## Abstract

In situ immobilization of poly[(4-methacryloyloxy-(4'-carboxy)azobenzene)] on silica gel surface has been performed by radical polymerization of monomer. The fact of polymer immobilization is confirmed by IR spectroscopy. TG and DSC-MS analysis showed that the mass of the immobilized polymer was 10.61%. The SEM-microphotograph-synthesized composite analysis showed that the immobilized polymer on the silica gel surface is placed in the form of fibers. It has been found that the synthesized composite exhibits the sorption ability in terms of microquantities of Cu(II), Cd(II), Pb(II), Mn(II) and Fe(III) ions in a neutral aqueous medium. The quantitative sorption of microquantities of Pb(II) and Fe(III) ions has been recorded. It has been found that immobilization of the silica gel surface leads to an increase in its sorption capacitance for Fe(III), Cu(II) and Pb(II) ions by half.

## Introduction

In recent years, the preparation of organic/inorganic hybrid materials composed of organic polymers and silica nanoparticles has been widely investigated. The combination of organic polymer components with nanometer-sized silica fillers in a single material has extraordinary significance for the development of hybrid materials with unique properties (Draxl et al. 2014; Peveler et al. 2014; Yang et al. 2007; Tamaki et al. 1997).

The modification of the surface of porous inorganic materials by nitrogen-containing polymers allows to obtain sorbents for removing toxic metals from the waste water due to their complexation with nitrogen atoms of immobilized polymer (Yanovska et al. 2007; Wan Ngah et al. 2012; Dadashev et al. 2016; Karthik and Meenakshi 2014; Budnyak et al. 2015).

One of the promising ways of creating organo-mineral composite materials with valuable sorption properties is polymerization or in situ immobilization, which consists in the direct formation of an immobilized polymeric layer in

the presence of particles of inorganic matrix (Ryabchenko et al. 2014; Ryabchenko et al. 2016; Yanovska et al. 2017).

The advantages of this method of fixing a polymer on a solid surface in comparison with physical adsorption of pre-synthesized polymers are optimal (both energetic and geometric) location of macromolecules on a solid surface, which strengthens the fixation of a polymer on an inorganic matrix. This arrangement of macromolecules creates additional possibilities for the regeneration of the obtained composite material as a sorbent in multiple applications, and the possibility of self-organization of polymer chains in supra-molecular structures on the surface of an inorganic matrix, the presence of which increases the sorption capacity of the composite (Sapurina and Stejskal 2008; Sowa et al. 2012). Compared to the chemical bonding of pre-synthesized polymers, in situ immobilization is characterized by the absence of the residues of monomolecular compounds on the solid surface of the matrix, which were used as bridging groups between the inorganic matrix and the polymer.

All this leads to expansion of the range of immobilized polymer adsorption ability and improve its adsorption capacity.

This work is devoted to the in situ immobilization of poly[(4-methacryloyloxy-(4'-carboxy)azobenzene)] on the silica gel surface, and adsorption properties of the synthesized composite material on ions Pb(II), Cd(II), Mn(II), Cu(II) and Fe(III).

## Materials and methods

For the study, the silica gel produced by Merck, whose surface parameters are given in Table 1, were used.

### Synthesis of 4-hydroxy-(4'-carboxy)-azobenzene

4-aminobenzoic acid (0.1 mol) was dissolved in a solution of concentrated hydrochloric acid:water (50:50) (100 mL). The mixture was cooled to 0 °C in an ice-water bath, and then sodium nitrite (0.1 mol) dissolved in a small amount of water added dropwise. The reaction mixture was stirred for 2 h, and then phenol (0.1 mol) in NaOH solution (100 mL) was added slowly. The resultant solution was stirred for 4 h at 0–5 °C and for an additional 10 h at room temperature. The precipitate formed was collected by vacuum filtration

and finally dried. The product was purified by recrystallization from ethanol. Yield: 87–92%.

### 4-hydroxy-(4'-carboxy)-azobenzene

<sup>1</sup>H NMR (400 MHz, DMSO, δ, ppm): 7.93–6.89 (3d, s, 7H, Ph-H), 11.4 (s, 1H, COOH), 10.19 (s, 1H, OH).

The synthesis of 4-methacryloyloxy-(4'-carboxy)-azobenzene, is given below: azocompound (2.58 g, 0.01 mol) was dissolved in 25 mL anhydrous THF, and freshly distilled triethylamine (1.53 mL, 0.011 mol) was added to the solution. The reaction mixture was then cooled to 0–5 °C. Methacryloyl chloride (1.07 mL, 0.011 mol) in THF (5 mL) was injected gradually to the above solution via a glass syringe, while the solution temperature was kept below 5 °C. The reaction mixture was stirred overnight at room temperature. The resulting precipitate was filtered off. Purification was followed by recrystallization from methanol. Yield: 63–76%.

