Running title: Regulation of von Willebrand Factor basolateral secretion

Summary statement

Changes in RGS4 expression alter levels of subendothelial, matrix-associated VWF, affecting platelet recruitment in a model of endothelial damage. This introduces a novel control over VWF function.

Abstract

The haemostatic protein von Willebrand Factor (VWF) exists in plasma and subendothelial pools; the former secreted from endothelial storage granules, Weibel-Palade bodies (WPBs), by basal secretion with a contribution from agonist-stimulated secretion, the latter secreted into the subendothelial matrix by a constitutive pathway, not involving WPBs. We set out to determine if the constitutive release of subendothelial VWF is actually regulated and if so, what functional consequences this might have.

Constitutive VWF secretion can be increased by a range of factors; changes in VWF expression, levels of TNF-alpha or other environmental cues. An RNAseq analysis revealed that expression of RGS4 (Regulator of G protein signalling 4) was reduced in endothelial cells (HUVECs) grown under these conditions. si-RGS4 treatment of HUVECs increased constitutive basolateral secretion of VWF, probably by affecting the anterograde secretory pathway. In a simple model of endothelial damage we show that RGS4-silenced cells increased platelet recruitment onto the subendothelial matrix under flow. These results show that changes in RGS4 expression alter levels of subendothelial VWF, affecting platelet recruitment. This introduces a novel control over VWF function.

Keywords: Weibel-Palade bodies; von Willebrand Factor; extracellular matrix; RGS4; constitutive secretion

Introduction

Endothelial Von Willebrand factor (VWF) plays several roles in haemostasis. This reflects not only its central role as a mechanosensitive binding platform for platelets, but also its presence in three secreted pools. VWF stored in Weibel-Palade bodies can be released either by localised agonist-stimulated exocytosis, to provide transient VWF strings on the endothelial surface that initiate primary haemostasis, or by general basal secretion, to provide the large pool of circulating plasma VWF (Lopes da Silva and Cutler, 2016). The third VWF pool is released by constitutive secretion into the subendothelial matrix where it presumably acts in platelet recruitment following exposure by injury.

This latter pool of VWF is the least well understood. We previously reported that it comprises very poorly multimerised VWF, not stored in Weibel-Palade bodies but secreted by a constitutive pathway targeted to the subendothelial space where it likely binds to the extracellular matrix (Lopes da Silva and Cutler, 2016). Both the regulation of this pathway and a direct analysis of the function of this VWF after delivery remain elusive. We used RNAseq to analyse cells treated with different regimes that increased constitutive VWF secretion, allowing the identification of Regulator of G protein signalling 4 (RGS4) as a commonly downregulated mRNA and as a candidate modulator of this constitutive pathway. RGS4 is known to act both as a GTPase activating (GAP) protein (Watson et al., 1996, Berman et al., 1996) and can also bind to β' COP (also known as COPB2) (Sullivan et al., 2000), a component of the machinery underpinning the retrograde secretory pathway. Both of these functions could potentially modulate a constitutive secretory pathway. We used RGS4 siRNA to show that this protein does indeed regulate constitutive secretion of VWF to the subendothelial side, and developed an assay mimicking endothelial damage, by stripping endothelial cells from their extracellular matrix, to determine the effects on platelet recruitment under flow of changing levels of RGS4. We conclude that altering the amount of constitutively secreted VWF into the subendothelial space by decreasing RGS4 levels in endothelial cells can indeed alter platelet recruitment to an exposed subendothelial surface in a simplified model of injury.

Results

Identification of a candidate for control of VWF constitutive secretion in ECs

To identify regulators of constitutive VWF secretion we challenged human umbilical vein endothelial cells (HUVECs) with conditions known to increase unregulated (i.e. basal plus constitutive) VWF secretion. We used BFA treatment to distinguish between basal and constitutive secretion (Giblin et al., 2008, Lopes da Silva and Cutler, 2016); BFA selectively blocks constitutive secretion by disrupting endoplasmic reticulum (ER) to Golgi transport, thus preventing exit of newly synthesized material from the ER without affecting secretion from post-Golgi organelles such as WPBs (including basal secretion of VWF) (Fig. 1A). The conditions that we tested, shown in the referenced literature to increase unregulated VWF secretion, were: i) VWF knock down (KD) by siRNA (Ferraro et al., 2014); ii) nocodazole treatment (Ferraro et al., 2014); iii) TNF α treatment (Bernardo et al., 2004, van der Poll et al., 1992); iv), MyRIP KD (Bierings et al., 2012, Nightingale et al., 2009), v), GRK2 KD (Stevenson et al., 2014), vi) EBM2 medium (from our unpublished observation). We also used AP1 KD as a positive

