Abstract

Scattering of electromagnetic (EM) waves by many small impedance particles (bodies), embedded in a homogeneous medium, is studied. Physical properties of the particles are described by their boundary impedances. The limiting equation is obtained for the effective EM field in the limiting medium, in the limit $a \rightarrow 0$, where a is the characteristic size of a particle and the number $M(a)$ of the particles tends to infinity at a suitable rate. The proposed theory allows one to create a medium with a desirable spatially inhomogeneous permeability. The main new physical result is the explicit analytical formula for the permeability $\mu(x)$ of the limiting medium. The computational results confirm a possibility to create the media with various distributions of $\mu(x)$.

Keywords: EM Wave Scattering, Permeability, Modeling Results.

1 Introduction

A theory of electromagnetic (EM) wave scattering by many small impedance particles (bodies) embedded in a homogeneous medium with a constant permittivity $\varepsilon_0 > 0$, permeability $\mu_0 > 0$ and, possibly, constant conductivity $\sigma_0 \geq 0$ is applied for creating a media with a prescribed permeability. The computational procedure for numerical solution of the scattering problem were developed in [1].

In [9] there is a mathematical analysis of the Maxwell's equations, and in [10] theory of the wave scattering by obstacles is developed.

The small particles are embedded in a finite domain D . The medium, created by the embedding of the small particles, has new physical properties. In particular, it has a spatially inhomogeneous magnetic permeability $\mu(x)$, which can be controlled by the choice of the boundary impedances of the embedded small particles and their distribution density. An analytic formula for the permeability of the new medium is obtained (see Subsection 2.3).

Although the initial medium has a constant permeability μ_0 , the limiting medium, obtained as a result of embedding many small particles with prescribed boundary impedances, has a non-homogeneous permeability which is expressed analytically in terms of the distribution density of the small particles and their boundary impedances. Therefore, a new physical phenomenon is predicted theoretically, namely, appearance of a spatially inhomogeneous permeability as a result of embedding of many small particles whose physical properties are described by their boundary impedances.

We assume that in any sub-domain Δ , the number $N(\Delta)$ of the embedded particles is given by the formula:

$$\mathcal{N}(\Delta) = \frac{1}{a^{2-\kappa}} \int_{\Delta} N(x) dx [1+o(1)], \quad a \rightarrow 0, \quad (1)$$

where $N(x) \geq 0$ is a continuous function, vanishing outside of the finite domain D in which small particles (bodies) are distributed, $\kappa \in (0, 1)$ is a number that one can choose as one wishes, and the boundary impedances of the small particles are defined by the formula:

$$\zeta_m = \frac{h(x_m)}{a^\kappa}, \quad x_m \in D_m, \quad \operatorname{Re} h(x) \geq 0, \quad (2)$$

where x_m is a point inside m -th particle, and $h(x)$ is a continuous function vanishing outside D which satisfies only the physical restriction $\operatorname{Re} h(x) \geq 0$. The function h , used in our numerical examples satisfies this restriction. The impedance boundary condition on the surface S_m of the m -th particle D_m is $E^t = \zeta_m [H^t, N]$, where $E^t(H^t)$ is the tangential component of $E(H)$ on S_m , and N is the unit normal to S_m , pointing out of D_m .

Since one can choose the functions $N(x)$ and $h(x)$, one can create a desired magnetic permeability in D . This is a novel idea proposed originally in [14], [15]. It has led to a recipe for creating materials with a desired refraction coefficient in [19], [20]. [21].

Materials with negative permittivity and permeability are of interest in applications, see [11], [23], [24]).

We also derive an analytic formula for the refraction coefficient of the medium in D created by the embedding of many small particles. An equation for the effective EM field in the limiting medium is derived. This medium is created when the size a of small particles tends to zero while the total number $M = M(a)$ of the particles tends to infinity at a suitable rate.

The refraction coefficient $n^2(x)$ in the limiting medium is spatially inhomogeneous.

The proposed theory may be viewed as a "homogenization theory", but it differs from the usual homogenization theory (see, e.g., [3], [10], [5], and references therein) in several respects: we do not assume any periodic structure in the distribution of small bodies, our problem does not have a discrete spectrum, our operators are non-selfadjoint, to mention some of the differences. The ideas, methods, and techniques are also quite different from the usual methods. These ideas are similar to the ideas developed in papers [15], [16], where scalar wave scattering by small bodies was studied. More on this one can find in the forthcoming monograph [22].

However, the scattering of EM waves brought new technical difficulties which are resolved in this paper. The difficulties come from the vectorial nature of the boundary conditions. Our approach is valid for small particles of arbitrary shape, but for simplicity we assume that the small bodies are balls of radius a [18].

