Palladium(0)-catalyzed synthesis of 3,4-dihydro-2-methylene-2H-1-benzopyran-4-ols via annulation between salicylaldehyde and propargyl carbonate using a formate reductant is reported herein. The annulation proceeds via common addition of the hydroxyl group in salicylaldehyde to the central carbon of η^3 -allenyl-/propargylpalladium, wherein the latter is generated through the oxidative addition of propargyl carbonate to the catalyst and subsequent intramolecular umpolung allylation of the aldehyde.

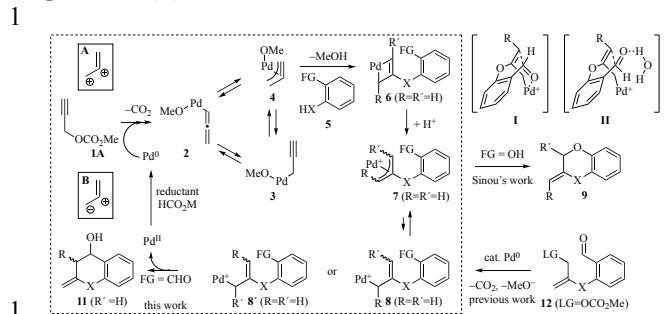

Key words: Palladium catalyst | Salicylaldehyde | Propargyl carbonate | [4+2] Annulation | Umpolung Allylation

Transition metal-catalyzed annulation forming two or multiple bonds in a single step is one of the most useful methods to construct heterocycles and carbocycles, which are important in biology and material science fields.¹ Recently, a palladium-catalyzed annulation reaction using propargyl carbonate **1A** as dicationic synthon **A** with various bifunctional pronucleophiles has been receiving increasing attention (Scheme 1).²⁻¹⁴

Propargyl carbonate **1A** undergoes oxidative addition to a palladium(0) complex and subsequent decarboxylation to afford η^1 -allenylpalladium(II) **2**, which equilibrates with η^1 -propargylpalladium(II) **3** and η^3 -allenyl-/propargylpalladium(II) **4** (Scheme 1).¹⁵⁻¹⁹ These (methoxo)palladium complexes **2-4** can deprotonate pronucleophiles, such as phenol **5** ($X = O$), generating an ion pair containing an anionic nucleophile and cationic palladium together with methanol. Then, a nucleophilic attack of the counter anion to the central carbon of η^3 -allenyl/propargyl ligand in **4** occurs to form palladacyclobutene **6**, which is converted to η^3 -allylpalladium(II) **7**, via protonation and subsequent isomerization of thermodynamically unfavorable η^1 -allylpalladium(II) **8** or **8'**. The η^3 -complex **7** can further react with another nucleophile. Therefore, a tethered bis(pronucleophile), such as catechol **5** ($FG = OH$, $X = O$), can undergo annulation with **1A** to afford 2,3-dihydro-1,4-benzodioxin **9**.⁵ In contrast, the annulation of **1A** with substrate **5** bearing both pronucleophile and electrophilic moieties ($FG = CHO$), such as salicylaldehyde, can be developed because the intermediate **8** is rarely detected but it is sufficiently nucleophilic to attack the intramolecular carbonyl group.²⁰ However, to the best of our knowledge, the latter annulation process using **1A** as Zwitter ionic

synthon **B** yielding functionalized 2H-1-benzopyran-4-ol **11** ($X = O$) has never been developed.^{21,22}

Recently, we reported palladium(0)-catalyzed umpolung cyclizations of allylic carbonate-aldehydes in the presence of formate reductant.^{23,24} The type II cyclization of **12** is supposed to proceed through η^1 -allylpalladium(II) intermediate **8** (Scheme 1). The formate can selectively reduce the alkoxopalladium(II) species (generated at the end of the catalytic cycle) over η^3 -allylpalladium(II) **7**. Unfortunately, the preparation of substrate **12** requires multiple laborious steps. Subsequently, we anticipated that the palladium-catalyzed *in situ* preparation of **8** from propargyl carbonate **1A** and salicylaldehyde **5** ($FG = CHO$, $X = O$) followed by umpolung allylation, which affords **11**, could solve the problem. To achieve the annulation reaction, it is essential to seek reaction conditions that do not reduce palladium(II) intermediates **2-4**²⁵ as well as **7** and **8**.²⁶

