TABLE OF CONTENTS

INTRODUCTION

This report summarizes the results of measurements of the CO_2 partial pressure (pCO_2) and total CO_2 concentration (TCO_2) in discrete seawater samples collected during the CONFLUENCE-2 Expedition, September 4 through September 13, 1989, in the southwestern Atlantic Ocean. It has been shown (Takahashi and Chipman, 1985; Peng and Takahashi, in press) that the confluence areas of the Brazil and Malvinas (or Falkland) Currents represent one of the most intense oceanic sink areas for atmospheric CO_2. This has been attributed to the juxtaposition of two effects contributing for reduction of pCO_2 in surface ocean water: 1) the cooling of the warm Brazil Current water as it flows southward, and 2) the photosynthetic utilization of CO_2 as the nutrient-rich sub-Antarctic water flows northward. This investigation has been undertaken in collaboration with Drs. Veronique Garcon and Christine Provost of CNES/GRGS in order to elucidate the carbon dioxide chemistry in the confluence zone.

ACKNOWLEDGMENTS

We gratefully acknowledge financial support of the Centre National de la Recherche Scientifique, Paris, FRANCE, for the field work. Support for the post-expedition data analysis has been provided by funds from the EXXON Research Foundation. We are grateful to vital assistance provided by Dr. Alberto Piola, Hydrographic Office, Argentine Navy, and Dr. Sylvia Garzoli, Lamont-Doherty Geological Observatory, for successful completion of this project. The hydrographic data (temperature, salinity, pressure and the concentrations of oxygen and nutrient salts) listed in this report have been provided by Alberto Piola and Veronique Garcon.

ANALYTICAL METHODS FOR CARBON CHEMISTRY

1) Partial Pressure of CO_2 in Seawater and Air Samples:

The net transfer flux of CO_2 (F) between the surface ocean water and the overlying air is determined by:

$$F = E * [(pCO_2)_{air} - (pCO_2)_{sw}] \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where E is the air-sea CO_2 gas transfer rate constant and $(pCO_2)_{air}$ and $(pCO_2)_{sw}$ are respectively the CO_2 partial pressure in air and surface ocean water. The magnitude of E depends mainly on the turbulence of the interface and may be evaluated as a function of wind speed (e.g. Liss and Merlivat, 1986, Peng and Takahashi, in press, Tans et al., 1990). The pCO_2 values in air and seawater are measured in samples according to the method briefly described below.

A parcel of seawater sample (about 4 liters) is first isolated in a equilibration vessel (about 4.5 liters). About 1 liter of carrier gas (i.e. uncontaminated marine air) is recirculated for about 15 minutes in a closed system using a small gas circulation pump through a gas disperser immersed in the seawater sample. The circulating air is chemically equilibrated with the water sample during this period. Because of the large thermal inertia of the water sample, its temperature remains nearly constant within about 0.2 °C. The temperature of water is measured to $\pm$0.1 °C at the end of each equilibration process, and recorded. The equilibrated gas sample is isolated in a gas sampling flask (about 250 ml) equipped with stopcocks at each end, and shipped back to our land-based laboratories for the pCO_2 determination. In this way, the partial pressure of CO_2 exerted by a sample water is transferred to a gas sample, which can be stcred stably and reliably for a long period of time. After the gas samples are returned to our laboratory, they are analyzed for CO_2 using a gas chromatograph.

The gas chromatograph is similar to that described by Weiss (1981). The CO_2 molecules mixed with hydrogen gas are converted quantitatively to methane using a catalytic column of ruthenium, and the methane molecules produced are detected by a flame-ionization detector. The chromatograph itself yields a precision of about $\pm$0.0 6% for CO_2 analyses, and is calibrated using the WMO standard air-CO_2 mixtures analyzed by C. D. Keeling of SIO.

The gas sample isolated from the equilibrator and injected into the chromatograph for CO_2 analysis is saturated with water vapor at the equilibration temperature. Since the chromatograph measures the number of CO_2 molecules in a known volume of the sampling valve at a known

temperature, the measurement yields pCO_2 directly rather than the mole fraction of CO_2 in dry equilibrated carrier gas. All the determinations of pCO_2 have been performed at least in duplicates. The pCO_2 value thus obtained represents those at the equilibration temperature for each sample, and hence needs to be corrected to the in situ water temperature. The in situ pCO_2 values have been obtained using a temperature coefficient of 0.0423 /°C, which has been determined experimentally by Chipman and Takahashi (in preparation). All the pCO_2 values reported in this report represent those at the in situ temperature. Based upon the duplicate samples collected during the expedition, the overall reproducibility of pCO_2 measurements in seawater has been estimated to be $\pm$2 uatm on the average.

