}$. Thus, source consistency is a control condition for the construction of the forward sequence.

Definition 1 (Model Transformation Based on Forward Rules). A model transformation sequence is given by a tuple $\left(G_{S}, G_{0} \xlongequal{t r_{F}^{*}} G_{n}, G_{T}\right)$ consisting of a source graph $G_{S}$, an integrated graph $G=G_{n}$, and a target graph $G_{T}$, and a source consistent forward sequence $G_{0} \xlongequal{\operatorname{tr}_{F}^{*}} G_{n}$ with $G_{S}=$ $G_{0}^{S}$ and $G_{T}=G_{n}^{T}$. A model transformation $M T: V L\left(T G^{S}\right) \Rightarrow V L\left(T G^{T}\right)$ based on forward rules is given by a set of model transformation sequences $\left(G_{S}, G_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} G_{n}, G_{T}\right)$ with $G_{S} \in V L\left(T G^{S}\right)$ and $G_{T} \in V L\left(T G^{T}\right)$.

Model transformations based on forward rules using the control condition "source consistency" are syntactically correct and complete as shown in [5, 11]. Correctness means that for each source model $G^{S}$ that is transformed into a target model $G^{T}$ there is an integrated model $G=\left(G^{S} \leftarrow G^{C} \rightarrow G^{T}\right)$ in the language of integrated models $V L$ generated by the TGG. Completeness ensures that for each valid source model there is always a forward transformation sequence that transforms it into a valid target model, and if the source model is not in $V L_{S}$ then there is no source consistent forward transformation sequence. Therefore, we can apply the on-the-fly construction presented in 5 to any given source model and ensure that we derive a correct corresponding target model and if all source rules are creating then we can always ensure termination.

Example 3 (Model Transformation). The model transformation from IT to business models via the forward rules of the triple rules in Ex. 11 transforms the source model $G^{S}$ in Fig. 1 into the target model $G^{T}$ in Fig. 1 as presented in [2]. Using backward and target rules we obtain a model transformation from business to IT models and all together we obtain a bidirectional model
transformation, where both directions are useful in different phases of enterprise modelling. Especially a propagation of constraints from IT to business models will be considered in Sec. 3.

## 3 Propagation of MT-consistent Constraints

The propagation of constraints along a given model transformation aims at translating requirements from the source domain to the corresponding target domain in order to verify them at corresponding target models. In this section we present a constructive approach for the propagation of constraints based on a given model transformation and we show by Thm. 1 how each source constraint can be propagated to an integrated and a target constraint for the languages of integrated and target models, respectively. In our main result Thm. 2 we show that under suitable conditions the propagation preserves the validity of constraints. An (atomic) constraint $P C(a: P \rightarrow C)$ for a triple graph is given by a premise $P$ and a conclusion $C$ connected by a morphism $a: P \rightarrow C$. A graph $G$ satisfies $P C(a: P \rightarrow C)$, if for each injective $p: P \rightarrow G$ there is an injective $q: C \rightarrow G$ with $q \circ a=p$. Atomic constraints can be combined to general constraints as usual by boolean operators.

The first important property for ensuring the creation of propagated constraints for a given source constraint is $M T$-consistency meaning that the constraint has to be compatible with the model transformation $M T$. We take into account a domain specific source language $\mathcal{L}_{S}$ which should be a sublanguage of $V L_{S}$, i.e. $\mathcal{L}_{S} \subseteq V L_{S}$, usually restricted by additional constraints.

Definition 2 ( $M T$-consistent Constraints). Given a model transformation $M T: V L_{S} \Rightarrow V L_{T}$, then a constraint is $M T$-consistent, if the corresponding condition below is satisfied.

| constraint kind |  | typed over | condition |
| ---: | :--- | :--- | :--- |
| source constraint | $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ | $T G^{S}$ | $P^{S}, C^{S} \in \mathcal{L}_{S} \subseteq V L_{S}$ |
| integrated constraint | $P C(a: P \rightarrow C)$ | $T G$ | $P, C \in V L$ |
| target constraint | $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$ | $T G^{T}$ | $P^{T}, C^{T} \in V L_{T}$ |

Moreover, the sound propagation of constraints is based on the notion of propagation consistency, which requires strong functional behaviour of the model transformation and one further technical condition.

Definition 3 (Propagation Consistency and Strong Functional Behaviour of Model Transformations). A model transformation $M T$ is propagation consistent, if:

- The model transformation $M T$ has strong functional behaviour with respect to $\mathcal{L}_{S}$. This means that matches are injective and for each source graph $G_{S} \in \mathcal{L}_{S} \subseteq V L_{S}$ the execution of $M T$ terminates resulting in a model transformation sequence $\left(G_{S}, G_{0} \xlongequal{t r_{F}^{*}} G_{n}, G_{T}\right)$, and moreover, any two source consistent forward sequences $G_{0} \stackrel{t r_{r}^{*}}{\Longrightarrow} G_{n}$ and $G_{0} \xlongequal{\overline{t r}_{F}^{*}} \bar{G}_{m}$ constructed via $M T$ that cannot be extended by any further step via $M T$ are switch-equivalent up to isomorphism, i.e. the rules of $t r_{F}^{*}$ are a permutation of those in $\overline{t r}_{F}^{*}, n=m$ and $G_{n} \cong G_{m}$.
- Furthermore, each triple graph $G=\left(G^{S} \stackrel{s_{G}}{\leftarrow} G^{C} \xrightarrow{t_{G}} G^{T}\right) \in V L$ has to be left-linear, i.e. we have that $s_{G}$ is injective.