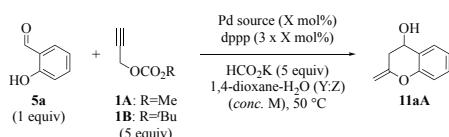

Scheme 1. Palladium-catalyzed annulation of **1** and **5** and type II umpolung cyclization of **12** leading to **11**.

First, reductants (HCO_2H , HCO_2H-Bu_3N , HCO_2NH_4 , HCO_2Na , HCO_2K , and HCO_2Cs , 1.5 equiv) and phosphine ligands (dppe [*1,2*-bis(diphenylphosphino)ethane], dppp [*1,3*-bis(diphenylphosphino)propane], dppb [*1,4*-bis(diphenylphosphino)butane], dppf [*1,1'*-bis(diphenylphosphino)ferrocene], DPEphos [*2,2*'-bis(diphenylphosphino)diphenyl ether, 40 mol%]) were examined for the coupling reaction of salicylaldehyde (**5a**) with 2 equiv of methyl propargyl carbonate (**1A**) under catalysis of $Pd_2(dbu)_3 \cdot CHCl_3$ in 1,4-dioxane at 50 °C (See Supporting Information, Tables S1 and S2). A combination of potassium formate²⁷ and dppp as the reductant and ligand, respectively provided the best result, affording 2-methylenechroman-4-ol (**11aA**) in 38% yield, although it was still necessary to improve the yield. Interestingly, the use of dppf or DPEphos^{10a-c} afforded 2,2'-(prop-2-ene-1,2-diylibis(oxy))-dibenzaldehyde (**13aA**), rather than **11aA**, in high yield, whereas dppb afforded an equal amount of **11aA**.

1 and **13aA** in low yields (See Supporting Information, Table 2, Entries 2–4).

Considering the inevitable reduction of propargyl carbonate **1A**, 5 equiv of **1A** and potassium formate was utilized to screen a solvent for the annulation of salicylaldehyde (**5a**) under 10 mol% $\text{Pd}_2\text{dba}_3\cdot\text{CHCl}_3$ -dppp catalysis while heating at 50 °C (Table 1). Remarkably, the yield of **11aA** increased to 76% when 20 vol% of water was added to 1,4-dioxane (Entries 1–4).²⁸ The concentration of **5a** also affected the yield of **11aA**, with 0.10 M concentration offering the best result (Entry 5). Use of 2 equiv of **1A** and potassium formate instead of 5 equiv lowered the yield of **11aA** (Entry 6). Notably, the annulation proceeded even in the absence of formate; however, it accompanied the formation of diyne derived from oxidative dimerization of **1A** (Entry 7). Reducing the catalyst loading to 5 mol% lowered the yield of **11aA** (Entry 8). Other palladium sources such as $\text{Pd}(\text{OAc})_2$ and (allyl)CpPd instead of $\text{Pd}_2\text{dba}_3\cdot\text{CHCl}_3$ required longer reaction time for the complete consumption of **5a** (Entries 9 and 10). Fortunately, the reaction at 65 °C with *tert*-butyl carbonate **1B** instead of **1A** recovered the yield of **11aA** to 78% (Entry 12). The consumption of **1B** via its oxidative dimerization is suppressed by its steric bulkiness, as observed in Entry 7.