2 EM Wave Scattering by Many Small Particles

2.1 Statement of Problem

It is assumed that many small bodies D_m , $1 \leq m \leq M$, are embedded in a homogeneous medium with constant parameters ε_0 , μ_0 . Let $k^2 = \omega^2 \varepsilon_0 \mu_0$, where ω is the frequency. The arguments remain valid if one assumes that the medium has a constant conductivity $\sigma_0 > 0$. In this case ε_0 is replaced by $\varepsilon_0 + i \frac{\sigma_0}{\omega}$. Denote by $[E, H] = E \times H$ the cross product of two vectors, and by $(E, H) = E \cdot H$ the dot product of two vectors.

EM wave scattering problem consists of finding vectors E and H satisfying the Maxwell equations:

$$\nabla \times E = i\omega\mu_0 H, \quad \nabla \times H = -i\omega\varepsilon_0 E \quad (3)$$

in $D := \mathbb{R}^3 \setminus \bigcup_{m=1}^M D_m$, the impedance boundary conditions:

$$[N, [E, N]] = \zeta_m [N, H] \quad (4)$$

on S_m , $1 \leq m \leq M$, and the radiation conditions:

$$E = E_0 + v_E, \quad H = H_0 + v_H, \quad (5)$$

where ζ_m is the impedance, N is the unit normal to S_m pointing out of D_m , E_0, H_0 are the incident fields satisfying equations (3) in all of \mathbb{R}^3 . The usual form of impedance boundary condition is $E^t = \zeta [N, H^t]$, where $E^t := [N, [E, N]]$ is the tangential component of E on S . Thus, $[N, H^t] = [N, [N, [H, N]]] = [N, H]$, because $[N, [H, N]] = H - NH \cdot N$, and $[N, N] = 0$. This justifies the impedance boundary condition (4) we use. The impedance boundary condition is widely applicable in physics. We assume in this paper that the impedance ζ is a constant, $\text{Im} \zeta \geq 0$. In the literature (see, for example, [9]) one may see the

impedance boundary condition with $[H^t, N]$ in place of our $[N, H^t]$. This is due to the fact that N in [9] is the unit normal to S pointing into D , while we use N pointing out of D .

One often assumes that the incident wave is a plane wave, i.e., $E_0 = \beta e^{ik\alpha \cdot x}$, β is a constant vector, $\alpha \in S^2$ is a unit vector, S^2 is the unit sphere in \mathbb{R}^3 , $\alpha \cdot \beta = 0$, v_E and v_H satisfy the radiation condition:

$$r\left(\frac{\partial v}{\partial r} - ikv\right) = o(1). \quad (6)$$

Impedance ζ_m is assumed to be a constant, $\text{Re}\zeta_m \geq 0$, so that

$$\text{Re}(\zeta_m E^t, E^t) \geq 0 \quad \forall E^t \in T_m, \quad (7)$$

where T_m is the set of all tangential to S_m continuous vector fields such that $\text{Div}E^t = 0$, where Div is the surface divergence, and E^t is the tangential component of E . Smallness of D_m means that $ka \ll 1$, where

$$a = 0.5 \max_{1 \leq m \leq M} \text{diam}D_m.$$

Our definition of E^t is:

$$E^t = E - N(E, N) = [N, [E, N]]. \quad (8)$$

This definition differs from the one used often in the literature, namely, from the definition $E^t = [N, E]$. Since

$$H = \frac{\nabla \times E}{i\omega\mu_0}, \quad (9)$$

one gets

$$\nabla \times \nabla \times E = k^2 E \quad \text{in } D, \quad (10)$$

and the impedance boundary condition is

$$[N, [E, N]] = \frac{\zeta_m}{i\omega\mu_0} [N, \nabla \times E] \quad (11)$$

on S_m , $1 \leq m \leq M$.

Thus, we have reduced problem (3)-(5) to finding one vector $E(x)$ satisfying the impedance boundary condition (11). If $E(x)$ is found, then $H = \frac{\nabla E}{i\omega\mu_0}$.

2.2 Finding the Solution

Let us look for E of the form

$$E = E_0 + \sum_{m=1}^M \nabla \times \int_{S_m} g(x, t) \sigma_m(t) dt, \quad (12)$$

$$g(x, y) = \frac{e^{ik|x-y|}}{4\pi|x-y|},$$

where $t \in S_m$ and dt is an element of the area of S_m , $\sigma_m(t) \in T_m$. This E for any continuous $\sigma_m(t)$ solves equation (10) in D because E_0 solves (10).

Define the *effective field* $E_e(x) = E_e^m(x) = E_e^{(m)}(x, a)$, acting on the m -th body D_m , by the formula:

$$E_e(x) = E(x) - \nabla \times \int_{S_m} g(x, t) \sigma_m(t) dt := E_e^{(m)}(x), \quad (13)$$

where it is assumed that x is in a neighborhood of S_m , but $E_e(x)$ is defined for all $x \in \mathbb{R}^3$. Let $x_m \in D_m$ be a point inside D_m , and $d = d(a)$ be the distance between two neighboring small bodies. Let us assume that

$$\lim_{a \rightarrow 0} \frac{a}{d(a)} = 0, \quad \lim_{a \rightarrow 0} d(a) = 0. \quad (14)$$

It is proved in [15] that $E_e(x, a)$ tends to a limit $E_e(x)$ as $a \rightarrow 0$, and $E_e(x)$ is a twice continuously differentiable function.