control for the maximum possible constitutive output that could be obtained by switching all VWF secretion to constitutive: AP1 is essential for WPB formation, and once ablated, the major VWF secretory pathways (basal and agonist-stimulated) are redirected towards the constitutive pathway (Lui-Roberts et al., 2005, Lopes da Silva and Cutler, 2016). These experiments (Fig. 1B-H) showed that - besides AP1 depletion - suppressing VWF levels, treating with TNF α , or growth in EBM2 medium, all increased constitutive VWF release, while the other treatments only affected basal release.

To identify common factors among the three treatments we used an RNAseq approach (Table 1-3 in the Data Supplement). No genes were found commonly upregulated in the three conditions, but two genes - Regulator of G protein signalling 4 (RGS4) and Gap junction protein 5 (GJA5) - were downregulated in si-VWF, TNF α and EBM2 (Fig. 2A,B). Since RGS4 is a cytosolic protein, already shown to be involved in negatively regulating agonist/receptor- stimulated secretion of insulin (Ruiz de Azua et al., 2010) and catecholamines (Iankova et al., 2008) we further investigated its role in VWF constitutive secretion. We first confirmed by qPCR that RGS4 mRNA was downregulated in all three conditions (Fig. 2C), but not when constitutive secretion was not affected, i.e. in nocodazole treatment, MyRIP KD, GRK2 KD and AP1 KD (Fig. 2D). Interestingly, while AP1 KD does increase constitutive secretion of VWF, it does not decrease RGS4 expression, whereas when RGS4 expression is decreased in TNF α , EBM2, VWF KD, we did not find changes in AP1 expression (Fig. 2D and Table 1-3 in the Data Supplement), suggesting that AP1 and RGS4 act through different mechanisms. Since we were not able to measure RGS4 by immunoblot using commercial antibodies, we used an indirect approach to check whether the phenotype we observed upon decreased RGS4 mRNA expression with the different treatments was due to a consequent diminished amount of RGS4 protein. We treated the cells with a NO donor (CysNO), known to induce RGS4 proteasomal degradation(Jaba et al., 2013, Hu et al., 2005), and then measured VWF secretion compared to control Cys. We noticed an increase in unstimulated VWF secretion in cells treated with CysNO (Fig. 2E), and this prompted us to conclude that the treatments causing increased unstimulated VWF secretion also affected general RGS4 expression, not just its mRNA.

RGS4 KD increases VWF constitutive secretion from the basolateral side of ECs

To verify that the decreased expression of RGS4 was directly responsible for increasing VWF constitutive secretion we used an siRNA approach (Fig. 3A). si-RGS4 affected neither the length distribution nor the number of WPBs (Fig. 3B,C), but it increased constitutive VWF secretion about two-fold (Fig. 3D). To analyse any effect on the polarity of secretion we seeded the HUVECs in transwells and collected the medium from the top well (releasate from the apical side) and the bottom

well (releasate from the basolateral side) (Fig. 3E). This revealed that the increase in VWF secretion upon si-RGS4 was mostly from the basolateral surface of the cells and was indeed constitutive, since it was blocked by BFA (Fig. 3F). To test if this effect of RGS4 KD was specific to VWF secretion, we transfected the cells with a lumGFP construct (Blum et al., 2000, Knipe et al., 2010), a cargo known to be secreted constitutively in ECs but in a non-polarised way (Lopes da Silva and Cutler, 2016). RGS4 did not affect either the amount or polarity of lumGFP secretion, suggesting that its action is at least partly specific to VWF (Fig. 3G). These data indicate that RGS4 negatively regulates the basolateral secretion of VWF from endothelial cells.