Remark 1 (Checking Propagation Consistency). Concerning the first condition (strong functional behaviour), we have presented in [11 how model transformations based on forward rules are checked for strong functional behaviour using the tool AGG for critical pair analysis. For the second condition (left linearity) it suffices to show that no rule is capable to transform a triple graph $G=\left(G^{S} \stackrel{s_{G}}{\leftrightarrows} G^{C} \xrightarrow{t_{G}} G^{T}\right)$ into a triple graph $H=\left(H^{S} \stackrel{s_{H}}{\leftrightarrows}\right.$ $H^{C} \xrightarrow{t_{H}} H^{T}$ ) with non-injective $s_{H}$. This condition is ensured if there is no triple rule which simultaneously creates a correspondence element $c$ and relates it to an existing source element $s \in L^{S}$, i.e. we require for all rules that $\left[c \in R^{C} \backslash L^{C} \wedge s_{R}(c)=s\right] \Rightarrow\left[s \notin L^{S}\right]$. Both conditions have been verified for our case study.

In our first main result we show how each source constraint can be propagated into an integrated and a target constraint as shown by the example in Fig 4 which happens to be exactly the rule EDToFilter. Note that in general those graphs are not necessarily the same. Intuitively, the transformation steps of the premise graph $P$, which is contained in the conclusion graph $C$, are transferred to the transformation steps for $C$ and the transformation of $C$ is completed for the remaining parts in $C$.

Theorem 1 (Propagation and Restriction of Constraints). Given a TGG model transformation MT with strong functional behaviour, then

1. an MT-consistent source constraint $P C\left(a^{S}\right)$ generates an $M T$-consistent integrated constraint $P C(a)$, called propagated integrated constraint, where $a^{S}$ is the source component of $a$ and diagrams (1) and (2) below

Target constraint publiclsFiltered for business models
and

Figure 4: Source constraint as well as propagated integrated and target constraints
commute using the trace morphisms of the transformation sequences.
2. an MT-consistent integrated constraint $P C(a)$ can be restricted to and an MT-consistent target constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$.

Proof. 1. Given $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ with $P^{S}, C^{S} \in \mathcal{L}_{S} \subseteq V L_{S}$, then the completeness result implies $P_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} P_{l}=P$ with $P \in V L$. Moreover this MT-sequence can be extended along $\left(a^{S}, \emptyset, \emptyset\right): P_{0} \rightarrow C_{0}$ with induced forward consistent matches leading to (1). This extension property based on forward consistent matches can be deduced directly by the equivalence of transformation steps via the on-the-fly construction and transformation steps via the corresponding forward translation rules in 11 and the fact that the gluing condition is always satisfied for forward translation steps shown in [11]. Since $M T$ is propagation consistent, we have by condition 1 of Def. 3 (strong functional behaviour) that any two transformation sequences starting at $C_{0}$ that cannot be
extended any further are switch equivalent up to isomorphism. Hence, $C_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} C_{l}$ can be extended to $C_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} C_{l} \xrightarrow{\operatorname{tr}^{\prime \prime}}{ }_{P} C_{n}$ with $C_{n} \in V L$.
Now we define $a:=\operatorname{trace}_{C 2} \circ a_{l}: P \rightarrow C$ s.t. (2) commutes. The integrated constraint $P C(a: P \rightarrow C)$ is MT-consistent because $P, C \in$ $V L$.
2. Given an integrated constraint $P C(a: P \rightarrow C)$ with $P, C \in V L$, then $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$ has $P^{T}, C^{T} \in V L_{T}$ by definition of $V L_{T}=\operatorname{proj}_{T}(V L)$. Hence we have the required MT-consistency of the target constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$.

Figure 5: Propagated Integrated Constraint
Example 4 (Propagation). According to Rem. 1 the model transformation of our case study is propagation consistent. Furthermore, the source constraint is MT-consistent, such that we can apply Thm. 1 and derive the propagated integrated and target constraints in Fig. 5. For better visibility we take a subgraph $G^{\prime} \subseteq G$ of the integrated model $G$ in Ex. 3, such that the source model $G^{\prime S}$ is similarly transformed into the target model $G^{\prime T}$. Now, the integrated model $G^{\prime}$ satisfies the propagated integrated constraint, i.e. for any injective occurrence $p: P \rightarrow G^{\prime}$ of the integrated premise $P$ in $G^{\prime}$ there is an injective occurrence $q: C \rightarrow G^{\prime}$ compatible with the constraint morphism $a$, i.e. $p=q \circ a$.

In order to generally ensure the validity of propagated constraints we provide a suitable static condition on constraints by Def. 4 below that can be checked automatically (see Remark 22). Essentially, the condition requires that whenever the premise graph $P$ of a constraint is found in an integrated model, then its occurrence is already fully determined by the source and correspondence component. This condition is not very restrictive, because it must only hold for premise graphs of constraints and not for all integrated graphs in $V L$.

Definition 4 (Admissable Premise). Given a TGG with triple language $V L$. The premise $P$ of an integrated constraint $P C(a: P \rightarrow C)$ is called admissable, if for any injective morphisms $p, p^{\prime}: P \rightarrow G$ with $G \in V L$ we have $p^{S}=p^{\prime S}$ and $p^{C}=p^{\prime C}$ implies $p^{T}=p^{\prime T}$.