Let us assume that in any sub-domain Δ , the number $\mathcal{N}(\Delta)$ of the embedded bodies D_m is given by formula (1), and boundary impedances ζ_m of small particles are defined by formula (2).

Let us write (12) as

$$E(x) = E_0(x) + \sum_{m=1}^M [\nabla_x g(x, x_m), Q_m] + \sum_{m=1}^M \nabla \times \int_{S_m} (g(x, t) - g(x, x_m)) \sigma_m(t) dt, \quad (15)$$

where

$$Q_m := \int_{S_m} \sigma_m(t) dt. \quad (16)$$

Since $\sigma_m = O(a^{-\kappa})$, one has $Q_m = O(a^{2-\kappa})$. One wants to prove that the second sum in (15) is negligible compared with the first one. This proof is based on several estimates. These estimates show that one may neglect the second sum in (15), see [18], and write

$$E_e(x) = E_0(x) + \sum_{m=1}^M [\nabla_x g(x, x_m), Q_m] \quad (17)$$

with an error that tends to zero under our assumptions as $a \rightarrow 0$, and when $|x - x_j| \sim a$ then the term with $m = j$ in the sum (17) should be dropped according to the definition of the effective field. We will show that the limit of the effective field, as $a \rightarrow 0$ does exist and solves equation (21), see below.

As $a \rightarrow 0$, the sum in (17) converges to the integral

$$E(x) = E_0(x) + \nabla \times \int_D g(x, y) N(y) Q(y) dy, \quad (18)$$

where $Q(y)$ is the function uniquely defined by the formula

$$Q_m = Q(x_m)a^{2-\kappa}, \quad (19)$$

where $Q(y)$ is a continuous function in D . This function $Q(y)$ is defined uniquely, because, as $a \rightarrow 0$ the set of points $\{x_m\}_{m=1}^M$ becomes dense in D . The physical meaning of vector $E(x)$ in equation (18) is clear: this vector is the limit of the effective field $E_e(x)$ as $a \rightarrow 0$, and $N(x)$ is the function from equation (1).

The function $Q(y)$ can be expressed in terms of E :

$$Q(y) = \frac{8\pi i}{3\omega\mu_0} h(y)(\nabla \times E)(y). \quad (20)$$

The factor $\frac{8\pi}{3}$ appears if D_m are balls. Otherwise a tensorial factor c_m , depending on the shape of S_m , should be used in place of $\frac{8\pi}{3}$.

From equations (18) and (20) one obtains

$$E(x) = E_0(x) + \frac{8\pi i}{3\omega\mu_0} \nabla \times \int_D g(x, y) h(y) N(y) \nabla \times E(y) dy. \quad (21)$$

2.3 Explicit Formula for Permeability of Resulting Medium

Let us derive main physical conclusion from equation (21). Applying the operator $\nabla \times \nabla \times$ to (21) yields

$$\begin{aligned} \nabla \times \nabla \times E &= k^2 E_0(x) + \frac{8\pi i}{3\omega\mu_0} \nabla \times (\text{grad div} - \\ &\nabla^2) \int_D g(x, y) h(y) N(y) \nabla \times E(y) dy \\ &= k^2 E(x) + \frac{8\pi i}{3\omega\mu_0} h(x) N(x) \nabla \times \nabla \times E + \frac{8\pi i}{3\omega\mu_0} [\nabla(h(x)N(x)), \nabla \times E(x)]. \end{aligned} \quad (22)$$

Here we have used the formula $\nabla \times \text{grad} = 0$ and the equation

$$-\nabla^2 g(x, y) = k^2 g(x, y) + \delta(x - y), \quad (23)$$

and took into account that $h(x)$ is a scalar function by the assumption.

It follows from (22) that

$$\nabla \times \nabla \times E = K^2(x)E + \frac{\frac{8\pi i}{3\omega\mu_0}}{1 - \frac{8\pi i}{3\omega\mu_0} h(x)N(x)} [\nabla(h(x)N(x)), \nabla \times E(x)], \quad (24)$$

where

$$K^2(x) = \frac{k^2}{1 - \frac{8\pi i}{3\omega\mu_0} h(x)N(x)}, \quad k^2 = \omega^2 \varepsilon_0 \mu_0. \quad (25)$$

If one uses the equation

$$\nabla \times E = i\omega\mu(x)H, \quad \nabla \times H = -i\omega\varepsilon(x)E,$$

then

$$\nabla \times \nabla \times E = \omega^2\varepsilon(x)\mu(x)E + \left[\frac{\nabla\mu(x)}{\mu(x)}, \nabla \times E \right]. \quad (26)$$

Comparing this equation with (24), one can identify the last term in (24) as coming from a variable permeability $\mu(x)$. This $\mu(x)$ appears in the limiting medium due to the boundary currents on the surfaces S_m , $1 \leq m \leq M$. These currents appear because of the impedance boundary conditions (11).