### 4-methacryloyloxy-(4'-carboxy)-azobenzene

<sup>1</sup>H NMR (400 MHz, DMSO, δ, ppm): 8.12–6.92 (3d, s, 7H, Ph-H), 11.3 (s, 1H, COOH), 6.28 (s, 1H C=CH<sub>2</sub>, cis), 5.82 (s, 1H C=CH<sub>2</sub>, trans), 2.06 (s, 3H, =C–CH<sub>3</sub>).

The polymerization of 4-methacryloyloxy-(4'-carboxy)-azobenzene in the presence of silica (fraction of particles with a diameter of 0.1–0.2 mm, specific surface 428 m<sup>2</sup>/g, Merck) has been carried out under the argon atmosphere. A solution of 3.5 g 4-methacryloyloxy-(4'-carboxy)-azobenzene and 0.175 g of 2,2'-azobisisobutyronitrile (AIBN) in 80 mL tetrahydrofuran (THF) were poured into a flask containing 15 g of silica gel. When argon blowing was finished after 15 min, the reaction mixture was heated to 68 °C; polymerization continued for 6 h with stirring. The reaction was stopped by cooling the reaction mixture. The resulting suspension was poured into a porcelain cup and left overnight to evaporate the solvent; the synthesized composite was washed three times with isopropyl alcohol, filtered and air-dried for 24 h at room temperature.

### Solutions with different pH values

To create pH 4.0, a standard buffer solution was prepared using a titration substance (ISO 8135: 2009,

**Table 1** Characteristics of the surface of silica gel and synthesized composite

| Silica gel                | 446,9738                          | 463,5319 | 686,9092 | 0,6860                                   | 5,9194                  |
| The synthesized composite | 385,7589                          | 402,1408 | 599,7788 | 0,6069                                   | 6,0365                  |

manufacturer—JSC “Kyiv Plant RIAP”). pH 1.0 was created by adding 0.1 M HCl, pH 2.5—by adding 0.1 M acetic acid. Acid solutions were prepared from fixants. The exact pH of the working solutions was determined using a pH meter “Hanna Combo pH/EC/TDS/Temp tester Model HI98129 low range”.

FTIR spectra of the samples of composite and the silica were recorded using an IR spectrometer with Fourier transformation (Thermo Nicolet Nexus FT-IR, USA). For this purpose, the samples were ground in an agate mortar and pressed with KBr. The FTIR spectra were recorded in the spectral range of 500–4000  $\text{cm}^{-1}$  with 16 scans per spectrum at a resolution of 4  $\text{cm}^{-1}$ .

### Thermal analysis

Thermal analysis was carried out on a STA 449 Jupiter F1, Netzsch (Germany) under the following operational conditions: heating rate of 10  $^{\circ}\text{C min}^{-1}$ , dynamic atmosphere of synthetic air (50  $\text{mL min}^{-1}$ ), temperature range of 30–950  $^{\circ}\text{C}$ , sample mass  $\sim 18$  mg, sensor thermocouple type S TG-DSC. As a reference, empty  $\text{Al}_2\text{O}_3$  crucible was used. The gaseous products emitted during decomposition of material were analyzed by QMS 403C Aeölos (Germany) coupling on-line to STA instrument. The QMS data were gathered in the range from 10 to 160 amu.

### Surface morphology analysis

The surface morphology of composite was observed using a scanning electron microscope (SEM, LEO 1430VP, Carl Zeiss, Germany).

### The investigations of adsorption properties

The investigations of adsorption properties of the obtained composite with respect to Pb(II), Cd(II), Mn(II), Cu(II) and Fe(III) ions were carried out in the static mode with periodic hand stirring. For that, the sample of 0.1 g of synthesized

adsorbent was contacted with 25 mL of solutions at different concentrations of nitrates of the chosen metals. Working nitrate solutions of Pb(II), Cd(II), Mn(II), Cu(II) and Fe(III) are prepared with the sets of “standard sample solutions” of these salts on 1 M  $\text{HNO}_3$  background (produced by A.V. Bogatsky FHI in Odesa) with concentrations of 1 and 10  $\text{mg/mL}$ .

Determination of the equilibrium concentration of the metals was carried out by atomic absorption using a flaming atomic absorption spectrophotometer “Saturn” (Ukraine) in a “air–propane–butane” flame mixture. Maxima wavelengths were: 324.7 nm for Cu(II), 228.8 nm—for Cd(II), 283.3 nm—for Pb(II), 248.3 nm—for Fe(III), aperture being 0.5 cm wide.