The COPB2 binding activity of RGS4 is responsible for VWF constitutive secretion

RGS4 is known to have at least two activities: to act as a GTPase activating protein (GAP) for heterotrimeric G proteins and to bind β' -COP (COPB2), a subunit of the COPI coatomer complex essential to retrograde transport from the trans-Golgi network to the cis-Golgi network and endoplasmic reticulum (Sullivan et al., 2000). In principle, either activity could affect constitutive secretion; heterotrimeric G-proteins are active at the Golgi (Giannotta et al., 2012, Cancino et al., 2014), and we have recently shown that modulating retrograde trafficking that is dependent on COP1-coated vesicle transport can affect exit from both the ER and from the TGN (Lopes-da-Silva et al., 2019). To test if RGS4 depletion affects G-protein signalling or binding β' -COP we overexpressed (OE) a GAP-dead RGS4 mutant (“N128A”) (Fig. 4A), or an RGS4 mutant with deleted (“delta 131-205”) (Fig. 4B) or mutated (“K100E”) (Fig. 4C) binding site for β' -COP. When over-expressed in identical circumstances, the GAP-dead construct had no effect on unstimulated VWF secretion, but the constructs unable to bind β' -COP were able to replicate the phenotype observed upon RGS4 depletion. These experiments suggest that RGS4 may indeed act as an indirect brake on constitutive secretion of VWF from HUVECs by interfering with the retrograde trafficking pathway that recycles machinery for re-use by the anterograde constitutive pathway.

The functional activity of VWF delivered to the subendothelial matrix is regulated by RGS4.

Our data provide evidence that RGS4 controls constitutive basolateral secretion of VWF. Since this pool of VWF is released into the subendothelial matrix and is only in contact with circulating blood when there is an injury compromising the endothelial layer, we sought to determine the functional significance of this poorly characterised pool of VWF. We therefore designed an experiment to mimic injury that would result in exposure of the subendothelial matrix to platelets under flow. We plated

si-RGS4 or control HUVECs in flow chambers, allowed them to grow to confluence, then removed the cells under flow, and passed whole blood or platelets over the exposed subendothelial matrix. After fixation and antibody labelling of VWF, we quantified by immunofluorescence microscopy both that RGS4 KD did lead to more VWF being present within the matrix (Fig. 5A), and that there was increased platelet recruitment (shown by the marker CD41), either from whole blood (Fig. 5B,C) or isolated platelets (Fig. 5D). Taken together, this suggests that by regulating secretion of VWF into the subendothelial space, RGS4 can potentially control the ability of an endothelium-denuded surface such as an injured vessel wall to recruit platelets to the injury-exposed matrix.

Discussion

VWF is released from endothelial cells into three pools, of which that located within the subendothelial matrix has only recently been at all characterised. In this work we show that the secretion of this pool of VWF is regulated, affecting the recruitment of platelets when exposed.

We previously showed that not only is this pool of VWF targeted for release towards the subendothelial space, but is constitutively secreted i.e. not stored within WPB, and thus cannot undergo the complex biogenesis of the rest of VWF. It largely remains as dimers, not forming the ultra-large concatamers that are generated within the TGN/WPB (Lopes da Silva and Cutler, 2016). This pool is not only of much lower molecular weight but also does not form the coils that support multimerization, characteristic of lumenally secreted VWF. It is not likely to be stretched under flow to optimise its ability to recruit platelets, but rather may bind to elements such as collagen within the matrix, potentially even saturating available VWF-binding sites (although under our standard growth conditions, this seems not to be the case). Nevertheless, VWF bound to the extracellular matrix was shown to be able to bind to platelets under flow (Baruch et al., 1991, Stel et al., 1985, Sixma et al., 1987, Houdijk et al., 1986). Here we have found that the constitutive release of VWF into this pool can be controlled by RGS4, a poorly characterised protein with two previously identified functions. Our experiments showed that this protein acts to modulate the constitutive secretion of VWF, likely via its ability to bind to β' COP. β' COP is essential to forming COP1 coats that support retrograde vesicular transport from the TGN all the way back to the ER. Interfering with retrograde transport, e.g. by suppressing GBF1 that controls COP1 coat assembly by Arfs1&4, leads to modulation of VWF anterograde traffic as well (Lopes-da-Silva et al., 2019). In that study, we also reported dramatic effects on WPB formation at the TGN. Inhibiting retrograde traffic reduced recycling of components essential to anterograde trafficking, causing hold-ups at ER and TGN exit, the latter leading to the formation of giant WPB. Here, we speculate that by removing RGS4, we are promoting retrograde and

anterograde trafficking, hence also constitutive VWF trafficking, without significantly affecting WPB size.