Let us identify the permeability $\mu(x)$. Denote

$$\Psi(x) := 1 - \frac{8\pi i}{3\omega\mu_0} h(x)N(x). \quad (27)$$

Let $\varepsilon(x) = \varepsilon_0$, $\varepsilon_0 = \text{const}$, and define

$$\mu(x) := \frac{\mu_0}{\Psi(x)}. \quad (28)$$

Then $K^2 = \omega^2\varepsilon_0\mu(x)$, and

$$\frac{\nabla\mu(x)}{\mu(x)} = \frac{\nabla\Psi(x)}{\Psi(x)}.$$

Consequently, formula (24) has a clear physical meaning: the electromagnetic properties of the limiting medium are described by the variable permeability:

$$\mu(x) = \frac{\mu_0}{\Psi(x)} = \frac{\mu_0}{1 - \frac{8\pi i}{3\omega\mu_0} h(x)N(x)}, \quad (29)$$

and the limiting medium is described by the new refraction coefficient $K^2 = \omega^2\varepsilon_0\mu(x)$.

3 Derivation of a Linear Algebraic System for Vectors P_m

In this Section a numerical method is developed for solving many-body wave scattering problem when the scatterers (bodies) are small in comparison with the wavelength. The method consists of a derivation of a linear algebraic system for finding vectors

$$P_m = (\nabla \times E)(x_m), \quad 1 \leq m \leq M. \quad (30)$$

If P_m are found, then by formulas (20) and (19) one finds

$$Q_m = \frac{8\pi i}{3\omega\mu_0} a^{2-\kappa} h(x_m) P_m \quad (31)$$

and, by formula (17), the field $E(x)$.

Let us derive linear algebraic system for finding P_m . Apply the operator $\nabla \times$ to equation (21), let $x = x_j$, $1 \leq j \leq M$, and replace $\sum_{m=1}^M$ by the sum $\sum_{m \neq j, m=1}^M$.

Then one obtains

$$P_j = P_{0j} + \frac{8\pi i}{3\omega\mu_0} a^{2-\kappa} \sum_{m \neq j, m=1}^M \{k^2 g(x, x_m) h(x_m) P_m + h(x_m) (P_m, \nabla) \nabla g(x, x_m)\} |_{x=x_j} \quad (32)$$

where $1 \leq j \leq M$, and

$$P_{0j} := (\nabla \times E_0)(x_j), \quad P_j = (\nabla \times E)(x_j), \quad 1 \leq j \leq M. \quad (33)$$

Equation (32) is a linear algebraic system for finding P_m .

4 Numerical Results

The numerical calculations demonstrate the dependence of convergence of the iterative process for solving LAS (34)-(36) on the parameters a , d , and M . This allows one to establish the limits of the asymptotic approach depending on the parameters of problem and to investigate the dependence of the created permeability on a and M .

Part of the numerical results justifies the assumptions $\text{Div} E_t = 0$ and $\text{Div} \sigma_m = 0$, which can be used for obtaining the asymptotic solution (17).

The numerical examples demonstrate a possibility to create media with piecewise-constant permeability.

4.1 Checking the Applicability of Asymptotic Approach

The numerical experiments were carried out for checking the convergence of solution to LAS (32). It contains the unknown values of P_j on the left-hand part, and on the right-hand part in the terms $(P_m, \nabla) \nabla g(x, x_m)$. The detailed form of LAS (32) can be given by the formulas:

$$P_{jx} = P_{0x} + \frac{8\pi i}{3\omega\mu_0} a^{2-\kappa} \sum_{m \neq j, m=1}^M h(x_m) [-P_{mx} \times (\frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}) g(x, x_m) + P_{my} \frac{\partial^2}{\partial x \partial y} g(x, x_m) + P_{mz} \frac{\partial^2}{\partial x \partial z} g(x, x_m)], \quad (34)$$

$$P_{jy} = P_{0y} + \frac{8\pi i}{3\omega\mu_0} a^{2-\kappa} \sum_{m \neq j, m=1}^M h(x_m) [-P_{my} \times (\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2}) g(x, x_m) + P_{mx} \frac{\partial^2}{\partial x \partial y} g(x, x_m) + P_{mz} \frac{\partial^2}{\partial y \partial z} g(x, x_m)], \quad (35)$$

$$\begin{aligned}
P_{jz} = P_{0z} + \frac{8\pi i}{3\omega\mu_0} a^{2-\kappa} \sum_{m \neq j, m=1}^M h(x_m) [-P_{mz} \times \\
(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2})g(x, x_m) + P_{mx} \frac{\partial^2}{\partial x \partial z} g(x, x_m) + P_{my} \frac{\partial^2}{\partial y \partial z} g(x, x_m)],
\end{aligned} \tag{36}$$

where P_{jx} , P_{jy} , and P_{jz} are the x -, y -, and z -components of vectors P_j , respectively. One can see from (34)-(36) that for determination of P_{jx} component it is necessary to know the remaining components P_{jy} and P_{jz} . The following iterative process is proposed for solving LAS (34)-(36):

Step 1. Let $n = 0$ is number of iteration.

