#### Abstract

A companion of Ostrowski＇s inequality for functions of bounded variation and applications are given． Keywords：Ostrowski＇s Inequality，Trapezoid Rule，Midpoint Rule． 2000 MSC：26D15，41A55．

## 1．Introduction

In［11］，the author has proved the following inequality of Ostrowski type［24］for functions of bounded variation．
Theorem 1．1．Let $f:[a, b] \rightarrow \mathbb{R}$ be a function of bounded variation on $[a, b]$ ．Denote by $\bigvee_{a}^{b}(f)$ its total variation on $[a, b]$ ．Then，for any $x \in[a, b]$ ，one has the inequality：

$$
\begin{equation*}
\left|f(x)-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq\left[\frac{1}{2}+\left|\frac{x-\frac{a+b}{2}}{b-a}\right|\right] \bigvee_{a}^{b}(f) \tag{1.1}
\end{equation*}
$$

The constant $\frac{1}{2}$ is best possible in the sense that it cannot be replaced by a smaller quantity．
The above inequality（1．1）has as a remarkable particular case，the mid－point inequality，namely

$$
\left|f\left(\frac{a+b}{2}\right)-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{2} \bigvee_{a}^{b}(f)
$$

Here $\frac{1}{2}$ is a best constant as well．
The corresponding version for the generalized trapezoid inequality was obtained in［4］．

[^0]Theorem 1.2. With the assumptions in Theorem 1.1, one has the inequality

$$
\begin{equation*}
\left|\frac{(x-a) f(a)+(b-x) f(b)}{b-a}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq\left[\frac{1}{2}+\left|\frac{x-\frac{a+b}{2}}{b-a}\right|\right] \bigvee_{a}^{b}(f) \tag{1.2}
\end{equation*}
$$

for any $x \in[a, b]$.
Here the constant $\frac{1}{2}$ is also best possible.
The trapezoid inequality

$$
\left|\frac{f(a)+f(b)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{2} \bigvee_{a}^{b}(f)
$$

is the best inequality one can derive from 1.2 . Here the constant $\frac{1}{2}$ is also sharp.
Recently, Guessab and Schmeisser [23, in the effort of incorporating together the mid-point and trapezoid inequality, have proved amongst others, the following companion of Ostrowski's inequality.

Theorem 1.3. Assume that the function $f:[a, b] \rightarrow \mathbb{R}$ is of $H-r$-Hölder type with $r \in(0,1]$, i.e.,

$$
\begin{equation*}
|f(t)-f(s)| \leq H|t-s|^{r} \text { foranyt, } s \in[a, b] \tag{1.3}
\end{equation*}
$$

Then, for each $x \in\left[a, \frac{a+b}{2}\right]$, one has the inequality

$$
\begin{equation*}
\left|\frac{f(x)+f(a+b-x)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq\left[\frac{2^{r+1}(x-a)^{r+1}+(a+b-2 x)^{r+1}}{2^{r}(r+1)(b-a)}\right] H . \tag{1.4}
\end{equation*}
$$

This inequality is sharp for each admissible $x$. Equality is obtained if and only if $f= \pm H f_{*}+c$, with $c \in \mathbb{R}$ and

$$
f_{*}(t)= \begin{cases}(x-t)^{r}, & \text { for } a \leq t \leq x  \tag{1.5}\\ (t-x)^{r}, & \text { for } x \leq t \leq \frac{1}{2}(a+b) \\ f_{*}(a+b-t), & \text { for } \frac{1}{2}(a+b) \leq t \leq b\end{cases}
$$