Remark 2 (Checking Admissability). It suffices to show that the internal morphism $t_{P}: P^{C} \rightarrow P^{T}$ of the premise graph $P$ is surjective on nodes, and furthermore, for each edge type occurring in the target component $P^{T}$ of $P$ we have that there are no parallel edges in any triple graph $G \in V L$ of this type. The latter can be verified - especially in our case study - by checking that the triple rules do not create edges of those types separately, but always together with an adjacent node.

The premise graph of a propagated target constraint may occur with a target model at places that do not correspond to occurrences of the premise graph of the source constraint in the source model, because differently typed source elements may be transformed into target elements of the same type. From the application point of view, it is clear that the preservation of properties of the source model can be ensured only at corresponding occurrences in the target model. Theorem 2 below shows that the validity of source constraints is preserved at those places using the notion of weak satisfaction. More precisely, given an integrated constraint $P C(a: P \rightarrow C)$, then a target model $G^{T}$ weakly satisfies a target constraint - written $\left(G^{T} \models^{w} P C\left(a^{T}\right)\right)$ - if for all injective $p^{T}: P^{T} \rightarrow G^{T}$ which can be extended to an injective integrated morphism $p: P \rightarrow G$ there exists an injective $q^{T}: C^{T} \rightarrow G^{T}$ with $q^{T} \circ a^{T}=p^{T}$. Furthermore, the theorem shows that the validity is completely preserved for the propagated integrated constraint. It is formulated for (atomic) constraints $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ but can be extended to general constraints. For the proof of Thm. 2 we will first introduce the following lemma.

Lemma 1 (Source Uniqueness). Given a left linear triple graph $G \in V L$ and an admissible premise $P$ of a triple graph constraint $P C(a)$. Then, $\forall$ injective $p, p^{\prime}: P \mapsto G:\left(p^{S}=p^{\prime S}\right) \Rightarrow\left(p=p^{\prime}\right)$.

Proof. Given injective triple graph morphisms $p, p^{\prime}: P \rightharpoondown G$, with $p^{\prime S}=p^{S}$ (precondition ( $P 1$ ) of Lem, 11). Since $p$ and $p^{\prime}$ are triple graph morphisms, we have that $(7 S)$ and $(7 T)$ below commute.

Thus, we have that $s_{G} \circ p^{\prime C}=p^{\prime S} \circ s_{P}=p^{S} \circ s_{P}=s_{G} \circ p^{C}$ using precondition $(P 1): \quad p^{\prime S}=p^{S}$. Therefore, we have conclusion $1(C 1): \quad s_{G} \circ p^{\prime C}=s_{G} \circ p^{C}$. Furthermore, we have that $M T$ is propagation consistent, thus we have by condition 2 of Def. 3 that $s_{G}$ is injective and therefore a monomorphism. This implies conclusion $2(C 2): \quad p^{\prime C}=p^{C}$.

Accordingly, we have that $t_{G} \circ p^{C}=p^{T} \circ t_{P} \wedge t_{G} \circ p^{\prime C} \stackrel{(C 1)}{=} t_{G} \circ p^{C}=p^{\prime T} \circ t_{P}$. Thus, we have conclusion $3(C 3): p^{T} \circ t_{P}=p^{\prime T} \circ t_{P}$. The precondition that $P$ is admissible (Def. 4) implies conclusion $4(C 4): p^{T}=p^{\prime T}$. Thus, we can combine $(P 1),(C 2)$ and ( $C 4$ ) leading to $p=p^{\prime}$.

Theorem 2 (Validity of Propagation for MT-Consistent Constraints). Given a propagation consistent model transformation MT acc. to Def. 3, and given an MT-consistent source graph constraint $P C\left(a^{S}: P^{S} \rightarrow\right.$ $\left.C^{S}\right)$ with an MT-consistent propagated integrated constraint $P C(a: P \rightarrow C)$ and a propagated target constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$ according to Thm. 1, such that $P$ is admissable, then we have for all $G^{S} \in \mathcal{L}_{S}$ with model transformation sequence $\left(G^{S}, G_{0} \xlongequal{t r_{P}^{*}} G, G^{T}\right)$ :

$$
\left(G^{S} \models P C\left(a^{S}\right)\right) \Rightarrow\left(G \models P C(a) \wedge G^{T} \models^{w} P C\left(a^{T}\right)\right) .
$$

This means that given the source graph satisfies the source constraint, then the integrated graph satisfies the propagated integrated constraint and the target graph weakly satisfies the propagated target constraint.

Proof. First we show $G^{S} \models P C\left(a^{S}\right)$ implies $G \models P C(a)$. Given injective $p: P \rightarrow G$ we have to find an injective morpism $q: C \rightarrow G$ with $q \circ a=p$. By assumption there is an injective morphism $q^{S}: C^{S} \rightarrow G^{S}$ with $q^{S} \circ a^{S}=p^{S}$. $M T$-consistency of $P C\left(a^{S}\right)$ implies that $P C(a)$ is $M T$-consistent and (1) as well as (2) commute by Thm. 1.