Step 2. The initial approximations P_{my_n} and P_{mz_n} are prescribed (or given if $n \neq 0$), and vector $P_{jx_{n+1}}$ is determined by solving (34).

Step 3. Having $P_{mx_{n+1}}$ and P_{mz_n} , we determine $P_{my_{n+1}}$ from (35).

Step 4. We determine $P_{mz_{n+1}}$ with know $P_{mx_{n+1}}$, $P_{my_{n+1}}$ solving LAS (36).

Step 5. If the inequalities

$$|P_{mx_{n+1}} - P_{mx_n}| < \varepsilon, \tag{37}$$

$$|P_{my_{n+1}} - P_{my_n}| < \varepsilon, \tag{38}$$

$$|P_{mz_{n+1}} - P_{mz_n}| < \varepsilon, \tag{39}$$

are satisfied (there ε is the given accuracy of calculations), we finish the iterative procedure. Otherwise, we return to *Step 2*, by setting $n = n + 1$.

It is obvious that the inequalities are not checked in the first iteration, because P_{mx_0} is not given.

It was established that convergence of the above iterative process depends on the ratio d to a at the fixed value of M . The calculations for a series of d show that the value $d/a \approx 10$ is the lowest one, that provides the convergence of the iterative method used. The iterative procedure for solving LAS (34)-(36) for $d/a < 10$ becomes unstable and does not converge if d/a increase, but there are special cases when the value of the threshold is smaller.

In Fig. 1, the rate of convergence, depending on the radius a of particle at the fixed number of particles in D and the distance between them, is shown for P_{mx} and P_{my} components. The relative error of the solution

$$RE = \frac{\|S_{n+1} - S_n\|}{\|S_{n+1}\|} \tag{40}$$

is put along the y axis, and number of iteration n is put along the x axis. Here $S_n := \{P_{mx_n}, P_{my_n}, P_{mz_n}\}$, and we use the sign $\|\cdot\|$ of the norm because P_{mx_n} , P_{my_n} , and P_{mz_n} are the matrices. The number of particles is equal to 10^3 , and the distance between them is equal to 0.5. The linear distances (a and d) are measured in cm (1×10^{-2} m). The maximal error is observed in the first iteration. This error is equal to 0.075 and 0.004 for $a = 0.08$ and $a = 0.01$,

Figure 1: The relative error versus number n of iteration for P_{mx} component

respectively. The error decreases quickly and in the third iteration it is equal to 2×10^{-4} and 5.6×10^{-9} for the above values of a .

The relative error for the P_{my} component behaves similarly, although their values are slightly smaller: they are equal to 0.066 and 0.003 for $a = 0.08$ and $a = 0.01$, respectively.

The properties of the resulting medium depends on the radius a of the particles when M and d are fixed. In Table 1, the permeability μ , wave number k , and maximal value of amplitude E_x of the scattered field are given for the values of a , considered in the previous example. The values of μ are normalized on the quantity $\mu_0 = 4\pi \times 10^{-7} \text{H} \times \text{m} \approx 1.256 \times 10^{-6} \text{H} \times \text{m}$. At such a normalization, $\mu_0 = 1$. One can see that value of μ is changed by 14% for $a = 0.01$ and by 58% for $a = 0.08$. The maximal value of the component E_x of the scattered field increased almost tenfold when a is changed from 0.01 to 0.08.

The iterative process becomes unstable as a grows, and this process does not converges if $d/a < 6$ at the considered values of M and d .

Table 1. The properties of resulting domain D at various a .

	$a = 0.01$	$a = 0.03$	$a = 0.05$	$a = 0.08$
μ	0.8641	0.6616	0.5345	0.4196
k	0.0930	0.0814	0.0731	0.0646
$\max(E_x)$	1.1569	1.5308	1.94191	2.61896

In Fig. 3, the values of the permeability μ are calculated by formula 29 and their dependence on a is shown. The value of $k = 10\text{m}^{-1}$ corresponds to the frequency $\omega = 30\text{MHz}$, while the radius a of the particles changes between the limits $1 \times 10^{-4}\text{m} \div 9 \times 10^{-4}\text{m}$, $h(x) = 10i$.