Remark 1.4. For $r=1$, i.e., $f$ is Lipschitzian with the constant $L>0$, and since

$$
\frac{4(x-a)^{2}+(a+b-2 x)^{2}}{4(b-a)}=\left[\frac{1}{8}+2\left(\frac{x-\frac{3 a+b}{4}}{b-a}\right)^{2}\right](b-a)
$$

then, by (1.4), we get the following companion of Ostrowski's inequality for Lipschitzian functions

$$
\begin{equation*}
\left|\frac{f(x)+f(a+b-x)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq\left[\frac{1}{8}+2\left(\frac{x-\frac{3 a+b}{4}}{b-a}\right)^{2}\right](b-a) L \tag{1.6}
\end{equation*}
$$

for any $x \in\left[a, \frac{a+b}{2}\right]$.
The constant $\frac{1}{8}$ is best possible in (1.6) in the sense that it cannot be replaced by a smaller constant.
By substituting $x=\frac{3 a+b}{4}$ into the above inequality, we obtain the following trapezoid type inequality, which is the best in the class,

$$
\begin{equation*}
\left|\frac{f\left(\frac{3 a+b}{4}\right)+f\left(\frac{a+3 b}{4}\right)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{8}(b-a) L . \tag{1.7}
\end{equation*}
$$

The constant $\frac{1}{8}$ here is also best possible in the above sense.

For a monograph devoted to Ostrowski type inequalities, see [18].
For research papers on Ostrowski's inequality see [1]-[17], [19]-[21] and [22].
The main aim of this paper is to provide a sharp bound for the difference

$$
\frac{f(x)+f(a+b-x)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t,
$$

where $f$ is assumed to be of bounded variation. Some applications for cumulative distribution function and quadrature rules are also given.

## 2. Some Integral Inequalities

The following identity holds.
Lemma 2.1. Assume that the function $f:[a, b] \rightarrow \mathbb{R}$ is of bounded variation on $[a, b]$. Then we have the equality

$$
\begin{align*}
& \frac{1}{2}[f(x)+f(a+b-x)]-\frac{1}{b-a} \int_{a}^{b} f(t) d t  \tag{2.1}\\
& \quad=\frac{1}{b-a}\left[\int_{a}^{x}(t-a) d f(t)+\int_{x}^{a+b-x}\left(t-\frac{a+b}{2}\right) d f(t)+\int_{a+b-x}^{b}(t-b) d f(t)\right]
\end{align*}
$$

for any $x \in\left[a, \frac{a+b}{2}\right]$.
Proof . Obviously, all the Riemann-Stieltjes integrals from the right hand side of (2.1) exist because the functions $(\cdot-a),\left(\cdot-\frac{a+b}{2}\right)$ and $(\cdot-b)$ are continuous on these intervals and $f$ is of bounded variation.

Using the integration by parts formula for Riemann-Stieltjes integrals, we have, for any $x \in$ $\left[a, \frac{a+b}{2}\right]$, that

$$
\begin{gathered}
\int_{a}^{x}(t-a) d f(t)=f(x)(x-a)-\int_{a}^{x} f(t) d t \\
\int_{x}^{a+b-x}\left(t-\frac{a+b}{2}\right) d f(t)=f(a+b-x)\left(\frac{a+b}{2}-x\right)-f(x)\left(x-\frac{a+b}{2}\right)-\int_{x}^{a+b-x} f(t) d t
\end{gathered}
$$

and

$$
\int_{a+b-x}^{b}(t-b) d f(t)=(x-a) f(a+b-x)-\int_{a+b-x}^{b} f(t) d t .
$$

Summing the above equalities we deduce (2.1).
Remark 2.2. A version of this identity for piecewise continuously differentiable functions has been obtained in [23, Lemma 3.2].

The following companion of Ostrowski's inequality holds.
Theorem 2.3. Assume that the function $f:[a, b] \rightarrow \mathbb{R}$ is of bounded variation on $[a, b]$. Then we have the inequalities:

$$
\begin{equation*}
\left|\frac{1}{2}[f(x)+f(a+b-x)]-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \tag{2.2}
\end{equation*}
$$