Moreover, $q^{S} \circ a^{S}=p^{S}$ implies commutativity of (3). Now, $C_{0} \xlongequal{\text { tr** }}$ $C_{l} \xrightarrow{\operatorname{tr}^{\prime *}{ }_{F}} C_{n}=C$ and $\left(q^{S}, \emptyset, \emptyset\right): C_{0} \rightarrow G_{0}$ leads step by step to $G_{0} \xlongequal{t r_{F}^{*}} G_{l} \xlongequal{t r_{F}^{\prime *}} G_{n}$ with commutative (4), (5). Since $M T$ is propagation consistent we have by condition 1 of Def. 3 that all transformation sequences starting at $G_{0}$ that cannot be extended any further are switch equivalent up to isomorphism. Hence, $G_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} G_{l} \xrightarrow{\operatorname{trr}_{F}^{*}} G_{n}$ can be extended to source consistent $G_{0} \xlongequal{t r_{F}^{*}} G_{l} \xlongequal{t r^{\prime}{ }_{F}^{*}} G_{n} \xlongequal{t r^{\prime \prime *}}{ }_{F} G_{m}$ with $G_{m} \in V L$. Now $G \in V L$ implies a source consistent transformation sequence $s 1=\left(G_{0} \xrightarrow{t^{\prime \prime \prime \prime *}} \underset{F}{P} G\right)$ which by strong functional behaviour can be switched to $s 2=G_{0} \xrightarrow{\operatorname{tr}_{F}^{*}} G_{l} \xrightarrow{\operatorname{tr}^{\prime *}{ }_{F}} G_{n} \xlongequal{\operatorname{tr}^{\prime \prime *} *} G$ and we derive $G_{m} \cong G$ and w.l.o.g. $G_{m}=G$. We define $q=$ trace $_{G_{3}} \circ q_{n}$. Note that $q$ is injective, because $\left(q^{S}, \emptyset, \emptyset\right)$ is injective and (4) + (5) preserve injectivity using the fact that pushouts of triple graph morphisms preserve injectivity. Note that commutativity of (1) and (2) implies that $a^{S}$ is the source component of $a$ and commutativity of (4) and (5) implies that $q^{S}$ is the source component of $q$. By (3) we have $q^{S} \circ a^{S}=p^{S}$. By Lem. 1 (Source Uniqueness) we can deduce that $q \circ a=p$ as required (7). Finally, to show $G^{T} \models^{w} P C\left(a^{T}\right)$ we assume that there is an injective $p^{T}: P^{T} \rightarrow G^{T}$ which can be extended to $p: P \rightarrow G$. By $G \models P C(a)$ we have that there is an injective morphism $q: C \rightarrow G$ with $q \circ a=p$. Thus we have an injective morphism $q^{T}: C^{T} \rightarrow G^{T}$ with $q^{T} \circ a^{T}=p^{T}$.

Example 5 (Validity of Propagated Constraints). The premise graph of the integrated constraint in Fig. 5 is admissable, which we verified via Remark 2. According to Ex. 4 the model transformation is propagation consistent and the source as well as the propagated constraints are MT-consistent. Therefore, we can apply Thm. 园 for showing that the integrated model $G^{\prime}$
satisfies the propagated integrated constraint and the target model ${G^{\prime}}^{T}$ weakly satisfies the propagated target constraint $P C\left(a^{T}: P^{T} \rightarrow C^{T}\right)$ in Fig. 4, i.e. the constraint holds at all structures that correspond to occurrences of the source constraint in the source model.

## 4 Propagation of Partially MT-consistent Constraints

In this section we discuss how to generalize constructions and results of Sec. 3 to the case of partially MT-consistent constraints, i.e. for the source constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ we may have $P^{S} \notin \mathcal{L}_{S} \subseteq V L_{S}$ or $C^{S} \notin \mathcal{L}_{S}$ as shown in Fig. 6a. Note that in Fig. 6a black bullets are missing s.t. $P^{S}$ is a model fragment in contrast to $P^{S}$ in Fig. 4. Moreover, $P^{S}$ in concrete syntax in Fig. 6a corresponds to a single node in abstract syntax in Fig. 6b. If $P^{S} \notin \mathcal{L}_{S}$ or $C^{S} \notin \mathcal{L}_{S}$ they can be considered as model fragments and we show now how to handle this important more general case. The main idea is to use an extended model transformation approach for model fragments introduced in [13] based on the general framework of graph transformation with borrowed context (BC) [8]. Intuitively, BC-transformations allow for partial matching of the forward rules in the S -component. The missing context that is required by the left hand side $L_{F}$ of the forward rule is borrowed and the instance graph is extended by this context. More precisely each BC-forward transformation step consists of two POs (1) and (2), where in PO (1) the partial match is completed and in PO (2) we have a forward transformation step with total match.
(a)

(b)

Figure 6: Partially MT-consistent source constraint (a) and abstract syntax of $P^{S}$ (b)
Definition 5 (BC-Forward and BC-Model Transformation). Given triple rules $T R$ with corresponding forward rules $T R_{F}$ then

1. A $B C$-forward transformation $\widehat{G}_{0} \stackrel{t r}{*}_{\Longrightarrow}^{P C} \widehat{G}_{n}$ via $T R_{F}$ is given by BC-forward transformation steps $\widehat{G}_{i-1} \xlongequal{\operatorname{tr}_{i, F}, \widehat{m}_{i, F}, d_{i}} \widehat{G}_{i}$ for $i=1, \ldots, n$ consisting of POs (1) and (2) where in PO (1) the partial match $m^{\prime}: L_{i, F} \rightharpoonup \widehat{G}_{i-1}-$ given by injective morphisms $\widehat{m}_{i, F}$ and $d_{i}-$ is extended to a total injective match $m_{i, F}^{+}: L_{i, F} \rightarrow \widehat{G}_{i-1}^{+}$and in $\mathrm{PO}(2)$
we have a forward transformation step with total injective match as in Sec. 2. Moreover we require that the $C$ - and $T$-components $d_{i}^{C}$ and $d_{i}^{T}$ of $d_{i}$ are identities. Note that the $S$-component $t r_{i, F}^{S}$ is the identity of $R_{i}^{S}$ by construction of $T R_{F}$, i.e. $\operatorname{tr}_{i, F}^{S}=i d_{R_{i}^{S}}$.