Samples of marine air were also collected during the expedition in gas sampling flasks (about 250 ml). These samples were first dried by passing through a column of P_2O_5, and analyzed for CO_2 using the gas chromatograph. The observed values are listed in Table 1. The pCO_2 value in air saturated with water vapor at the sea surface temperature was then computed using the barometric pressure and the temperature and salinity of surface water measured at the sampling location. The following equation was used for this purpose:

$$(pCO_2)_{air} = (VCO_2)_{air} \cdot (Pb - Pw), \quad \ldots\ldots(2)$$

where $(VCO_2)_{air}$ is the mole fraction concentration of CO_2 in dry air, Pb is the barometric pressure and Pw is the equilibrium water vapor pressure at sea surface temperature and salinity. The following empirical expression was used to compute the equilibrium water vapor pressure, Pw:

$$Pw\ (mm\ Hg) = [1 - 5.3684 \times 10^{-4} \cdot (Sal - 0.03)] \cdot EXP\{[0.0039476 - (1/TK)]/1.8752 \times 10^{-4}\} \quad \ldots\ldots(3)$$

where Sal is salinity in o/oo, and TK is the temperature in °K. The sea-air pCO_2 difference values have been computed as defined below, and are listed in the data table:

$$D\ pCO_2\ (uatm) = (pCO_2)_{sw} - (pCO_2)_{air} \quad \ldots\ldots(4)$$

2) Determination of the Total CO_2 Concentration in Seawater:

For the determination of the total CO_2 concentration in seawater, a coulometer is used. Our coulometer system is similar to that described by Johnson et al (1985), and has been modified from a commercial coulometer

Table 1 Concentrations of CO_2 in marine air observed during the CONFLUENCE-2 Expedition in September, 1989. The Vco_2 values represent the mole fraction of CO_2 in dry air.

(Model-5011) manufactured by the Coulometrics Inc. (Golden. CO). It consists of a CO_2 extraction vessel, a CO_2 absorber cell, and a coulometer. A known volume of a seawater sample (about 25 ml containing about 50 micro-moles of CO_2) is forced into the extraction vessel by a CO_2-free nitrogen gas, and is acidified using 1 ml of 10% phosphoric acid. The liberated CO_2 gas is swept by a stream of nitrogen gas into the CO_2 absorber cell, which is filled with an aqueous solution of dimethylsulfoxide, monoethanolamine, and thymolphthalein. The CO_2 is absorbed quantitatively by this solution, in which it reacts with the monoethanolamine to form hydroxyethylcarbamic acid and lower the pH, thus causing a color change in the thymolphthalein indicator from blue to colorless. The photocell in the coulometer detects the color change, and instructs the unit to pass an electric current through the cell, so that the water in the solution dissociates to generate OH^- ions and hydrogen gas. The OH^- ions neutralize the acid until the original pH is restored in the CO_2 absorber solution. The product of current passed and time represents the amount of CO_2 released from the sea water sample. The entire procedure takes about 7 minutes. We calibrated the coulometer system using five independent methods: 1) gravimetrically prepared $CaCO_3$ standards, 2) gravimetrically prepared Na_2CO_3 standards, 3) volumetrically prepared pure (99.999%) CO_2 gas standards, 4) WMO air-CO_2 gas mixture standards, and 5) a calibrated electrical current meter. We have found that the results of these calibrations agree within 0.1%.

The water samples for the total CO_2 determination were collected in 500 ml Pyrex bottles and were spiked immediately after collections with 250 micro-liters of saturated mercuric chloride solutions in order to prevent biological alterations of sample during storage. Many of the samples were analyzed at sea during the expedition, while some of them were stored for shore-based determinations. Those intended for shore-based study were stored in the 500 ml Pyrex bottles washed with chromic acid prior to the expedition in order to remove organic coatings. After the mercuric chloride spike was added, the bottles were sealed using ground glass stoppers, and a small air space was left in each sample in order to allow space for thermal expansion of water. The purpose of the stored samples is to determine their total CO_2 concentrations more precisely under stable land-based laboratory conditions. No systematic difference has been found between the results of ship board measurements and those obtained in our land-based laboratories. Based upon the results obtained for deep water samples collected below 2000 meters, the precision of the total CO_2 values reported here has been estimated to be about ± 2 uM/kg.