$$
\begin{aligned}
& \leq \frac{1}{b-a}\left[(x-a) \bigvee_{a}^{x}(f)+\left(\frac{a+b}{2}-x\right) \bigvee_{x}^{a+b-x}(f)+(x-a) \bigvee_{a+b-x}^{b}(f)\right] \\
& \leq\left\{\begin{array}{l}
{\left[14+\left|x-\frac{3 a+b}{4} b-a\right|\right]_{a}^{b}(f)} \\
{\left[2(x-a b-a)^{\alpha}+\left(\frac{a+b}{2}-x b-a\right)^{\alpha}\right]^{\frac{1}{\alpha}}} \\
\times\left[\left[\bigvee_{a}^{x}(f)\right]^{\beta}+\left[\bigvee_{x}^{a+b-x}(f)\right]^{\beta}+\left[\bigvee_{a+b-x}^{b}(f)\right]^{\beta}\right]^{\frac{1}{\beta}}, \text { if } \alpha>1, \frac{1}{\alpha}+\frac{1}{\beta}=1 \text { for any } x \in\left[a, \frac{a+b}{2}\right], \\
{\left[x-a+\frac{b-a}{2} b-a\right] \max \left\{\bigvee_{a}^{x}(f), \bigvee_{x}^{a+b-x}(f), \bigvee_{a+b-x}^{b}(f)\right\}}
\end{array}\right.
\end{aligned}
$$

where $\bigvee_{c}^{d}(f)$ denotes the total variation of $f$ on $[c, d]$. The constant $\frac{1}{4}$ is best possible in the first branch of the second inequality in (2.2).

Proof. We use the fact that for a continuous function $p:[c, d] \rightarrow \mathbb{R}$ and a function $v:[a, b] \rightarrow \mathbb{R}$ of bounded variation, one has the inequality

$$
\begin{equation*}
\left|\int_{c}^{d} p(t) d v(t)\right| \leq \sup _{t \in[c, d]}|p(t)| \bigvee_{c}^{d}(v) \tag{2.3}
\end{equation*}
$$

Taking the modulus in (2.1) we have
$\left|\frac{1}{2}[f(x)+f(a+b-x)]-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right|$
$\leq \frac{1}{b-a}\left[\left|\int_{a}^{x}(t-a) d f(t)\right|+\left|\int_{x}^{a+b-x}\left(t-\frac{a+b}{2}\right) d f(t)\right|\right.$
$\left.+\left|\int_{a+b-x}^{b}(t-b) d f(t)\right|\right]$
$\leq \frac{1}{b-a}\left[(x-a) \bigvee_{a}^{x}(f)+\left(\frac{a+b}{2}-x\right) \bigvee_{x}^{a+b-x}(f)+(x-a) \bigvee_{a+b-x}^{b}(f)\right]=: M(x)$
and the first inequality in (2.2) is obtained.
Now, observe that

$$
\begin{aligned}
\mathrm{M}(x) & \leq \frac{1}{b-a} \max \left\{x-a, \frac{a+b}{2}-x\right\}\left[\bigvee_{a}^{x}(f)+\bigvee_{x}^{a+b-x}(f)+\bigvee_{a+b-x}^{b}(f)\right] \\
& =\frac{1}{b-a}\left[\frac{1}{4}(b-a)+\left|x-\frac{3 a+b}{4}\right|\right] \bigvee_{a}^{b}(f)
\end{aligned}
$$

and the first branch in the second inequality in (2.2) is proved.
Using Hölder's discrete inequality we have (for $\alpha>1, \frac{1}{\alpha}+\frac{1}{\beta}=1$ ) that

$$
\begin{aligned}
\mathrm{M}(x) \leq & \frac{1}{b-a}\left[(x-a)^{\alpha}+\left(\frac{a+b}{2}-x\right)^{\alpha}+(x-a)^{\alpha}\right]^{\frac{1}{\alpha}} \\
& \times\left[\left[\bigvee_{a}^{x}(f)\right]^{\beta}+\left[\bigvee_{x}^{a+b-x}(f)\right]^{\beta}+\left[\bigvee_{a+b-x}^{b}(f)\right]^{\beta}\right]^{\frac{1}{\beta}}
\end{aligned}
$$

giving the second branch in the second inequality.
Finally, we have

$$
\begin{aligned}
& \mathrm{M}(x) \leq \frac{1}{b-a} \max \left\{\bigvee_{a}^{x}(f), \bigvee_{x}^{a+b-x}(f), \bigvee_{a+b-x}^{b}(f)\right\} \\
& \times\left[(x-a)+\left(\frac{a+b}{2}-x\right)+(x-a)\right],
\end{aligned}
$$

which is equivalent with the last inequality in (2.2).
The sharpness of the constant $\frac{1}{4}$ in the first branch of the second inequality in 2.2 will be proved in a particular case later.

