ABSTRACT

Prevalence and intensity of black-spot disease in a fish community from a subtropical stream (Santa Lucía river basin, Uruguay)

The objective of the present study was to identify fish species susceptible to black spot disease, the temporal variation in intensity prevalence and abundance of black spot, and its correlation with environmental and host parameters. In order to do so, several sampling campaigns were conducted bimonthly during one year, along the main course of an agricultural watershed. A total of twenty-seven fish species were collected, out of which only two, *Astyanax aff. fasciatus* ("mojarra") and *Oligosarcus jenynsii* ("dientudo") presented black spot disease. In *A. aff. fasciatus*, 63 % of black spot prevalence was registered and did not show significant seasonal changes during the sampling period, nor did the abundance and intensity. Regarding possible relations between the disease and environmental and host parameters, a higher intensity of black spot infection was observed in the ventral region of the fish and allometric coefficient ($W_T - L_S$, relationship) values did not differ significantly between parasitized and non-parasitized fish groups.

Key words: Black-spot, metacercariae digeneans, *Astyanax aff. fasciatus*, subtropical stream, Santa Lucía river basin.

RESUMEN

Prevalencia e intensidad de la enfermedad del punto negro en la comunidad de peces en un arroyo subtropical (cuenca del río Santa Lucía, Uruguay)

El objetivo del presente estudio fue identificar las especies susceptibles a la enfermedad del punto negro, la variación temporal de su intensidad, prevalencia y abundancia; así como su relación con parámetros ambientales y del hospedador. Para ello, se realizaron muestreos bimensualmente durante un año, en el curso principal de una cuenca agrícola suburbana. Fueron colectadas un total de veintisiete especies, de las cuales en solo dos, *Astyanax aff. fasciatus* ("mojarra") y *Oligosarcus jenynsii* ("dientudo"), se observó la enfermedad del punto negro. En *A. aff. fasciatus* se registró una prevalencia de puntos negros del 63 % y la misma no presentó diferencias significativas durante el período de muestreo, al igual que su abundancia e intensidad. En cuanto a las posibles relaciones de la enfermedad con parámetros ambientales y del hospedador, se observó una mayor intensidad de la infección en la región ventral de los peces y no se encontraron diferencias significativas en los valores del coeficiente alométrico (relación $W_T - L_S$) entre los peces parasitados y no parasitados.

Palabras clave: Punto negro, metacercarias digenea, *Astyanax aff. fasciatus*, arroyo subtropical, cuenca del río Santa Lucía.

INTRODUCTION

The black-spot disease, caused by encystment of metacercariae of digenic trematodes, produces a response easily recognizable in the fish for the accumulation of melanin around the encysted metacercariae.

The life cycle of these parasites includes two intermediate hosts, the first stage (miriacida) infects snails, and the second intermediaries are fishes. When the cercariae stage comes out from the snails, it massively attacks the fish, entering through the skin, muscles and fins of the fishes remaining there in the metacercariae stage until the infested host is eaten by other fish or waterfowl. In the digestive tract of the final host, the adult flukes reproduce. The eggs are released via excreta and pass to the water where the miraciadia emerges, penetrates the snails and starts a new cycle (Olsen, 1974; de Kinkelin *et al.*, 1985). Freshwater digenean's life cycle is affected by temperature, seasonal changes in prevalence and abundance related to enhance cercarial emergence with an increase in water temperature are reported (Chubb, 1979). To our knowledge, there are no studies in Uruguay about the black-spot disease of freshwater fish; for this reason the prin-

cipal trematodes and its specificity in terms of intermediate hosts (snails and fishes) are unknown.