2. A BC-model transformation sequence $\left(G_{S}, \widehat{G}_{0}{ }^{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{G}_{n}, G_{T}\right)$ consists of a source consistent BC-forward transformation $\widehat{G}_{0} \stackrel{\text { tr }_{F}^{*}}{\Longrightarrow}{ }_{B C} \widehat{G}_{n}$ via $T R_{F}$ with source model $G_{S}=\widehat{G}_{n}^{S}$ and target model $G_{T}=\widehat{G}_{n}^{T}$. A $B C$-model transformation $M T_{B C}: V L\left(T G^{S}\right) \nRightarrow_{B C} V L\left(T G^{T}\right)$ consists of BC-model transformation sequences $\left(G_{S}, \widehat{G}_{0}{ }^{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{G}_{n}, G_{T}\right)$ with $G_{S} \in V L\left(T G^{S}\right)$ and $G_{T} \in V L\left(T G^{T}\right)$.

Remark 3 (Source Consistency). Source consistency of BC-forward transformations is based on partial BC-match consistency [13], where both notions are defined in analogy to source and match consistency in the standard case without BC [5].

BC-forward and BC-model transformations can be extended by Fact 1 to forward and model transformations in the sense of Sec. 2.

Fact 1 (Extension of BC-Forward and BC-Model Transformations).

1. Given a $B C$-forward transformation sequence $\widehat{G}_{0}{ }^{t t_{F}^{*}}{ }_{B C} \widehat{G}_{n}$ with $\widehat{G}_{0}=\left(\widehat{G}_{0}^{S} \leftarrow \emptyset \rightarrow \emptyset\right)$ there is an extension to a forward transformation sequence $G_{0} \xlongequal{\text { tr }}{ }_{F}^{*} G_{n}$ with $G_{0}=\left(\widehat{G}_{n}^{S} \leftarrow \emptyset \rightarrow \emptyset\right)$ and $G_{n}=\widehat{G}_{n}$.
2. Moreover, each $B C$-model transformation sequence $\left(G_{S}, \widehat{G}_{0} \xlongequal{\operatorname{tr}_{F}^{*}}{ }_{B C}\right.$ $\left.\widehat{G}_{n}, G_{T}\right)$ with $G_{S}=\widehat{G}_{n}^{S}, G_{T}=\widehat{G}_{n}^{T}$ can be extended to a model transformation sequence $\left(G_{S}, G_{0} \xlongequal{\text { tr }_{F}^{*}} G_{n}, G_{T}\right)$ with the same $G_{S}, G_{T}$ satisfying $G_{S}=G_{0}^{S}, G_{T}=G_{n}^{T}$ and $G_{n}=\widehat{G}_{n}$.

Construction. Given the BC-forward transformation $\widehat{G}_{0} \stackrel{t r_{F}^{*}}{\longrightarrow} \widehat{G}_{n}$ with $\widehat{G}_{0}^{C}=\widehat{G}_{0}^{T}=\emptyset$ by POs (1)-(6) and $G_{0}=\left(\widehat{G}_{n, S} \leftarrow \emptyset \rightarrow \emptyset\right)$ we construct diagrams (7)-(12) in the S-, C-, and T-component as follows, where all morphisms are injective:

Figure 7: Extension of a BC-forward Transformation Sequence

S-Component The S-components $g_{0, S}^{+}, g_{1, S}^{+}, \ldots, g_{n-1, S}^{+}$are identical because of POs (2)-(6) and identical $t r_{F, S}^{1}, t r_{F, S}^{2}, \ldots, t r_{F, S}^{n}$. Then $h_{0, S}, h_{1, S}, \ldots, h_{n, S}$ are constructed as identities in view of POs (8), (10) and (12):

$$
\begin{aligned}
f_{1, S} & =g_{n-1, S} \circ \ldots \circ g_{1, S}: \widehat{G}_{1, S} \rightarrow \widehat{G}_{n, S}=G_{0, S}=G_{1, S} \\
\vdots & \\
f_{n, S} & =i d: \widehat{G}_{n, S} \rightarrow \widehat{G}_{n, S}=G_{0, S}=G_{1, S} \\
f_{0, S}^{+} & =f_{1, S}: \widehat{G}_{0, S}^{+}=\widehat{G}_{1, S} \rightarrow G_{1, S}=G_{0, S} \\
f_{1, S}^{+} & =f_{2, S}: \widehat{G}_{1, S}^{+}=\widehat{G}_{2, S} \rightarrow G_{2, S}=G_{1, S} \\
\vdots & \\
f_{n-1, S}^{+} & =f_{n, S}: \widehat{G}_{n-1, S}^{+}=\widehat{G}_{n, S} \rightarrow G_{n, S}=G_{n-1, S}
\end{aligned}
$$

C-Component The C-components $g_{0, C}, g_{1, C}, \ldots, g_{n-1, C}$ are identical because of POs (1), (3), (5) and identical $d_{1, C}, d_{2, C}, \ldots, d_{n, C}$. Then

$$
\begin{aligned}
f_{0, C}^{+}=f_{0, C}=\emptyset & \text { with } \widehat{G}_{0, C}=\widehat{G}_{0, C}^{+}=G_{0, C}=\emptyset \\
f_{1, C}, h_{0, C} & \text { by PO (8) and } f_{1, C}^{+}=f_{1, C} \text { using } g_{1, C}=i d \\
f_{2, C}, h_{1, C} & \text { by PO (10) and } f_{1, C}^{+}=f_{1, C} \text { using } g_{2, C}=i d \\
\vdots & \\
f_{n, C}, h_{n-1, C} & \text { by PO (12) }
\end{aligned}
$$

T-Component Replace C by T in $C$-Component.