One can see that the values of μ for larger d are closer to the initial permeability $\mu_0 = 1$ of the medium without embedded particles. This is clear,

Figure 2: The relative error versus number n of iteration for P_{my} component

because as the values of d increase, the physical properties of D become closer to properties of the initial medium. The results shown for the values of d/a which assure the convergence of the proposed iterative process.

The results, presented in Fig. 4, demonstrate the change of μ for various d at the optimal physical parameters of D which guarantee the convergence of the iterative process for solving LAS (34)-(36). One can see that for the smaller d the permeability changes considerably. For example, at $d = 0.3$ and $a = 0.01$ the values of μ deviate from $\mu_0 = 1.0$ by 40%. This deviation decreases as d grows, and it does not exceed 5% at $d = 0.9$ for the considered range of a . The value of the function $h(x)$ influences the behavior of μ . The results shown in Fig. 5 demonstrate that the values of μ corresponding to the small $|\text{Im}h(x)|$ are closer to $\mu_0 = 1$, and the difference between μ and μ_0 grows if $|\text{Im}h(x)|$ increases. The convergence of the solution to LAS (34)-(36) depends on the values of $|\text{Im}h(x)|$. At the small values of d the convergence holds for small values of $|\text{Im}(h)|$ and the convergence region increases as the value of d increases.

The other characteristics of the field change if the radius a and the function $h(x)$ change. The amplitude of the scattered field E is one of such characteristics. In Fig. 6, the dependence of the maximum of the amplitude E_x of the scattered field on the radius a of the particles is shown. This amplitude grows if a increases. The increase of the amplitude is similar for various d and the amplitude changes almost linearly as the radius a of the particles grows. The amplitude increases at $d = 0.9$ more than ten times when ka increases from 0.01 up to 0.09. Referring to Fig. 3, one sees that the amplitude grows as a grows and the values of μ deviate from the initial value μ_0 .

4.2 Exactness of Asymptotic Formula (17)

It is important from the practical point of view to know how accurate is asymptotic formula (17). To answer on this question we carry out a series of computations related to the comparison of asymptotic formula (17) with the solution of EM wave scattering problem by Mie series, obtained in [2]. We consider here the particular case $M = 1$, because the EM wave scattering problem for one particle was considered there. Solution (52) in the form of Mie series is considered as the benchmark one. We use the formulas of transformation of the electrical field's spherical components into cartesian ones [7] because solution (52) is given in the spherical coordinates. The relative error is defined as $\|E_{52} - E_{17}\|/\|E_{52}\|$, where $\|\cdot\|$ is the sup norm, $E = (E_x, E_y, E_z)$. The subscript 52 indicates the solution obtained by Mie series (52) in [2], and subscript 17 indicates the solution obtained by asymptotic formula (17). The calculations are performed for series of radius a of particle and various functions $h(x)$.

In Fig. 7, the relative error of the E_x , E_y , and E_z components depending on the radius a of particles is shown for several distances r from the center of particle to the observation point, $k = 0.1$, $h(x) = 10i$. One can observe that the relative error is very sensitive to the radius a of particle. The maximal value of error is attained for E_x component at $a = 0.5$ and it is equal to 7.6%. The values of relative error for E_y and E_z components are 1.2% and 0.1%, respectively. The minimal values of error for all components are reached at $a = 0.1$ and they are equal to 0.2%, 0.1%, and 0.02% for E_x , E_y , and E_z , respectively. The relative error diminishes quickly as distance r grows. So, the maximal values of error for $r = 8.0$ are observed at $a = 0.5$ and they are equal to 2.1%, 0.3%, and 0.07% for E_x , E_y , and E_z components. This error does not exceed 0.06% at $a = 0.1$. The numerical calculations show that the relative error depends on the function

Figure 8: Relative error of E_x , E_y , and E_z components for various distances r to observation point, $h(x) = 100i$

$h(x)$ influencing the value of surface impedance ζ considerably. In Fig. 8, the values of relative error are shown for $h(x) = 100i$. It turned out that relative error increases too much. For example, its value for E_x component at $r = 8.0$ is equal to 25.1%, the values of this error for E_y and E_z components are a little smaller. In order to attain the relative error of the same order as in the previous example, it is necessary to increase the distance r approximately twice. So, the relative error of E_y component at $r = 10.0$ for $a = 0.5$ is equal to 5.7%; the minimal value of error at these r and a is reached for E_z component and it is equal to 0.5%. The maximal value of error at $r = 15.0$ is equal to 1.0% and 0.02% for $a=0.5$ and $a = 0.1$, respectively, and these values are attained for E_y component. The relative error for E_x and E_z components is smaller.

The obtained computational results testify the high accuracy of asymptotic formula (17) for the case of one particle. The relative error of (17) depends on the radius a of particle, distance r to point of observation (point in far zone), and function $h(x)$ influencing the value of surface impedance ζ .