GRAPHICAL PRESENTATION OF THE DATA,

CONFLUENCE-2, SEPTEMBER 4-13, 1989

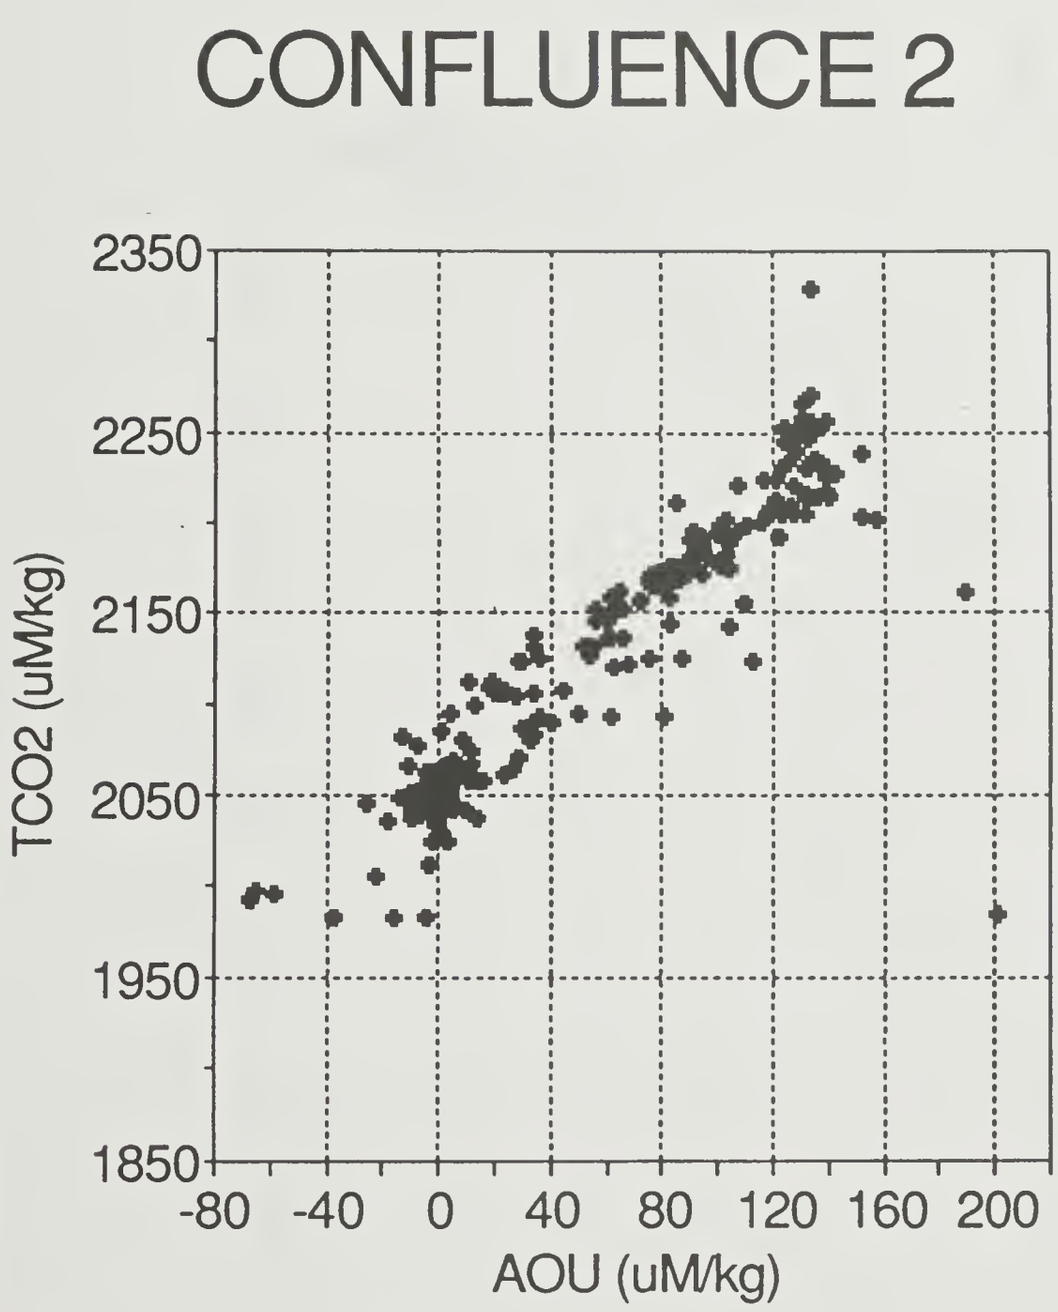

Fig. 11 Vertical distribution of the total CO_2 concentration observed during Confluence-2, September 4-13, 1989. The plus singns indicate the measurements made at sea, and the open square signs indicate those made on land for stored (poisoned) water samples.