Binding of RGS4 to β' COP was shown to prevent COPI binding to purified Golgi membranes and to impair constitutive trafficking of aquaporin in LLC-PK1 cells (Sullivan et al., 2000). Consistent with this, we show that RGS4 depletion, or overexpression of RGS4 lacking the ability to bind β' COP, caused an increase in constitutive VWF secretion to the subendothelial side of endothelial cells, arguably by removing the brake on β' COP and promoting β' COP function in retrograde/anterograde trafficking. How specific to VWF this mechanism might be remains to be elucidated. Our experiments suggest that in HUVECs, RGS4 KD specifically increases VWF constitutive secretion, but more sensitive approaches (e.g. using proteomics) could be used to fully address this question.

Is this mechanism likely to be used for physiological control? One possible mechanism would involve nitrous oxide (NO), a promoter of a healthy, anti-atherogenic endothelial phenotype, also able to trigger the proteasomal degradation of RGS4 (Jaba et al., 2013, Hu et al., 2005). We speculate that when NO is induced, it will increase the secretion of VWF towards the subendothelial space, but not towards the vessel lumen into the plasma VWF pool. In this way NO will not drive the formation of a plug that could become a thrombus, because the subendothelial VWF will only become exposed when damage has already occurred. The well-known anti-platelet actions of NO can thus act in the lumen of the vessel without jeopardising a VWF-dependent haemostatic response to actual injuries that expose VWF in the subendothelial space.

This work focusses on the neglected constitutive pool of VWF that not only has a different mode of biosynthesis from the better understood WPB-associated pools, but it is also differentially targeted for secretion to the subendothelial space, and at least in part regulated by separate machinery, depending on RGS4. Further details of all the mechanisms involved in the control of this pool, which to date was believed to have little/no control, plus the functional consequences of its regulation now clearly warrant future investigation.

Materials and Methods

Cell culture

Human umbilical vein endothelial cells (HUVECs) pooled from multiple donors are from PromoCell and used within the fifth passage. Cells were cultured in M199 (Thermo Fisher Scientific, UK) or EBM2 (Promocell, Heidelberg, Germany) with 20% foetal bovine serum (Labtech, Heathfield, UK), 30 μ g/ml endothelial cell growth supplement from bovine neural tissue (Sigma-Aldrich, UK) and 10 U/ml heparin.

Nocodazole 1 µg/mL, TNF α (50ng/ml) were from Sigma-Aldrich, UK. Nocodazole and TNF α treatment were for 16 and 24 hours respectively.

siRNA transfection

We used an AMAXA Nucleofector (Lonza, Basel, Switzerland) to nucleofect siRNAs into 1×10^6 cells using two rounds of nucleofection, two days apart. After the second nucleofection, cells were seeded into a 12 well or transwell plate at a density of 1.2×10^5 cells per well to be fully confluent at assay 48h later. The siRNAs were custom synthesised by Eurofins Genomics (Ebersberg, Germany). The target sequences are:

- si-Luciferase (ctl): CGUACGCGGAAUACUUCGA
- si-RGS4 (pool of two oligos, 250 pmol each): CCUCAAGUCUCGAUUCUAU and GAAGGGAGCCAAGAGUUCA
- si-MYRIP (pool of two oligos, 250pmol each): GAUGAGAUGGGCUCCGAUA and GAUAUUGAGAGCCGGAUUU
- si-GRK2 (pool of two oligos, 150pmol each): UGUCCAGUAACUUGAUUCC and GCUCGCAUCCCUUCUCGAAUU
- si-AP1 (short for si-AP1M1, 300pmol): AAGGCAUCAAGUAUCGGAAGA
- si-VWF (200pmol): GGGCUCGAGUGUACCAAAA