Several digenic trematode species have been reported as pathogenic for secondary intermediate fish hosts. The infection may be lethal, especially during the first months of the fish life cycle (Lucký, 1970). Both in aquaculture and natural populations, most parasite-fish host systems present negative or neutral impacts of parasites on the host fish survival, growth and condition (Lyayman and Sadkovskaya, 1952; Harrison and Hadley, 1982; Baker and Bulow, 1985; Sindermann, 1987). However, an increased growth of parasitized fish have been informed in several studies, especially related to cestodes parasites (Arnott *et al.* 2000; Museth, 2001; Loot *et al.*, 2002). In digenean larvae infected fishes, increased growth has only been recorded in the Cyprinidae *Phoxinus phoxinus* (Linnaeus, 1758), with this effect disappearing in high infections (Ballabeni, 1994).

These parasites can promote different effects in different fish species with consequences at the population level. In this sense, the aim of the present study was to identify fish species susceptible to black spot disease, its temporal variation regarding intensity, prevalence, abun-

dance, and its correlation with environmental and host parameters.

MATERIAL AND METHODS

The study was carried out in an agricultural watershed located in the lower-basin of Santa Lucía River (Fig. 1), the most important water resource for human consumption in Uruguay (DNH, 1999). The watershed, Cañada del Dragón (34°47'07" S, 56°14'56" W to 34°42'15" S, 56°18'34" W), covers 14.7 km² and approximately 50 % is covered by deciduous fruit-tree plantations. The main course is 13.7 km long, and according to Strahler (1986) criteria, was classified as a third order stream.

Six sampling campaigns were conducted from July 2002 to June 2003, in four sites along the stream to ensure a high number of environments (riffles and pools, vegetated and non-vegetated zones), in order to capture a representative number of the species presented in the Cañada del Dragón stream. Fish were captured using electro fishing (Sachs Elektrofischfanggerate GmbH, Type FEG 1000), and the sampling effort in each site was 15 electric pulses along 100 meters. All fish were classified taxonomically and only the individuals that presented black spot disease were transported to the laboratory. These fish were sacrificed with an overdose of anesthesia (solution of 2-Phenoxy-ethanol, 1 ml L⁻¹), fixed in formalin (10 %), preserved in alcohol (70 %),

and stored at the Vertebrate Collection of Facultad de Ciencias, Universidad de la República (Uruguay) (Institutional code ZVC-P). Samples of fish skin with black spot disease were wholly mounted and the metacercariae, stored in the Helminthological Collection from the above mentioned Facultad de Ciencias.

Water parameters such as pH, dissolved oxygen concentration (mg L⁻¹), conductivity (μS cm⁻¹) and temperature (°C) were measured *in situ*. Water samples were collected and analyzed for alkalinity (mg CaCO₃ L⁻¹), organic matter and total suspended solids (mg L⁻¹) (APHA, 1995). The temporal variation of water physico-chemical parameters was analyzed using the non-parametric Kruskal-Wallis test (Zar, 1999).

In the species that presented black spot disease, prevalence (percentage of fish with black spot disease), mean abundance (mean number of black spots considering all fish examined) and mean intensity (mean number of black spots per fish infected) were calculated following Bush *et al.*, (1997). Temporal variation of prevalence was tested using Proportion tests, whereas changes in abundance and intensity were tested using the non-parametric Kruskal-Wallis test (Zar, 1999).

The relationship between the number of parasites and environment (water physico-chemistry parameters) and host parameters (fish total, standard length, and weight) were evaluated through the non-parametric Spearman correlation test (Sokal and Rohlf, 1979). To determine infection preference, each organism was subdivided in four

Figure 2. *Astyanax aff. fasciatus*, picture showing the four regions of the body employed for the black-spot analysis. Arrow indicates the black spot. *Astyanax aff. fasciatus*, fotografía mostrando las cuatro regiones del cuerpo empleadas para el análisis de los puntos negros. La flecha indica un punto negro.

anatomical regions (Fig. 2) and the number of black spots in each section was compared using Wilcoxon matched-paired test (Zar, 1999).