4.3 Justification of Assumption $\text{Div}E_t = 0$

Is it possible to use the assumption $\text{Div}E_t = 0$ on the surfaces of the particles? This assumption is not justified theoretically. Therefore, the numerical justification of this assumption is of interest. We carry out a series of calculations which show that the equality $\text{Div}E_t = 0$ is satisfied with high accuracy. The derivatives $\frac{\partial E_x}{\partial x}$, $\frac{\partial E_y}{\partial y}$, and $\frac{\partial E_z}{\partial z}$ are replaced by the corresponding finite differences in the process of the numerical calculations of $\text{Div}E_t$.

First, the investigation of the dependence of the value of $\text{Div}E_t$ on the radius a of particles at a fixed distance d between them is done. The calculations are

Figure 9: Maximal value of $\text{Div}E_t$ versus radius a of particle

carried out for $M = 10^3$, $d = 0.5$, and $k = 0.1$. In Fig. 9, the maximal values of $\text{Div}E_t$ on the surface of the first, central, and last particles are shown. The numbering of particles starts from the left upper side of D and continues to its right lower side. One can see that the maximal value of $\text{Div}E_t$ does not exceed 6.4×10^{-3} , 3.7×10^{-3} , and 0.45×10^{-3} for the first, central, and last particles, respectively. In Fig. 10, the minimal values of the E_x and E_z components on the surface of the particles are shown. In this case, the values E_x and E_y practically coincide. Comparing the results in both Figures, one concludes that the values of $\text{Div}E_t$ does not exceed 2% in comparison with the corresponding values of E components. So, the relation $\max(\text{Div}E_t)/\min(E_{x,y,z})$ equals to 1.4×10^{-2} , 0.46×10^{-3} , and 2.5×10^{-2} for the first, central and the last particles, respectively, that is, part of $\text{Div}E_t$ on the particles' surfaces does not exceed 2.5% of the value of the E components. In Fig. 9, the maximal values of $\text{Div}E_t$ are presented. In fact, this value is two orders smaller, so the average value of $\text{Div}E_t$ is practically one order smaller than presented ones. The numerical results, presented in Fig. 11, demonstrate that the value of $\text{Div}E_t$ depends on the distance d between particles less, and this value becomes stable as d grows. The results are related to central particle, $M = 10^3$, $k = 0.1$. For example, the value of $\text{Div}E_t$ is equal to 2.8×10^{-4} for $d = 0.5$ and it stabilizes at the value 3.4×10^{-4} at $d > 1.2$ for $a = 0.05$. Similar behavior of $\text{Div}E_t$ is observed for $a = 0.03$ and $a = 0.01$. The maximal value of the ratio $\max(\text{Div}E_t)/\min(E_{x,y,z})$ is equal to 1.4% for the considered values of a and d . The value of $\text{Div}E_t$ slowly grows also as $d/a \leq 7$.

The dependence of $\text{Div}E_t$ on the number M of particles for various a at the fixed value of d is shown in Fig. 12. Here $k = 0.1$, $d = 0.5$. The maximal value of $\text{Div}E_t$ is observed at $M = 125$ and it is equal to 2.0×10^{-3} , 1.15×10^{-3} ,

Figure 10: Minimal values of E_x and E_z components versus radius a of particle

and 0.33×10^{-3} for $a = 0.05$, $a = 0.03$, and $a = 0.01$, respectively. This value becomes a local minimum for $M = 9^3$, it grows slowly as M increases and becomes stable at $M > 15 \times 10^3$. The values of $\text{Div}E_t$ at this M are equal to 1.62×10^{-3} , 0.73×10^{-3} , and 0.09×10^{-3} for $a = 0.05$, $a = 0.03$, and $a = 0.01$, respectively. The maximal value of the ratio $\max(\text{Div}E_t)/\min(E_{x,y,z})$ in the above calculations does not exceed 1.85%.

Consequently, the obtained numerical results show that the condition $\text{Div}E_t = 0$ on the surfaces of the particles is satisfied with high accuracy.

4.4 Justification of the Assumption $\text{Div}\sigma_m = 0$

To check this assumption numerically we define the function σ_m as the solution to integral equation of the second kind obtained in [21]

$$\sigma_m(t) = A\sigma_m(t) + f_m(t), \quad (41)$$

where $f_m = 2[f_e(s), N_s]$ and

$$f_e(s) = [N_s, [E_e(s), N_s]] - \frac{\zeta_m}{i\omega\mu_0}[\nabla \times E_e(s), N_s], \quad (42)$$

$$A\sigma_m = 2\zeta_m i\omega\varepsilon_0 [N_s, [N_s, \int_{S_m} g(s, t)\sigma_m(t)]dt - \int_{S_m} [N_s, [\nabla_s g(s, t), \sigma_m(t)]]dt]. \quad (43)$$

This equation is solved by the collocation method [17]. The corresponding LAS has the form similar to (34)-(36).