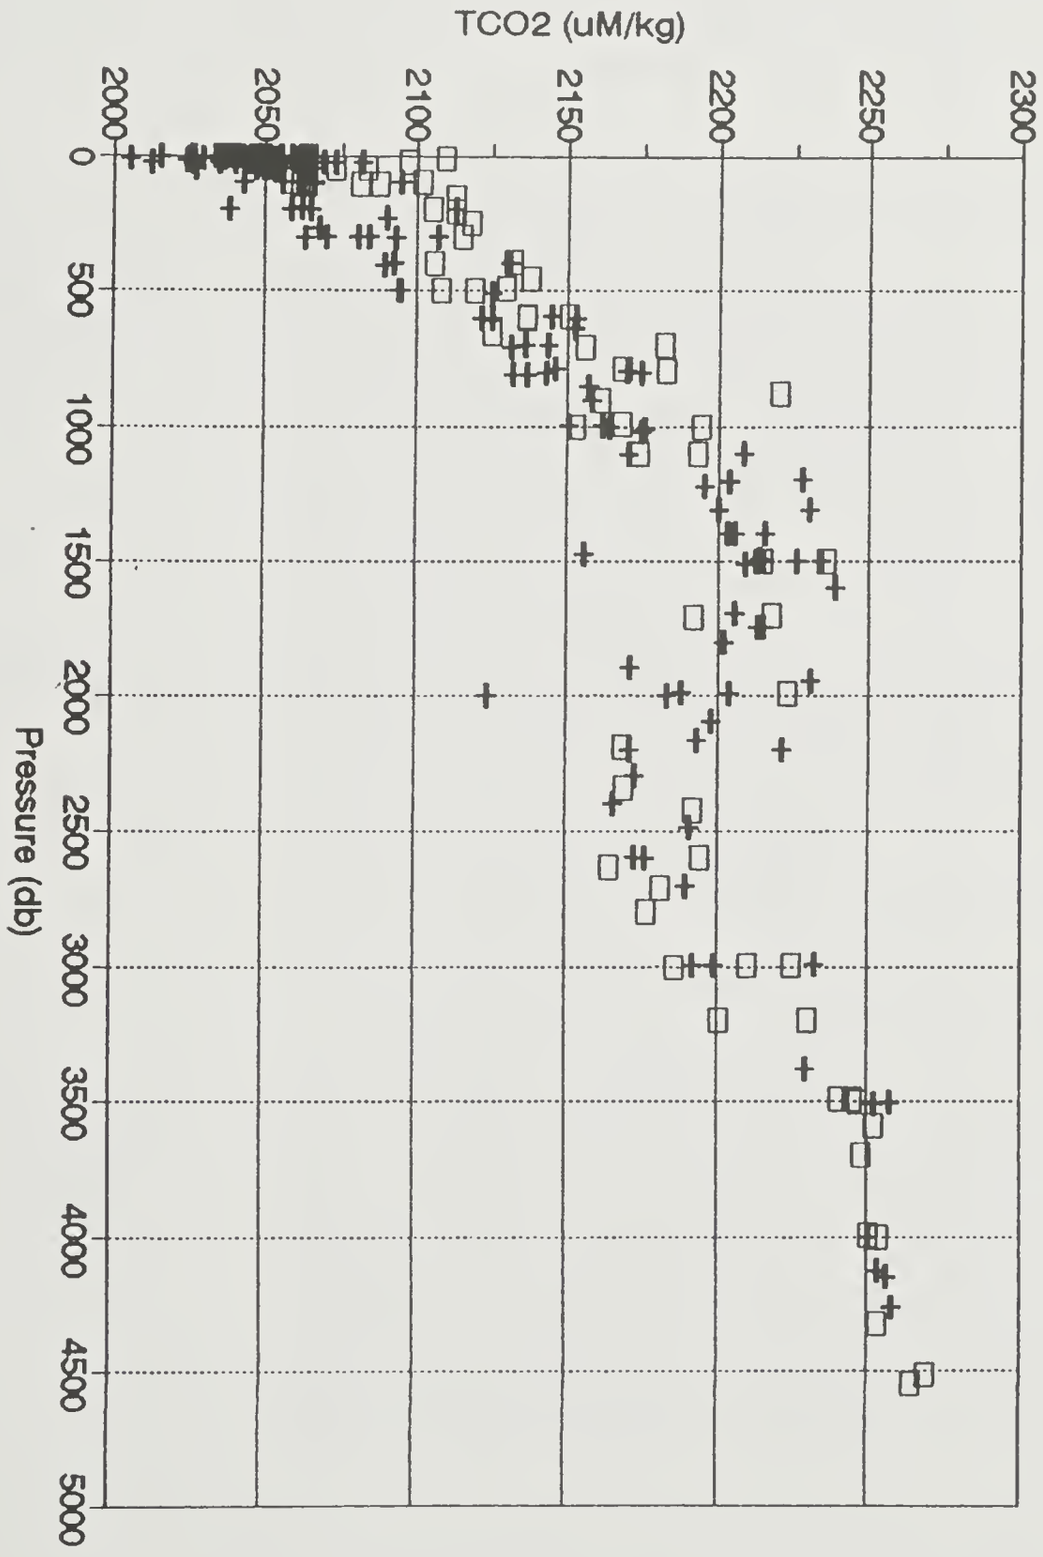

DATA TABLES FOR THE CONFLUENCE-2 EXPEDITION

Definition of the Quantities:

Among the quantities listed, the following quantities have been measured or calculated by the authors of this report; TCO2 (SHIP and LAB), pCO2(sw), pCO2(air), D pCO2, TALK and AOU. All other quantities listed in this report have been measured by the Argentine and French groups and transmitted to us by Drs. Alberto Piola, Veronique Garcon and Christine Provost.

Pres (dbar)	= Pressure in decibars. "0" means sea surface.
T insit (deg C)	= Temperature (°C) at the <u>in situ</u> condition.
Theta (deg C)	= Potential temperature (°C).
Sal (PSU)	= Salinity (o/oo) in the practical salinity unit.
O2 (uM/kg)	= Oxygen concentration dissolved in seawater. The originally reported values in ml STP/liter have been converted to uM/kg using the molar volume of oxygen gas at STP of 22.385 liter/mol and the density of seawater computed for 1 atm. and potential temperature using the International Equation of State for Seawater.
AOU (uM/kg)	= The measured value (above) minus the atmospheric saturation value at the potential temperature. The latter quantity has been computed using the following formula based upon the experimental data of Murray and Riley (1969): $\ln(O_2 \text{ in uM/kg}) = -173.9894 + 255.5907(100/TK) + 146.4813.\ln(TK/100) - 22.2040(TK/100) + Sal[-0.037362 + 0.016504(TK/100) - 0.0020564(TK/100)^2]$, where TK is temperature in °K and Sal is salinity in o/oo.
SiO2 (uM/kg)	= The concentration of total dissolved silica.
PO4 (uM/kg)	= The concentration of dissolved phosphate.