12 ^e	1B	$\text{Pd}_2\text{dba}_3\cdot\text{CHCl}_3$ (5 mol%)	4:1	0.10	9	78 (74) ^f

29 ^aNMR yield of **11aA**. ^bReaction with 2 equiv of **1A** and HCO_2K . ^cReaction without HCO_2K . ^d15 mol% of dppp was used. ^eReaction at 65 °C. ^fIsolated yield of **11aA** is shown in parenthesis.

33 With the optimized reaction conditions (Table 1, Entry 12), the reactions of commercially available 34 salicylaldehydes **5b–l** having various substituents at the 3-, 35 4-, or 5-positions were tested (Table 2, Entries 1–11). 36 Results showed that electron-donating methyl, methoxy, and 37 diethylamino groups were compatible, and the position of 38 the methoxy group affected the product yields to some 39 extent (Entries 1–5). Salicylaldehydes **5g–j** with an 40 electron-withdrawing halogen or nitro group at the 3- 41 position also participated in the annulation to afford **11(g–j)A** in moderate yield (Entries 6–9). Notably, the bromo 42 substituent in **5i** remained intact without suffering reduction 43 under the palladium catalysis (Entry 8). Both 2-hydroxy-1- 44 naphthaldehyde **5k** and its isomer **5l** equally underwent 45 annulation to afford tricyclic products **11kA** and **11lA**, 46 respectively in good yields (Entries 10 and 11). The 47 annulation of *o*-nitrobenzenesulfonyl-protected 2- 48 aminobenzaldehyde **5m**, instead of salicylaldehyde, also 49 occurred, affording 2-methylene-1,2,3,4-tetrahydroquinoline 50 **11mA** in 57% yield (Table 2, Entry 12).

2

3 Finally, the scope of propargyl carbonates was briefly
4 investigated (Table 3). Both isomeric methyl-substituted
5 carbonates **1C** and **1C'** were converted to *cis*- and *trans*-
6 **11aC** in a ca. 4:1 ratio (Entries 1 and 2), which implies that
7 these reactions proceeded through a common η^3 -
8 allylpalladium(II). Similarly, phenyl-substituted **1D** and **1D'**
9 yielded *cis*- and *trans*-**11aD** with poor diastereoselectivity
10 (Entries 3 and 4). Notably, the annulations with internal
11 alkynes (**1C'** and **1D'**) were less efficient than those with
12 terminal alkynes (**1C** and **1D**) because of the formation of
13 byproducts derived from the reduction of η^3 -
14 allylpalladium(II) intermediates (Entries 1, 3 vs. 2, 4).
15 Although each pair of the isomers should behave similarly,
16 the differences in the product yields are ascribed to the
17 initially formed η^1 -allylpalladium(II) **8** and **8'** ($R = Me$ or Ph ,
18 $R' = H$) (Scheme 1).²⁹ Interestingly, the use of non-aqueous
19 solvent in the annulation between **5a** and **1C** resulted in the
20 reversal of diastereoselectivity (Entries 1 vs. 5). The
21 diastereoselectivity was determined via the Zimmerman-
22 Traxler transition state **I** in non-aqueous solvents or the
23 antiperiplanar transition state **II** in aqueous solvents; both
24 states are derived from thermodynamically favored *syn*- η^3 -
25 allylpalladium(II) intermediates (Scheme 1).

26 In conclusion, we have developed a palladium(0)-
27 catalyzed annulation of salicylaldehydes with propargyl
28 carbonate that affords 3,4-dihydro-2-methylene-2H-1-
29 benzopyran-4-ols in good to moderate yields. Various
30 substituents, including bromide on the salicylaldehydes,
31 were tolerated under mild reaction conditions. It was
32 demonstrated that the allylpalladium intermediate, generated
33 by the addition of the hydroxy group in the salicylaldehyde
34 to η^3 -allenyl-/propargylpalladium(II), could undergo
35 nucleophilic addition to intramolecular aldehyde using a
36 formate reductant.