We compared the growth type of parasitized and non-parasitized fish ($n = 107$ and 57 , respectively, for *A. aff. fasciatus*) estimating the parameters of the potential relationship $W_T = a S_L^b$, where W_T is total weight and S_L is standard length (Ricker, 1973), by a linear regression after data logarithmic transformation. We tested whether fish growth was statistically different between groups, by t-tests with $\alpha = 0.05$ (Mayrat, 1970; Ricker, 1973; Ricker, 1975).

RESULTS

A total of 2235 fish were collected, corresponding to 27 species and five Orders. Only two species, of the Characidae family, presented black spot disease: *Astyanax aff. fasciatus* (Cuvier, 1819) ("mojarra") ($n = 164$) and *Oligosarcus jenynsii* (Günther, 1864) ("dientudo") ($n = 2$). One hundred and five individuals of *A. aff. fasciatus* (prevalence = 63 %, mean intensity = 7) and both individuals of *O. jenynsii* presented black spot disease. Therefore, the temporal variation and its correlation with environmental and host's parameters were analyzed only for *A. aff. fasciatus*.

The results for prevalence, mean abundance, and intensity of black spot disease in *A. aff. fasciatus*, is shown in Table 1. The Kruskal-Wallis test did not show significant differences for abundance temporal variations ($H_{5,150} = 6.85; p = 0.23$)

Table 1. Summary statistics of black spot disease in *Astyanax aff. fasciatus* (prevalence, abundance and intensity) from Cañada del Dragón stream, SD, standard deviation, n , number of individuals captured. *Resumen estadístico de la enfermedad del punto negro en Astyanax aff. fasciatus (prevalencia, abundancia e intensidad) del arroyo Cañada del Dragón, SD, desvío estándar, n, número de individuos capturados.*

Sampling Date	Prevalence % infected fish (n)	Abundance		Intensity	
		Mean \pm SD	Range	Mean \pm SD	Range
July	66.6 (9)	6.1 \pm 8.4	0-23	9.8 \pm 8.9	1-23
September	66.6 (18)	1.8 \pm 2.7	0-8	2.8 \pm 2.2	1-8
November	63.1 (65)	3.6 \pm 6.7	0-33	5.8 \pm 7.7	1-33
February	60.4 (48)	3.9 \pm 8.3	0-52	6.6 \pm 9.8	1-52
April	77.8 (18)	10.5 \pm 14.7	0-51	13.7 \pm 15.5	1-51
June	83.3 (6)	7.3 \pm 8.1	0-21	8.8 \pm 8.1	1-21

and intensity ($H_{5,104} = 9.36; p = 0.10$). The Proportion test did not show significant differences for prevalence's temporal variation ($p > 0.05$).

The physico-chemical parameters analyzed (Tables 2 and 3) showed a significant temporal variation (Kruskal Wallis test, $p < 0.05$), but did not show a significant correlation with black spot intensity (Spearman r , $p < 0.05$).

We found no significant correlation between intensity of the disease and host's parameters (standard and total length, and weight). However, we found significant differences in the intensity of black spot between sections of the fish, particularly ventral (median = 2) and dorsal region (median = 1) (Wilcoxon test, $t = 1561.5, p < 0.05$).

The regressions for the two fish groups (parasitized and non-parasitized) were:

1) Parasitized fishes:

$$\log W_T = \log -1.44 (\pm 0.03) + 2.85 (\pm 0.04) \log S_L$$

February	12	138.4	34.9	15.7	5.4	2.7	1.6
April	12	151.6	36.4	27.2	12.7	3.3	1.4
June	12	118.6	54.75	16.4	11.4	3.7	3.6

2) Non-parasitized fishes:

$$\text{Log } W_T = \log -1.44(\pm 0.04) + 2.84(\pm 0.06) \log S_L$$

Standard errors are shown in parenthesis. The allometric coefficient values did not differ significantly between the fish groups (Student test, $p < 0.05$).