Corollary 2.4. With the assumptions in Theorem 2.3, one has the trapezoid inequality

$$
\begin{equation*}
\left|\frac{f(a)+f(b)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{2} \bigvee_{a}^{b}(f) \tag{2.4}
\end{equation*}
$$

The constant $\frac{1}{2}$ is best possible in 2.4.
Proof . Follows from the first inequality in (2.2) on choosing $x=a$. For the sharpness of the constant, assume that (2.4) holds with a constant $A>0$, i.e.,

$$
\begin{equation*}
\left|\frac{f(a)+f(b)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq A \bigvee_{a}^{b}(f) \tag{2.5}
\end{equation*}
$$

If we choose $f:[a, b] \rightarrow \mathbb{R}$ with

$$
f(x)=\left\{\begin{array}{lll}
1 & \text { if } & x=a \\
0 & \text { if } & x \in(a, b), \\
1 & \text { if } & x=b
\end{array}\right.
$$

then $f$ is of bounded variation on $[a, b]$ and

$$
\frac{f(a)+f(b)}{2}=1, \quad \int_{a}^{b} f(t) d t=0, \quad \text { and } \bigvee_{a}^{b}(f)=2
$$

giving in 2.5 $1 \leq 2 A$, thus $A \geq \frac{1}{2}$ and the corollary is proved.
Remark 2.5. The inequality (2.4) was first proved in a different manner in [8].
Corollary 2.6. With the assumptions in Theorem 2.3, one has the midpoint inequality

$$
\begin{equation*}
\left|f\left(\frac{a+b}{2}\right)-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{2} \bigvee_{a}^{b}(f) \tag{2.6}
\end{equation*}
$$

The constant $\frac{1}{2}$ is best possible in (2.6).
Proof . Follows from the first inequality in 2.2 on choosing $x=\frac{a+b}{2}$. For the sharpness of the constant, assume that (2.6) holds with a constant $B>0$, i.e.,

$$
\begin{equation*}
\left|f\left(\frac{a+b}{2}\right)-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq B \bigvee_{a}^{b}(f) \tag{2.7}
\end{equation*}
$$

If we choose $f:[a, b] \rightarrow \mathbb{R}$ with

$$
f(x)=\left\{\begin{array}{lll}
0 & \text { if } & x \in\left[a, \frac{a+b}{2}\right), \\
1 & \text { if } & x=\frac{a+b}{2}, \\
0 & \text { if } & x \in\left(\frac{a+b}{2}, b\right]
\end{array}\right.
$$

then $f$ is of bounded variation on $[a, b]$, and $\mathrm{f}\left(\frac{a+b}{2}\right)=1, \int_{a}^{b} f(t) d t=0$, and $\bigvee_{a}^{b}(f)=2$, giving in (2.7), $1 \leq 2 B$, thus $B \geq \frac{1}{2}$.

Remark 2.7. The inequality (2.6) was firstly proved in a different manner in [9].
The best inequality we may get from Theorem 2.3 on using the bound provided by the first branch in the second inequality in $(2.2)$ is incorporated in the following corollary.

Corollary 2.8. With the assumptions in Theorem 2.3, one has the inequality:

$$
\begin{equation*}
\left|\frac{f\left(\frac{3 a+b}{4}\right)+f\left(\frac{a+3 b}{4}\right)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq \frac{1}{4} \bigvee_{a}^{b}(f) \tag{2.8}
\end{equation*}
$$

The constant $\frac{1}{4}$ is best possible.
Proof . Follows by Theorem 2.3 on choosing $x=\frac{3 a+b}{4}$.
To prove the sharpness of the constant $\frac{1}{4}$, assume that 2.8 holds with a constant $C>0$, i.e.,

$$
\begin{equation*}
\left|\frac{f\left(\frac{3 a+b}{4}\right)+f\left(\frac{a+3 b}{4}\right)}{2}-\frac{1}{b-a} \int_{a}^{b} f(t) d t\right| \leq C \bigvee_{a}^{b}(f) \tag{2.9}
\end{equation*}
$$