Plasmids

p-MYC-HIS-RGS4 and pMYC-HIS-RGS4(131-205), pCEFL-RGS4, pCEFL-RGS4 N128A were generously gifted by Dr. Kirk Druey. pMYC-HIS-RGS4-K100E was generated from p-MYC-HIS-RGS4 by using the Q5 site directed mutagenesis kit (New England BioLabs, Herts, UK). LumGFP plasmid is described here (Blum et al., 2000). Plasmids were nucleofected ($2 \mu\text{g}$ or $10 \mu\text{g}$ for lumGFP) into 1×10^6 cells and cells were seeded into 12 well plate or transwell plate at a density of 1.2×10^5 cells per well to be fully confluent and assayed 48h later. When plasmids were nucleofected with siRNAs, they were added at the second round of nucleofection.

VWF secretion assay

Confluent cells were washed in serum-free (SF) medium (M199, 0.1 mg/mL bovine serum albumin (BSA), 10 mmol l $^{-1}$ HEPES-NaOH, pH 7.4) and then incubated in SF medium for 1 hour at 37°C. The medium was collected and the cells were then lysed to determine VWF levels in both samples (releasate and lysate). Brefeldin A (BFA, 5 µmol l $^{-1}$ from Sigma) was added to the cells 1 hour before the assay and then present throughout the experiment. For the NO donor experiment, CysNO or

control Cys, freshly prepared according to (Cook et al., 1996) and (Smith et al., 2018), were added to SF medium at the final concentration of 200 µmol l⁻¹ to treat confluent cells. Medium was collected and cells were lysed after 1 hour incubation at 37°C.

Relative amounts of VWF were determined by sandwich enzyme-linked immunosorbent assay (ELISA) as previously described (Ferraro et al., 2016).

Transwell experiments

Cells were seeded at 1.2x10⁵ cells per well onto transwell devices (cat#3460 Corning, Flintshire, UK), and assayed for secretion assay two days after, by measuring the amount of VWF in both the apical (top well) and basolateral chamber (bottom well).

lumGFP secretion assay

Cells nucleofected with lumGFP plasmid (Blum et al., 2000, Knipe et al., 2010) and seeded on transwells were analysed two days after nucleofection. LumGFP secretion assay was performed as VWF secretion assay, as previously described (Lopes da Silva and Cutler, 2016). Relative amounts of GFP were determined by sandwich ELISA using MaxiSorp plates (Thermo Fisher Scientific) coated with sheep anti-GFP (1:50,000 cat# 4745-1051, BioRad, Watford, UK), followed by blocking and incubation with samples. Plates were washed and incubated with rabbit anti-GFP (1:20,000, cat# A6455, Thermo Fisher Scientific) followed by washing and a final incubation with goat anti-Rabbit conjugated with horseradish peroxidase (HRP) (1:3000, cat# AB_2307391 Jackson Laboratories). Plates were developed with o-phenylenediamine dihydrochloride and hydrogen peroxide in a citrate phosphate buffer. Absorbance was analysed at 450 nm in a Thermomax microplate reader (Molecular Devices, San Jose, CA, US) using a kinetic protocol with a reading every 30 s for 30 min. A standard curve was made using a lumGFP nucleofected lysates serially diluted. Results are shown as percentage of secreted GFP from the total GFP (secreted plus lysate) measured in each sample.

RNA extraction, qPCR and RNAseq

RNA was extracted using the RNeasy kit (Qiagen, Manchester, UK), retrotranscribed into cDNAs by using the SuperScript III first-strand synthesis system (Thermo Fisher Scientific) and amplified using SYBR Green (DyNAamo SYBR Green qPCR Kit, Thermo Fisher Scientific) on a CFX ConnectTM Real-Time PCR Detection System (BioRad, Watford, UK).

RNAseq was performed as described in (Lopes-da-Silva et al., 2019). The RNAseq raw and processed data were deposited on NCBI GEO under accession code GSE151854, (<https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE151854>).