Proof of Fact 1, Part 1. First we show that diagrams (7)-(12) commute componentwise and (8), (10) and (12) are POs componentwise.

## S-Component

$$
\begin{align*}
& f_{0, S}^{+} \circ g_{0, S}=f_{1, S} \circ g_{0, S}=f_{0, S}  \tag{7}\\
& f_{1, S}^{+} \circ g_{1, S}=f_{2, S} \circ g_{1, S}=f_{1, S} \\
& f_{n-1, S}^{+} \circ g_{n-1, S}=f_{n, S} \circ g_{n-1, S}=i d \circ g_{n-1, S}=f_{n-1, S}
\end{align*}
$$

(8), (10), and (12) are POs in the S-component because the horizontal morphisms are identities.

C-Component (7), (9), and (11) commute by construction, e.g. $f_{0, C}^{+} \circ g_{0, C}=$ $f_{0, C}^{+} \circ i d=f_{0, C}$.
(8), (10), and (12) are POs in the C-component by construction.

T-Component Similar to C-component.
Assume now that all new morphisms in (7)-(12) are TGG-morphisms such that (8), (10), and (12) become TGG-POs. In this case the forward transformation $G_{0} \xlongequal{t r_{F}^{*}} G_{n}$ is given by POs (2) + (8), (4) + (10), and (6) $+(12)$ with $G_{0}=\left(\widehat{G}_{n, S} \leftarrow \emptyset \rightarrow \emptyset\right)$ and $G_{n}=\widehat{G}_{n}$, because we have $f_{n}=i d$, with $f_{n, S}=i d$ by construction and $f_{0, C}^{+}=i d$ implies by POs (8), (10), and (12) also $f_{n, C}=i d$ and similar $f_{n, T}=i d$.

It remains to show step by step that all morphisms in (7) - (12) are TGG-morphisms and $G_{1}, \ldots, G_{n}$ are well-defined such that (8), (10), and (12) become TGG-POs.

First of all $G_{0}=\left(\widehat{G}_{n, S} \leftarrow \emptyset \rightarrow \emptyset\right)$ and $f_{0}=\left(f_{0, S}, \emptyset, \emptyset\right), f_{0}^{+}=\left(f_{0, S}^{+}, \emptyset, \emptyset\right)$ are well-defined TGG-morphisms. Since (8) is already PO in each component there are unique graph morphisms $G_{i, C} \rightarrow G_{i, S}$ and $G_{i, C} \rightarrow G_{i, T}$ s.t. $G_{1}=$ $\left(G_{1, S} \leftarrow G_{1, C} \rightarrow G_{1, T}\right)$ is a TGG-graph, $f_{1}$ and $h_{0}$ are TGG-morphisms, and (8) is a TGG-PO.

In order to show that $f_{1}^{+}$is TGG-morphism we have to show that (15), (16) commute, while (13), (14) and the composite diagrams commute because $g_{1}$ and $f_{1}$ are TGG-morphisms respectively.

Since $\widehat{G}_{1, C}^{+}$is PO in the C-component of (3) we have that $g_{1, C}$ and $\widehat{m}_{2, F, C}^{+}$ are jointly epi and it is sufficient to show that (15) and (16) commute if they are composed with these both morphisms. Concerning composition with $g_{1, C}$ this follows from commutativity of (13), (14), the vertical composed diagrams and the triangles in each component.

For the composition of (15) and (16) with $\widehat{m}_{2, F, C}^{+}=\widehat{m}_{2, F, C}^{+} \circ i d_{C}$ we consider the following diagrams corresponding to diagram (3) and (9) in the construction, where $i d_{C}$ and $i d_{T}$ are identities by definition of BC-forward transformations.

We know by construction that all subdiagrams except for (15) and (16) commute. This implies that (15) and (16) composed with $\widehat{m}_{2, F, C}^{+}$commute and hence also (15) and (16) commute using ( $g_{1, C}, \widehat{m}_{2, F, C}^{+}$) are jointly epi. This implies that $f_{1}^{+}$is TGG morphism.

Similar to $f_{1}$ and $h_{0}$ above using TGG-morphism $f_{0}^{+}$we can conclude now a unique TGG-graph $G_{2}$ s.t. (10) becomes TGG-PO with TGG-morphisms $f_{2}$ and $h_{1}$. Similar to $f_{1}^{+}$also $f_{2}^{+}$is TGG-morphism. This can be iterated for all $i=0, \ldots, n$ s.t. the diagrams (7)-(12) are TGG-diagrams with TGG-POs (8), (10), and (12).