Consider the function $f:[a, b] \rightarrow \mathbb{R}$, given by

$$
f(x)=\left\{\begin{array}{lll}
1 & \text { if } & x \in\left\{\frac{3 a+b}{4}, \frac{a+3 b}{4}\right\}, \\
0 & \text { if } & x \in[a, b] \backslash\left\{\frac{3 a+b}{4}, \frac{a+3 b}{4}\right\} .
\end{array}\right.
$$

Then $f$ is of bounded variation on $[a, b]$,

$$
\frac{f\left(\frac{3 a+b}{4}\right)+f\left(\frac{a+3 b}{4}\right)}{2}=1, \quad \int_{a}^{b} f(t) d t=0
$$

and

$$
\bigvee_{a}^{b}(f)=4
$$

giving in (2.9) $4 C \geq 1$, thus $C \geq \frac{1}{4}$.
This example can be used to prove the sharpness of the constant $\frac{1}{4}$ in (2.2) as well.

## 3. Applications for P.D.F.'s

Let $X$ be a random variable taking values in the finite interval $[a, b]$, with the probability density function $f:[a, b] \rightarrow[0, \infty)$ and with the cumulative distribution function $F(x)=\operatorname{Pr}(X \leq x)=$ $\int_{a}^{x} f(t) d t$.

We may state the following theorem.
Theorem 3.1. With the above assumptions, we have the inequality

$$
\begin{align*}
& \left|\frac{1}{2}[F(x)+F(a+b-x)]-\frac{b-E(X)}{b-a}\right|  \tag{3.1}\\
& \leq \frac{1}{b-a}\left\{\left(2 x-\frac{3 a+b}{4}\right)[F(x)-F(a+b-x)]+(x-a)\right\} \\
& \leq \frac{1}{4}+\left|x-\frac{3 a+b}{4} b-a\right|,
\end{align*}
$$

foranyx $\in\left[a, \frac{a+b}{2}\right]$, where $E(X)$ denotes the expectation of $X$, namely $E(X)=\int_{a}^{b} t d F(t)$.

Proof. If we apply Theorem 2.3 for $F$, which is monotonic nondecreasing, we get

$$
\begin{aligned}
& \left|\frac{1}{2}[F(x)+F(a+b-x)]-\frac{1}{b-a} \int_{a}^{b} F(t) d t\right| \\
& \leq \frac{1}{b-a}\left[(x-a) F(x)+\left(\frac{a+b}{2}-x\right)(F(a+b-x)-F(x))\right. \\
& +(x-a)(1-F(a+b-x))] \\
& \leq \frac{1}{4}+\left|x-\frac{3 a+b}{4} b-a\right| .
\end{aligned}
$$

Since
$E(X)=\int_{a}^{b} t d F(t)=b-\int_{a}^{b} F(t) d t$,
thenby (3.2) weget (3.1) andthetheoremisproved.
In particular, we have:
Corollary 3.2. With the above assumptions, we have:

$$
\left|\frac{1}{2}\left[F\left(\frac{3 a+b}{4}\right)+F\left(\frac{a+3 b}{4}\right)\right]-\frac{b-E(X)}{b-a}\right| \leq \frac{1}{4} .
$$

## 4. A Composite Quadrature Formula

Let $I_{n}: a=x_{0}<x_{1}<\cdots<x_{n-1}<x_{n}=b$ be a division of the interval $[a, b]$ and $h_{i}:=x_{i+1}-x_{i}$ $(i=0, \ldots, n-1)$ and $\nu\left(I_{n}\right):=\max \left\{h_{i} \mid i=0, \ldots, n-1\right\}$.