The degree of adsorption ( $R$ ) is calculated using the formula:

$$R = (m_{\text{ads}}/m_0) \cdot 100\% = (m_0 - m)/m_0 \cdot 100\% \quad (1)$$

where  $m_0$ —mass of metal in the output solution,  $m_{\text{ads}}$ —mass of adsorbed metal,  $m$ —mass of metal in the equilibrium solution after adsorption, which is calculated as  $m = [\text{M}] \cdot V$ , where  $[\text{M}]$ —equilibrium concentration of metal and  $V$ —volume of equilibrium solution.

## Results and discussion

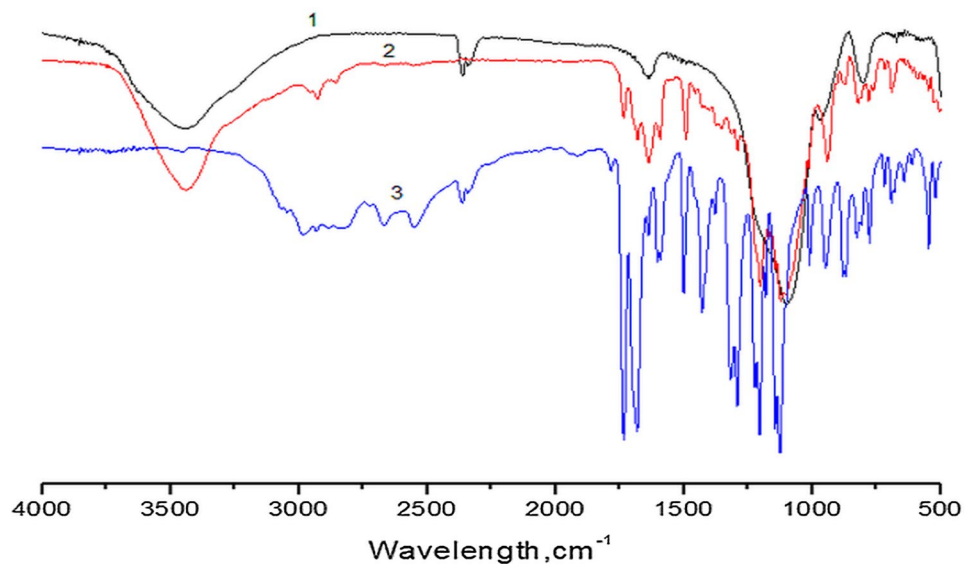

The chemical structure of in situ polymer immobilization 4-methacryloyloxy-(4'-carboxy)-azobenzene on the silica surface could be presented as follows (Fig. 1).

The fact of the process of in situ polymerization and fixing of the polymer on the silica surface were confirmed by comparative analysis of IR spectra of synthesized composite, monomer and original silica gel (Fig. 2). Comparative analysis of the infrared spectra of the synthesized composite, silica gel and monomer (Fig. 2) shows that in contrast to the original silica gel, the absorption bands in the spectrum of the composite are in the range 2870–2845  $\text{cm}^{-1}$ , which correspond to symmetric valence vibrations

**Fig. 1** The scheme of in situ immobilization of poly4-methacryloyloxy-(4'-carboxy)-azobenzene on the silica gel surface

**Fig. 2** The FTIR-spectra of the original silica gel (1) monomer (3) and synthesized composite (2)

of the  $sp^3$  Hybridized Carbon of polymer in the groups CH. These same bands are present in the IR spectrum of a monomer in the region of  $2910\text{--}2850\text{ cm}^{-1}$ . Absorption bands in the region  $1700\text{--}1680\text{ cm}^{-1}$  are present in the spectra of monomer and polymer and correspond to valence vibrations of the CO in aromatic carboxylic acids. A number of bands at  $1600\text{--}1575$  and  $1525\text{--}1475\text{ cm}^{-1}$  can be attributed to the valence vibrations of the C–C of the aromatic system. Weak absorption bands in the region  $1500\text{--}1400\text{ cm}^{-1}$  correspond to the valence vibrations N=N and are observed in the spectra of monomer and polymer. The bands at  $1465\text{--}1440\text{ cm}^{-1}$  can be interpreted as the deformation of the C–H fluctuations in the polymer chain, and the bands at  $1440\text{--}1410\text{ cm}^{-1}$  relate to the valence fluctuations-N=N-azo group (Smith 1982; Tarasovich 2012). Consequently, the results of IR spectroscopy confirm the presence of a polymer on the surface of silica gel.