Decellularisation and flow assay

We grew cells in Ibidi μ -slides VI (cat. # IB-80606, ThistleScientific, Glasgow, UK) until they were fully confluent. We then attached the slide to a pump system (Harvard Apparatus, Holliston, MA, USA) maintained at 37 °C onto a Zeiss Axiovert 100 inverted microscope (Artisan Technology Group, Champaign, IL, US). The cells were initially superfused with PBS using a constant wall shear stress of 2.5 dynes/cm² (0.25 MPa, 1.4ml/min), that was maintained throughout the experiment. After 1 minute the cells were superfused with NH₄OH 50 mmol l⁻¹ and Triton X-100 0.1% in PBS for 2 minutes (the decellularisation solution was adapted from (Sixma et al., 1987) and (Franco-Barraza et al., 2016)), during which we could observe the cells detaching in real time. We then superfused again with PBS, followed by either whole blood or platelets (1x10⁸/ml) in Tyrode buffer for 1 minute. After a final perfusion with PBS, μ -slides were fixed under reduced flow (0.7 ml/min) with 4% formaldehyde for 5 minutes. The μ -slides were fixed for a further 5 minutes under static conditions, washed with PBS and then processed for confocal immunofluorescence.

Blood and platelets

Blood (7ml) was drawn from local volunteers into citrate tubes and utilised within few hours. The relevant UK research ethics committee approved the work and the participant gave their written informed consent. Platelets were spare pooled platelets from the London transfusion service of the NHS.

Immunofluorescence and confocal microscopy

After fixation of the decellularised matrix, we incubated the slides with 5% BSA diluted in PBS for 30 minutes. Samples were subsequently incubated with primary antibodies diluted in 1% BSA in PBS for 1 hour. Antibodies used were: anti-VWF (1:1000) (cat. No A00A2, from Agilent DAKO, Stockport, UK), anti-CD41-FITC (1:200) (clone 5B12, FCMAB195F, from Millipore, Dorset, UK). Secondary antibodies: AlexaFluor 488, 564 and 647 (Thermo Fisher Scientific) at 1:500 dilution with PBS. Hoechst 33342 (Thermo Fisher Scientific) was used to counterstain nuclei (1: 10,000). Images were acquired using a spinning disc Ultraview Vox confocal microscope (PerkinElmer, Waltham, MA, US) with a 20x objective and 1.5x tube lens.

Statistical analysis

Statistical analyses were performed using GraphPad Prism software version 7. All graphs are represented as mean (horizontal bar) \pm S.D. Statistical significance was assessed using two-tailed unpaired Student's t test or one-way ANOVA.

Legends

Figure 1. Conditions increasing VWF constitutive secretion in ECs. To measure and distinguish between basal and constitutive VWF secretion we deployed brefeldin A (BFA), a drug able to block constitutive secretion without affecting the release of pre-formed VWF-containing organelles (WPBs) via basal release (A). HUVECs were challenged with the indicated conditions known to increase unstimulated VWF secretion: VWF KD (si-VWF, B), nocodazole (C), TNF α (D), MyRIP KD (si-MyRIP, E), GRK2 KD (si-GRK2, F), EBM2 medium (G), AP1 KD (si-AP1, H). The amount of secreted VWF (in the absence of any stimulant) was measured by ELISA and plotted as a % of the total VWF in cells. Conditions A, C, F were further investigated because they induced an increase in constitutive secretion vs basal secretion, since that increase was blocked by BFA.

In A-G, a representative experiment with mean and S.D. is shown from N = 3 independent experiments. Student's t test was performed, *p ≤ 0.05, **p ≤ 0.01, ***p ≤ 0.001, n.s. = not significant.

Figure 2. Identification of a regulator of VWF constitutive secretion in ECs. The comparison of the transcriptome (made by RNAseq) of the previously selected conditions (si-VWF, EBM2, TNF α) relative to their respective controls enabled us to identify a putative regulator of VWF constitutive secretion. The Venn diagrams show the number of down-regulated (A) and up-regulated transcripts (B). RGS4 and GJA5 were the only transcripts found significantly regulated (under-expressed) upon all three treatments (A,C), while in the other treatments where constitutive secretion was not affected (GRK2 KD and MyRIP KD) or in AP1 KD (an independent regulator of constitutive secretion), RGS4 mRNA was upregulated (D), as measured by qPCR. In C,D, a representative experiment with mean and S.D. is

shown from N = 2 independent experiments. One-way ANOVA with Dunnett's multiple comparisons test, ****p < 0.0001.