Consider the composite quadrature rule

$$
\begin{equation*}
Q_{n}\left(I_{n}, f\right)=\frac{1}{2} \sum_{i=0}^{n-1}\left[f\left(\frac{3 x_{i}+x_{i+1}}{4}\right)+f\left(\frac{x_{i}+3 x_{i+1}}{4}\right)\right] h_{i} . \tag{4.1}
\end{equation*}
$$

The following result holds.
Theorem 4.1. Let $f:[a, b] \rightarrow \mathbb{R}$ be a function of bounded variation on $[a, b]$. Then we have

$$
\begin{equation*}
\int_{a}^{b} f(t) d t=Q_{n}\left(I_{n}, f\right)+R_{n}\left(I_{n}, f\right) \tag{4.2}
\end{equation*}
$$

where $Q_{n}\left(I_{n}, f\right)$ is defined in formula (4.1), and the remainder $R_{n}\left(I_{n}, f\right)$ satisfies the estimate

$$
\begin{equation*}
\left|R_{n}\left(I_{n}, f\right)\right| \leq \frac{1}{4} \nu\left(I_{n}\right) \bigvee_{a}^{b}(f) . \tag{4.3}
\end{equation*}
$$

The constant $\frac{1}{4}$ is best possible.
Proof . Applying Corollary 2.8 on the interval $\left[x_{i}, x_{i+1}\right]$ we may state that

$$
\begin{equation*}
\left|\int_{x_{i}}^{x_{i+1}} f(t) d t-\frac{1}{2}\left[f\left(\frac{3 x_{i}+x_{i+1}}{4}\right)+f\left(\frac{x_{i}+3 x_{i+1}}{4}\right)\right] h_{i}\right| \leq \frac{1}{4} h_{i} \bigvee_{x_{i}}^{x_{i+1}}(f), \tag{4.4}
\end{equation*}
$$

for any $i \in\{0, \ldots, n-1\}$.
Summing the inequality (4.4) over $i$ from 0 to $n-1$, and using the generalized triangle inequality we get

$$
\left|R_{n}\left(I_{n}, f\right)\right| \leq \frac{1}{4} \sum_{i=0}^{n-1} h_{i} \bigvee_{x_{i}}^{x_{i+1}}(f) \leq \frac{1}{4} \nu\left(I_{n}\right) \sum_{i=0}^{n-1} \bigvee_{x_{i}}^{x_{i+1}}(f)=\frac{1}{4} \nu\left(I_{n}\right) \bigvee_{a}^{b}(f),
$$

and the proof is completed.
For the particular case when the division $I_{n}$ is equidistant, i.e.,

$$
I_{n}: x_{i}=a+i \cdot \frac{b-a}{n}, \quad i=0, \ldots, n,
$$

we may consider the quadrature rule:

$$
Q_{n}(f):=\frac{b-a}{2 n} \sum_{i=0}^{n-1}\left\{f\left[a+\left(\frac{4 i+1}{4 n}\right)(b-a)\right]+f\left[a+\left(\frac{4 i+3}{4 n}\right)(b-a)\right]\right\} .
$$

The following corollary will be more useful in practice.
Corollary 4.2. With the assumption of Theorem 4.1, we have

$$
\begin{equation*}
\int_{a}^{b} f(t) d t=Q_{n}(f)+R_{n}(f), \tag{4.5}
\end{equation*}
$$

where $Q_{n}(f)$ is defined by (4) and the remainder $R_{n}(f)$ satisfies the estimate

$$
\begin{equation*}
\left|R_{n}(f)\right| \leq \frac{1}{4} \cdot \frac{b-a}{n} \bigvee_{a}^{b}(f) \tag{4.6}
\end{equation*}
$$

The constant $\frac{1}{4}$ is sharp.
Remark 4.3. If one is interested in finding the minimal number of points for the equidistant partition $I_{n}$ so that the theoretical error in (4.6) is smaller that $\varepsilon>0$, then this number $n_{\varepsilon}$ is given by

$$
\begin{equation*}
n_{\varepsilon}:=\left[\frac{1}{4} \cdot \frac{b-a}{\varepsilon} \bigvee_{a}^{b}(f)\right]+1 \tag{4.7}
\end{equation*}
$$

where [a] denotes the integer part of the positive number a.