37

38 **Table 3.** Scope of propargyl carbonates **1**

Entry	1	Product	Time (h)	Yield (<i>cis:trans</i>) ^a
1		11aC	5	54% (4.2:1) ^b
2		11aC	5	39% (4.4:1) ^c
3		11aD	1.5	58% (1.1:1)
4		11aD	1.5	39% (1.1:1) ^d
5 ^e		11aC	1.5	60% (1:3.3)

40 ^a The *dr* was determined by ¹H-NMR analysis of the diastereomeric mixture. ^b 2-(But-1-en-2-yloxy)benzaldehyde (**14**) was also observed in 4% NMR yield. ^c **14** and (*Z*)-2-(but-2-en-2-yloxy)benzaldehyde (**15**) were also observed in 33% and 7% NMR yields, respectively. ^d 2-(3-phenylprop-1-en-2-yl)oxy)benzaldehyde (**16**) and (*Z*)-2-(1-phenylprop-1-en-2-yl)oxy)benzaldehyde (**17**) were also observed in 33% and 22% NMR yields, respectively. ^e Reaction in 1,4-dioxane.

104 22 Liang and co-workers reported a palladium-catalyzed annulation
105 of 3-(2-formylphenyl)-substituted propargyl carbonate with
106 amine as an external nucleophile to afford 2-naphthalenamine. It
107 is unclear how the carbonyl group undergoes the electrophilic
108 addition prior to the dehydration. Amine-promoted allene-
109 carbonyl cyclization proposed by the authors or enamine attack
110 would be more likely than umpolung allylation with
111 allylpalladium intermediate because it cannot form
112 Zimmerman-Traxler transition state like **10**. F.-R. Gou, P.-F.

127 28 Although the role of water remains unclear, it can be involved in
128 antiperiplanar transition state **II** to avoid a ring strain in
129 Zimmerman-Traxler transition state **I** tethered by the planar
130 benzene.
131 29 The annulation between **5a** and deuterated propargyl carbonate
132 **1B** afforded deuterated **11aA**, in which deuteriums are
133 incorporated at allylic and vinylic positions equally (see
134 135 136 137

1 Supporting Information). This result indicates that initially
2 formed η^1 -allylpalladium(II) should undergo isomerization into
3 η^3 -complex prior to umpolung carbonyl allylation. However, it
4 might be possible that a substituent on the vinyl group in η^1 -
5 allylpalladium **8'** retards the isomerization to some extent due to
6 steric repulsion with a dppp ligand.
7

NOTE

The diagram is acceptable in a colored form. Publication of the colored G.A. is free of charge.

For publication, electronic data of the colored G.A. should be submitted. Preferred data format is EPS, PS, CDX, PPT, and TIFF.

If the data of your G.A. is "bit-mapped image" data (not "vector data"), note that its print-resolution should be 300 dpi.

You are requested to put a brief abstract (50-60words, one paragraph style) with the graphical abstract you provided, so that readers can easily understand what the graphic shows.

Graphical Abstract	
Textual Information	
A brief abstract (required)	Palladium(0)-catalyzed synthesis of 3,4-dihydro-2-methylene-2 <i>H</i> -1-benzopyran-4-ols via the annulation between salicylaldehyde and propargyl carbonate with the aid of formate reductant is reported. The annulation proceeds through a common addition of the hydroxyl group in salicylaldehyde to the central carbon of η^3 -allenyl-/propargylpalladium, which is generated by oxidative addition of propargyl carbonate to the catalyst, and subsequent intramolecular umpolung allylation of the aldehyde.
Title (required)	Palladium(0)-Catalyzed [4+2] Annulation of Salicyldehydes and Propargyl Carbonates Leading to 3,4-Dihydro-2-Methylene-2 <i>H</i> -1-Benzopyran-4-Ols
Authors' Names (required)	Ayumu Kawase, Hirotaka Omura, Hirokazu Tsukamoto, Takayuki Doi