A NO donor (CysNO), which affects RGS4 at the protein level, triggering its degradation, increases unstimulated VWF secretion compared to the Cys control (E). A representative experiment with mean and S.D. is shown from N = 3 independent experiments. Student's t test was performed, *p ≤ 0.05.

Figure 3. RGS4 KD increases VWF constitutive secretion from the basolateral side of ECs. We successfully reduced RGS4mRNA in HUVEC with siRNAs (A). A representative experiment with mean and S.D. is shown from N = 4 independent experiments. Student's t test was performed, ****p < 0.0001. By doing high throughput imaging we did not observe changes in the length of WPBs (the area covered by the longer WPBs, those greater than 2 μ m, is used as a proxy for length) in the RGS4 KD cells (B), or in the number of WPBs per cell (C), n = 8 wells, for each well the mean of 9 fields of view were analysed. Student's t test, n.s.= not significant. We did measure, by secretion assay followed by ELISA, an increase in constitutive VWF secretion (D). The plot shows means and S.D. of a representative experiment from N = 3 independent experiments. Student's t test, ***p ≤ 0.001.

Plating cells in transwells (E-G) enabled us to better dissect the route of the increased constitutive VWF secretion upon si-RGS4 (F), which was mainly released towards the basolateral side of the ECs. Using a construct expressing a constitutively secreted protein (lumGFP) we did not measure changes in its secretion upon si-RGS4 (G). In F,G a representative experiment with mean and S.D. is shown from N = 3 independent experiments. Student's t test was performed, ***p ≤ 0.001, n.s.= not significant.

Figure 4. The COPB2 binding activity of RGS4 is responsible for VWF constitutive secretion. To understand which of the two known functions of RGS4 is responsible for controlling constitutive VWF secretion we expressed and compared the effects of mutated and wt RGS4 constructs. Expressing a GAP dead mutant (N128A) does not change the amount of unstimulated VWF secretion (A), whereas expressing a construct lacking the binding site for COPB2 (delta 131-205) or mutated in the β' COP binding activity (K100E) results in an increase in unstimulated VWF secretion (B,C). A representative experiment with mean and S.D. is shown from N = 3 independent experiments. Student's t test was performed, ***p ≤ 0.001, *p ≤ 0.05, n.s.= not significant.

Figure 5. Constitutive basolateral VWF secretion provides a functional pool of VWF in the subendothelial space. The removal of ECs exposed the subendothelial matrix and the VWF bound to

it. Upon decellularisation, more VWF is bound to the extracellular matrix in RGS4 KD cells (A,B). Scatter plots present mean and SD of a representative experiments of N=3 independent experiments. Each symbol is the VWF fluorescence intensity (integrated density) of a field of view. Student's t test was performed, ***p < 0.0001. Confocal microscopy shows VWF (magenta) and platelets (green). Scalebar is 50 µm (B). When we superfused whole blood (B,C) or isolated platelets (D) over the decellularised matrix we could see more platelets adherent in the RGS4 KD compared to control. In C,D a representative experiment with mean and S.D. is shown from N = 3 independent experiments. Each symbol represents the area covered by platelets (n=35 fields of view). Student's t test was performed, ***p < 0.0001.

Legends

Table 1. List of up- and down-regulated genes in cells untreated (mock) or treated with siRNA against VWF (si-VWF), as measured by RNAseq. Statistical significance was tested by ANOVA. p-values and fold changes are shown.

Table 2. List of up- and down-regulated genes in cells untreated (ctl) or treated with TNFalpha as measured by RNAseq. Statistical significance was tested by ANOVA. p-values and fold changes are shown.

Table 3. List of up and down-regulated genes in cells grown in M199 compared to EBM2 medium as measured by RNAseq. Statistical significance was tested by ANOVA. p-values and fold changes are shown.

Table 1. List of up- and down-regulated genes in cells untreated (mock) or treated with siRNA against VWF as measured by RNAseq