DISCUSSION

From a total of twenty-seven species, only two, *A. aff. fasciatus* and *O. jenynsii*, were infected with digenic trematodes, which could indicate a high specificity for the secondary host (de Kinkelin *et al.*, 1985) and/or ecological characteristics of these fish that make them more susceptible (Ondracková *et al.*, 2002). However, other species present in Cañada del Dragón stream with ecological characteristics similar to *A. aff. fasciatus*, such as other small non-migratory Characiformes, (“mojarras”) *Cheirodon interruptus* (Jenyns, 1842), *Bryconamericus iheringii* (Boulenger, 1887), and *Hyphessobrycon luetkenii* (Boulenger, 1887), did not present black spot disease. On the other hand, in other streams and creeks of the Santa Lucía River basin Arroyo Colorado, Cañada del Colorado, Cañada de las Conchillas, Arroyo Las Piedras, and Cañada del Juncal, (unpublished data), we have detected black spots in species collected in this study such as “madrecita” *Cnesterodon decemmaculatus* (Jenyns, 1842), “overito” *Jenynsia multidentata* (Jenyns, 1842) (Cyprinodontiformes), and

“mojarra” *B. iheringii* (Characiformes). These differences can be due to the presence of different parasites in the streams sampled, or to environmental characteristics causing differential infection susceptibility in fish species. The low catches of *O. jenynsii* prevented the evaluation of the prevalence and intensity of the black spot disease. Considering that *O. jenynsii* is a common species in our freshwater ecosystems (Ringuelet *et al.*, 1967), we believe that its susceptibility to black spot disease should be further evaluated.

The prevalence, abundance, and intensity of black spot disease in *A. aff. fasciatus*, did not show seasonal changes. On the contrary, Chubb (1979) found seasonal changes in prevalence and abundance, related to cercarial emergence with higher water temperatures. Nevertheless, the seasonal changes in black spot abundance and prevalence can be masked as old infections (Dönges, 1964). We found the greatest intensity of black spots in the ventral region of the fish. The differential distribution of metacercariae, may be affected by behavior and habitat of hosts (snails and fish) (Ondracková *et al.*, 2002). In this sense, Ringuelet (1975) described the Tetragonopterides, to which *A. aff. fasciatus* belongs, as a group of little fish that inhabit pools and vegetated zones. However, we have often captured *A. aff. fasciatus*, *O. jenynsii* and different snail species (i.e. *Heleobia* sp. and *Pomacea* sp.) in riffles and non-vegetated zones in the Cañada del Dragón stream. We hypothesize that the presence of potentially-infected snails over bare sediment, can explain the spatial pattern of the infection on the fish: the

parasites would be released from the bottom of the water column and reach the ventral region of the fish easier than other sections of the animals.

We found no differences in growth, between infected and non infected fish, which indicates a neutral effect of this parasite on *Astyanax aff. fasciatus*, at least over this variable. As it does not affect growth, it is also possible that it does not cause an effect at the population level in the $W_T - L_S$ relationship.

Our results suggest that, a high susceptibility of *Astyanax aff. fasciatus* to black spot disease, and/or a high specificity of the parasite occurs in the Cañada del Dragón stream. This is not reflected in several host's parameters (total and standard length and weight), which only show higher infection in the ventral part of the fish. The infected fish did not seem affected, at least concerning their growth.

Future studies will be addressed to determine whether the black spot disease detected in different fish species from the Santa Lucia River basin is caused by the same species of Digenea. This would help us to understand whether the patterns of infection in this basin are due to a species-specific relationship between the parasite and the host, or due to environmental characteristics related to water quality.

ACKNOWLEDGEMENTS

Authors wish to thank Alejandro D'Anatro, Esteban Charbonier, Marcelo Loureiro, and Lucía Boccardi for technical assistance during data collection. Also, we would like to thank Rodrigo Ponce de Leon, Marcelo Loureiro, Carlos Iglesias, and Mariana Meerhoff for the critical revision of the manuscript. We are also grateful to the anonymous referees which helped to improve earlier versions of this manuscript.