NO3 (uM/kg)	= The concentration of dissolved nitrate in seawater. The concentrations of these three nutrient salts have been determined colorimetrically, and the original per liter values have been converted using the seawater density at the assumed laboratory temperature of 25°C.

TCO2 (uM/kg) --SHIP-- = The total CO_2 concentration of all CO_2 species dissolved in seawater. This has been measured at sea using a coulometer as described in the text.

TCO2 (uM/kg) --LAB-- = The total CO_2 concentration of all CO_2 species dissolved in seawater. This has been measured in our land-based laboratories at Lamont for the stored (poisoned with mercuric chloride) seawater samples.

pCO2(sw) (uatm) = The partial pressure of CO_2 in seawater at the in situ temperature. The method of measurement is described in the text.

pCO2(air) (uatm) = The partial pressure of CO_2 in the marine air at the sea surface. The methods of measurements and computation are described in the text. See Equations (2) and (3) and Table 1.

D pCO2(sw-air) (uatm) = The difference between pCO_2 in surface seawater and that in overlying air. See the text and Equation (4).

TALK (ueq/kg) = The total alkalinity in seawater computed using the measured temperature, salinity, pCO_2 and the concentrations of SiO_2, PO_4, and TCO_2, The method of computation have been described in Peng et al. (1987). A copy of the computer program is attached in Appendix 1.

pH = The seawater pH values, which have been provided to us. The pH scale used and the temperature of measurements are not specified.

```
REM FILE NAME = TALK.BAS

REM THIS IS TO COMPUTE TALK (uEQ/KG) FROM TCO2 AND PCO2 USING
REM MEHRBACH K1 AND K2 FOR CARBONIC ACID, LYMAN KB FOR BORIC ACID,
REM WEISS CO2 SOLUBILTIY, KESTER & PYTKOWICZ KP2 AND KP3 FOR PHOSPHORIC ACID,
REM SILLEN & MARTEL KSI FOR SILICIC ACID, AND MILLERO'S FRMULATION OF KW.