The influence of polymeric coating on thermal properties of silica were studied by conducting TG and DSC-MS analysis.

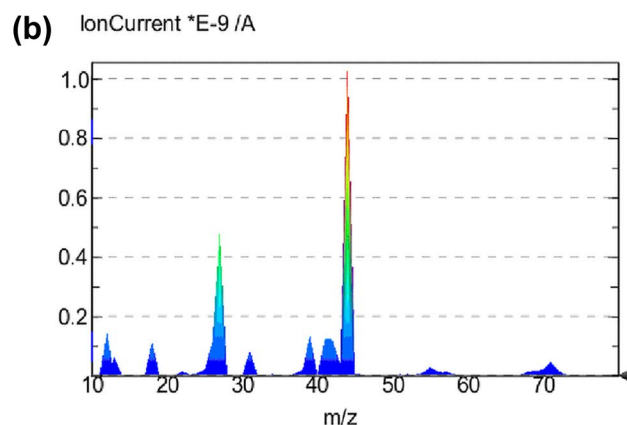

Figures 3 and 4 show the thermograms of the original silica gel and the synthesized composite.

The comparative analysis of the thermograms (Figs. 3 and 4) shows that the main loss of the composite mass due to the thermal decomposition of the immobilized polymer occurs in the range from  $100$  to  $600\text{ }^\circ\text{C}$ . Loss of the composite mass is 16% generally. Taking into account that the mass loss of the original silica gel at this temperature range is 5.39%, it can be argued that the mass fraction of the immobilized polymer in the synthesized composite is 10.61%. Thus, the reaction yield is 50%.

Figure 5 shows a thermogram of a synthesized composite, combined with a mass spectrum in 3D format (Fig. 5a) and a mass spectrum in 2D format (Fig. 5b). Mass spectral studies show that, as a result of thermal degradation of a

**Fig. 3** TG-, DTG-, DSC-curves of the silica

polymer at temperatures above 400 °C, particles with a mass of 18, 28 and 44 Da are most likely formed, which most likely correspond to the formation of water, nitrogen and CO<sub>2</sub>. In the temperature range of 200–400 °C, the formation of a small number of particles with molecular masses 54 and 70, which most likely correspond to fragments of the carbon chain of a polymer.

Table 1 shows the main parameters of the surface of the original silica gel and the synthesized composite, namely the value of the specific area of the surface, calculated by different methods with the data of the sorption–desorption nitrogen isotherms, the mean pore volume and average pore size, found from the pore distribution curves in the investigated samples. As it follows from Table 1, the fixation of this polymer on the surface of the silica gel results in a slight decrease in the surface area, which is logical when placed on a porous surface of silica gel of non-porous polymer. But the average size and volume of pores thus change insignificantly, which suggests that the structure of the surface of the original silica gel at the same time does not change practically.

To clarify the geometrical shapes and geometric location of the CEM-microphotographs of synthesized composite at 50,000× (a), 100,000× (b) magnification-immobilized polymer on the surface of the silica gel, (Fig. 6) was received. As can be seen from Fig. 6, the immobilized polymer on the surface of the silica gel is placed in the form of fibers, and not globules.

The synthesized composite should detect the sorption ability of metal ions due to the complex activity of nitrogen atoms of azo groups and oxygen atoms of carboxylic groups. To confirm these considerations, we investigated the sorption of Cu (II) and Fe(III) ions, which have a high affinity for nitrogen-containing ligands (Skopenko and Savranskij 2004). In addition, the sorption of ions of toxic metals such as Cd (II), Pb(II) and Mn(II), which form complexes with oxygen atoms predominantly, was studied (Skopenko and Savranskij 2004).

The dependence of the adsorption degree of Cu (II), Cd (II), Pb(II), Mn(II) and Fe(III) ions by poly-4-methacryloyloxy-(4'-carboxy) azobenzene, in situ immobilized on silica surface, from the acidity of the medium in the

Experimental conditions: mass of sorbent—0.1 g, volume of solution—25 mL,  $m_M^0$ —100 μg

static mode of adsorption presented in Table 2. The analysis of Table 2 shows that the synthesized composite as a whole exhibits the best sorption properties of the microquantities of the selected ions in the aqueous medium (without the addition of any buffer solutions), where it quantitatively adsorbs the ions of Pb(II) and Fe(III) and removes as much as all other investigated ions of metals possible in comparison with acidic medium.

It should be noted that in the alkaline medium, the polymer is washed away from the surface of silica gel, therefore, the study of sorption properties was carried out in acidic and neutral media only. The acid medium was formed with chloride, acetic acid and phthalate buffer.