Proof of Fact 1, Part 2. By definition of the BC-model transformation sequence in Thm. 4 in [13] we have for the BC-model transformation sequence given in our theorem a partial BC-match consistent pair ( $G_{00} \xrightarrow{t r_{s}^{*}}$ $G_{n 0}, \widehat{G_{0}}{\stackrel{t r_{F}^{*}}{\Longrightarrow}}_{B C} \widehat{G}_{n}$ ) with inclusion $G_{n, 0} \hookrightarrow \widehat{G}_{n}, G_{S}=\widehat{G}_{n}^{S}, G_{T}=\widehat{G}_{n}^{T}$ and $\widehat{G_{n}^{S}}=G_{n, 0}$. By Thm. 6 in [13] we have a partially match consistent sequence $G_{00} \xrightarrow{t r_{s}^{*}} G_{n 0} \hookrightarrow G_{0} \xrightarrow{t r_{F}^{*}} G_{n}$. By the first part of Fact 1 we have $G_{n}=\widehat{G}_{n}$ and $G_{0}^{S}=\widehat{G}_{n}^{S}$. Hence we have $G_{n 0}=\widehat{G}_{n}^{S}=G_{0}^{S}$, which means that according to Thm. 1 in [5 a model transformation sequence $\left(G_{S}^{\prime}, G_{0} \xlongequal{\operatorname{tr}_{F}^{*}} G_{n}, G_{T}^{\prime}\right)$
with $G_{S}^{\prime}=G_{0}^{S}$ and $G_{T}^{\prime}=G_{n}^{T}$. Finally we have $G_{S}^{\prime}=G_{0}^{S}=\widehat{G}_{n}^{S}=G_{S}$ and $G_{T}^{\prime}=G_{n}^{T}=\widehat{G}_{n}^{T}=G_{T}$ by Thm. 4 in [13]. Hence we have model transformation $\left(G_{S}, G_{0} \xrightarrow{t r_{F}^{*}} G_{n}, G_{T}\right)$ with $G_{S}=G_{0}^{S}$ and $G_{T}=G_{n}^{T}$.

Now correctness of model transformation shown in [5, 11] can be extended by Fact 2 to BC-model transformation.

Fact 2 (Correctness of BC-Model Transformations). Each BC-model transformation is correct, i.e. for all $B C$-model transformation sequences $\left(G_{S}, \widehat{G}_{0} \xrightarrow{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{G}_{n}, G_{T}\right)$ we have $\widehat{G}_{n} \in V L$ with $\widehat{G}_{0}^{S} \subseteq \widehat{G}_{n}^{S}=G_{S} \in V L_{S}$ and $\widehat{G}_{n}^{T}=G_{T} \in V L_{T}$.

Proof. From Fact 1 it follows, that each BC-model transformation sequence $\left(G_{S}, \widehat{G}_{0}{\stackrel{t r_{F}^{*}}{ }}_{B C} \widehat{G}_{n}, G_{T}\right)$ with $\widehat{G}_{0}^{S} \subseteq \widehat{G}_{n}^{S}$ can be extended to a model transformation sequence ( $G_{s}, G_{0} \xlongequal{t r_{F}^{*}} G_{n}, G_{T}$ ) with $G_{n}=\widehat{G}_{n}$. The completeness of model transformations implies for the second sequence $G_{S} \in V L_{S}$, $G_{T} \in V L_{T}$ and $G_{n} \in V L$. Now $G_{n}=\widehat{G}_{n} \in V L, \widehat{G}_{0}^{S} \subseteq \widehat{G}_{n}^{S}=G_{n}^{S}=G_{S} \in V L_{S}$ and $\widehat{G}_{n}^{T}=G_{n}^{T}=G_{T} \in V L_{T}$ which implies correctness of the BC-model transformation.

Finally we show how to propagate a partially MT-consistent source constraint (see Fig. 6) to MT-consistent target constraint as shown already in Fig. 4 using the BC-model transformations in Def. 5. Intuitively a partially MT-consistent source constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ is a source constraint such that we have a BC-model transformation sequence from $\left(P^{S} \leftarrow \emptyset \rightarrow \emptyset\right)$ to $\widehat{P}$ and from $\left(C^{S} \leftarrow \emptyset \rightarrow \emptyset\right)$ to $\widehat{C}$ leading to a propagated integrated constraint $P C(\widehat{a}: \widehat{P} \rightarrow \widehat{C})$ together with a corresponding propagated source constraint $P C\left(\widehat{a}^{S}: \widehat{P}^{S} \rightarrow \widehat{C}^{S}\right)$ and target constraint $P C\left(\widehat{a}^{T}: \widehat{P}^{T} \rightarrow \widehat{C}^{T}\right)$

Definition 6 (Partially MT-Consistent Source Constraint). A source constraint $P C\left(a^{S}\right)$ with $a^{S}: P^{S} \rightarrow C^{S}$ is called partially MT-consistent if there exist BC-model transformation sequences $\widehat{P}_{0} \xlongequal{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{P}_{l}, \widehat{C}_{0} \xlongequal{\operatorname{tr}_{F}^{*}}{ }_{B C}$ $\widehat{C}_{l} \xrightarrow{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{C}_{n}$ as shown below leading to a morphism $\widehat{a}=\operatorname{trace}\left(\operatorname{tr}_{F}^{\prime *}\right) \circ \widehat{a}_{l}$, such that the diagram below commutes and we have $\widehat{P}^{S}, \widehat{C}^{S} \in \mathcal{L}_{S}$ :

Moreover, $P C(\widehat{a}: \widehat{P} \rightarrow \widehat{C})$ is called propagated integrated constraint, $P C\left(\widehat{a}^{S}\right.$ :
$\left.\widehat{P}^{S} \rightarrow \widehat{C}^{S}\right)$ propagated source constraint, and $P C\left(\widehat{a}^{T}: \widehat{P}^{T} \rightarrow \widehat{C}^{T}\right)$ propagated target constraint, where $\widehat{a}^{S}$ and $\widehat{a}^{T}$ are the source and target components of $\widehat{a}$.

This allows us to present our second main result - the validity of propagation of partially MT-consistent source constraints - as a generalisation of Thm. 2.

Theorem 3 (Propagation of Partially $M T$-consistent Source Constraints). Given a propagation consistent model transformation MT and a partially MT-consistent source constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$, then we have MT-consistent propagated constraints $P C(\widehat{a}: \widehat{P} \rightarrow \widehat{C})$ with $P C\left(\widehat{a}^{S}\right)$ and $P C\left(\widehat{a}^{T}\right)$. If $\widehat{P}$ is admissable, then we have for all $G^{S} \in \mathcal{L}_{S}$ with model transformation sequence $\left(G^{S}, G_{0} \xrightarrow{t r_{F}^{*}} G, G^{T}\right)$ :

$$
\left(G^{S} \models P C\left(\widehat{a}^{S}\right)\right) \Rightarrow\left(G \models P C(\widehat{a}) \wedge G^{T} \models^{w} P C\left(\widehat{a}^{T}\right)\right) .
$$

Proof. First we show that for each partial MT-consistent source graph constraint $P C\left(a^{S}: P^{S} \rightarrow C^{S}\right)$ the propagated constraints $P C(\widehat{a}: \widehat{P} \rightarrow \widehat{C})$, $P C\left(\widehat{a}^{S}: \widehat{P}^{S} \rightarrow \widehat{C}^{S}\right)$, and $P C\left(\widehat{a}^{T}: \widehat{P}^{T} \rightarrow \widehat{C}^{T}\right)$ are MT-consistent:

By Def. 6 we have BC-model transformation sequences $\widehat{P}_{0} \xlongequal{\operatorname{tr}_{F}^{*}}{ }_{B C} \widehat{P}_{l}=\widehat{P}$ and $\widehat{C}_{0} \xrightarrow{t r_{r}^{*}}{ }_{B C} \widehat{C}_{l} \xrightarrow{\operatorname{tr}_{F}^{\prime \prime}}{ }_{B C} \widehat{C}_{n}=\widehat{C}$ which implies $\widehat{P}, \widehat{C} \in V L$ by correctness of BC-model transformation in Fact 2. This implies $\widehat{P}^{T}, \widehat{C}^{T} \in V L_{T}$ and by assumption $\widehat{P}^{S}, \widehat{C}^{S} \in \mathcal{L}_{S} \subseteq V L_{S}$. Hence we have $M T$ - consistency of $P C(\widehat{a}: \widehat{P} \rightarrow \widehat{C}), P C\left(\widehat{a}^{S}: \widehat{P}^{S} \rightarrow \widehat{C}^{S}\right)$, and $P C\left(\widehat{a}^{T}: \widehat{P}^{T} \rightarrow \widehat{C}^{T}\right)$. This allows to apply Thm 2 .

Figure 8: Source constraint and propagated constraint

Example 6 (Propagation of a Partially $M T$-consistent Source Constraint). The constraint publicIsEncrypted2 in Fig. 8 is a partial model, as shown in Fig. 6. Therefore there is no total match from the left-hand-side of the rule $L$ to $P$, but only a partial match $m^{-}$. This leads to the injective span $(L \stackrel{d}{\leftarrow} D \xrightarrow{m} G)$ with $D$ being the domain of $m^{-}$. With a pushout over $D$ the black bullet nodes are "borrowed" from $L$ and a standard triple graph transformation over the rule can be performed. After this step the premise graph is already completely translated and the conclusion graph can be translated as seen in Fig. 4.

## 5 Related Work and Conclusion

Model transformation is an important concept in order to establish a consistent relationship between source and target models, like business and IT models in enterprise modelling [2]. Security constraints can be defined separately for source and/or target models, but up to now, it is an open problem how to establish a consistent relationship between source and target constraints.

Triple graph grammars have been successfully applied in several case studies for bidirectional model transformations, integrations and synchronizations [15, 12, 16, 10, and there are a variety of formal results concerning correctness, completeness and termination [5], functional behaviour and optimization with respect to the efficiency of their execution [11.

Previous studies on the relationship between model transformations and constraints focussed on general properties, e.g. in order to provide techniques for the verification and validation of model transformations [9, 1, 3] in order to detect underspecified parts or mismatches to the requirements of the domain. They perform semi-automated reasoning using e.g. the theorem prover Isabelle/HOL [9], Prolog [1] or they use OCL validation tools [3]. In contrast to them, this paper has its main focus on a constructive approach for the translation of domain and model specific source into target constraints, i.e. those properties of a source model which are usually not valid for all models of the source language.

Given a model transformation $M T$ based on triple graph grammars, we have defined in this paper $M T$-consistent constraints and shown how to propagate source constraints to integrated and target constraints. In our first main result, we prove that under suitable conditions this propagation is consistent in the sense that validity of the source constraint for the source model implies validity of the integrated and target constraint for the integrated resp. target model. Since constraints are often incomplete models we study
in Sec. 4 also the propagation of partial $M T$-consistent source constraints leading to our second main result. For this purpose we provide a new concept of model transformations with borrowed context, which allows to transform also model fragments. Transformations of model fragments along total matches are considered for the case of plain graph transformations already in [7] for the refactoring of rules. Based on the new theory of model transformations with borrowed context [13] we will also propagate other kinds of model fragments in future work, e.g. rules of the operational semantics from source to target models in order to prove semantical correctness of model transformations.