At the same time, in the initial solutions of transition metals, chloride, acetate and phthalate complexes could be formed, respectively. In the process of sorption, these complexes interacted with immobilized polymer molecules

**Fig. 7** Dependence of the degree of sorption from contact time in the static mode of nitrates Pb(II)—1, Cu(II)—2, Fe(III)—3

with the formation on solid surfaces of multi-ligand complexes, whose stability constants for a single metal can vary greatly, which affects the degree of its sorption.

This phenomenon is observed in the sorption of Fe(III) ions. Thus, from Table 2, it is seen that the acetate complexes of ferrum (III) are sorted almost completely with the surface of the synthesized composite, while phthalate complexes are sorted one-third only in the analogous conditions of the experiment.

Taking into account the results of the studies presented in Table 2, further investigations of the sorption properties of the synthesized composite were carried out with aqueous solutions of the nitrates of the selected metals only.

Figure 7 shows the dependence of the degree of sorption from static contact time for Pb(II), Cu(II) and Fe(III) ions. As can be seen from this figure, the maximum degree of sorption of ions Pb(II) is achieved within 1 h of contact,

while for Cu(II) and Fe(III) ions the equilibrium is established within a day.

Such a long period of determination of sorption equilibrium is typical of polymer sorbents. Thus, the obtained results confirm indirectly that sorption of metal ions occurs due to chemical interaction with immobilized polymer, and, unfortunately, indicate that this composite cannot be used effectively for sorption of ions of the corresponding metals in a dynamic mode.

To establish and compare the values of the sorption capacitance of the synthesized composite and the original silica gel with respect to Cu(II), Pb(II) and Fe(III) ions, the sorption isotherms of each individual ion from aqueous solutions of nitrates of these metals (without the addition of any buffer solutions) in static mode were constructed and compared with those for the original silica gel. It turned out that the isotherms of sorption of all-investigated metals belong to the 2L-species (Fig. 8), which indicates the uniform distribution of metal ions on the surface of the composite. This type of isotherm is typical for silica matrices, modified by complex-forming substances (Zaitsev 1997).

All obtained isotherms allow to calculate the adsorption capacity of the composite for each of the investigated ions.

The comparison of the sorption capacitance values of the synthesized composite and the original silica gel with respect to Cu(II), Pb(II) and Fe(III) ions calculated from the data processing of adsorption isotherms is given in Table 3.

Comparing the results of studies on the sorption capacity of the formed composite and the original silica gel according to the data of this table, it can be argued that the sorption capacity of the composite for all these ions is twice as high as for the original silica gel.

However, comparing the values of the sorption capacity with the results of thermogravimetric and SEM analysis, it can be noted that, notwithstanding the linear position of the

polymer on the surface of the silica gel, not all of its complexing centers were active in the interaction with the ions of the investigated metals, even under the optimal sorption conditions. The reason for this phenomenon is still unclear to us. Accordingly, the sorption capacity of the synthesized material in relation to the investigated ions is not sufficient for its practical use as a sorbent of these ions.

## Conclusions

A new organo-mineral composite material has been synthesized by in situ immobilization of poly[(4-methacryloyloxy-(4'-carboxy)azobenzene)] on the silica gel surface by polymerization of the 4-methacryloyloxy-(4'-carboxy)azobenzene in the presence of 2,2'-azobisisobutyronitrile as the initiator of radical polymerization. The fact of heterophase polymerization has been confirmed by IR spectroscopy. As a result of thermogravimetric analysis and DSC-MS analysis, it has been found that the composition of synthesized composite includes 1061 wt% of polymer. The analysis of SEM-microphotographs of synthesized composite showed that immobilized polymer on the surface of silica gel is placed in the form of fibers, not globules. As a result of studies on the sorption ability of the synthesized composite for Cu(II), Cd(II), Pb(II), Mn(II) and Fe(III) ions, it was recorded that the synthesized composite as a whole exhibits the best sorption properties relative to the microcavities of the selected ions in the neutral aqueous medium (without the addition of any buffer solutions), where it quantitatively adsorbs the number of ions of Pb(II) and Fe(III) and maximally removes all other investigated metal ions compared to the acidic medium. It was found that the maximum degree of sorption of ions Pb(II) is achieved within 1 h of contact, and for the Cu(II) and Fe(III) ions the equilibrium is established within a day. According to the results of data processing, sorption isotherms have shown that the immobilization of the surface of silica gel leads to an increase in its sorption capacity

relative to Fe(III), Cu(II) and Pb(II) ions by half. However, the sorption capacity of the synthesized material in relation to the investigated ions is not sufficient for its practical use as a sorbent of these ions.