Figure 11: Maximal value of $\text{Div} E_t$ versus distance d between particles

Figure 12: Maximal value of $\text{Div} E_t$ versus number M of particles

First, we investigate the dependence of $\text{Div}\sigma_m$ on the radius a of particles at the fixed distance d between them. The respective results are shown in Fig. 13. The maximal value of $\text{Div}\sigma_m$ is shown for the first, central and last particles, total number of particles $M = 10^3$, $k = 0.1$, $d = 0.5$. The maximal value of $\text{Div}\sigma_m$ is given for the central particle at $a = 0.01$ and it is equal to 0.0088. This value is slightly smaller for the last and first particles (0.0055 and 0.0043, respectively). It decreases slowly as a grows and becomes stable at $a > 0.5$.

Figure 13: Maximal value of $\text{Div}\sigma_m$ versus radius a of particle

In Fig. 14, the θ -th and φ -th components of σ_m are presented. Use of the spherical components for calculation of $\text{Div}\sigma_m$ is more convenient here. The $\sigma_{m\varphi}$ component is practically the same for the first, central and the last particles; therefore it is shown only for the central particle. One can see that the minimal value of $\sigma_{m\varphi}$ and $\sigma_{m\theta}$ components are two orders larger than the values of $\text{Div}\sigma_m$. For example, the ratio $\max(\text{Div}\sigma_m)/\min(\sigma_{m\theta})$ is equal to 0.65%, 0.48%, and 0.41% for the central, last and first particles, respectively, at $a = 0.01$. This value for $\max(\text{Div}\sigma_m)/\min(\sigma_{m\varphi})$ equals to 2.42%, 1.51%, and 1.18%, that is the values of $\text{Div}\sigma_m$ do not exceed several percents in comparison with the corresponding values of σ_m components.

The dependence of the maximal value of $\text{Div}\sigma_m$ on the distance d between particles for several values of radius a is shown in Fig. 15 for the central particle. The numerical results confirm that the values of the maximum of $\text{Div}\sigma_m$ are at least two orders less than the values of $\sigma_{m\varphi}$ and $\sigma_{m\theta}$ components presented in Fig. 17. So, the ratio $\max(\text{Div}\sigma_m)/\min(\sigma_{m\theta})$ is equal to 0.41%, 0.38%, and 0.32% for $a = 0.01$, $a = 0.03$, and $a = 0.05$, respectively, at $d = 0.5$. This value is equal to 0.18%, 0.18%, and 0.17% for the above a at $d = 1.0$. One can see that this relation decreases slowly as d increases. As for $\text{Div}E_t$, the quantity

Figure 14: Minimal values of σ_m components versus radius a of particle

$\text{Div}\sigma_m$ depends less on d at fixed a than on a at fixed d .

The dependence of $\max(\text{Div}\sigma_m)$ on the number M of particles for several values of a at fixed d is shown in Fig. 17. Parameters $d = 0.5$, $k = 0.1$. The greatest value of $\text{Div}\sigma_m$ is observed for $M = 5^3$ at $a = 0.01$ and it is equal to 0.0087; this value decreases as M grows and it is equal to 0.0016 at $M = 20^3$. This change is less for $a = 0.03$ and $a = 0.05$. The values of $\text{Div}\sigma_m$ are 0.0033 and 0.0020 for $M = 5^3$, and 0.0011 and 0.0006 for $M = 20^3$. As example, the value of $\max(\text{Div}\sigma_m)/\min(\sigma_{m\theta})$ for $d = 1.0$ is equal to 0.63% for $M = 5^3$ and 0.21% for $M = 20^3$ at $a = 0.03$, and it is equal to 0.56% for $M = 5^3$ and 0.17% for $M = 20^3$ at $a = 0.05$. These numerical results show that maximal value of the ratio $\max(\text{Div}\sigma_m)/\min(\sigma_{m\theta}, \sigma_{m\varphi})$ does not exceed a fraction of a percent. This confirms that the equality $\text{Div}\sigma_m = 0$ on the surface of particles can be used in numerical calculations.

4.5 Creating Media with Piecewise-constant Distribution of Permeability

The proposed approach allows one to create a media with a piecewise-constant magnetic permeability μ . Such permeability can be realized either by embedding various numbers M_m of particles into sub-domains Δ_m or by the variation of the function $h(x_m)$ in these sub-domains.

Both approaches have their advantages depending on the parameters M , a , and d of D . In engineering it is often useful to have constant distribution of μ along certain direction (for example, along z - and y -axis), and piecewise-constant μ in the direction of x -axis.

In Fig. 18, such μ is formed by embedding various numbers of particles

Figure 15: Maximal value of $\text{Div}\sigma_m$ versus distance d between particles

M_m in sub-domains Δ_m , ($m = 1, 2, 3$): $M_1 = 11 \times 11 \times 4$, $M_2 = 9 \times 9 \times 3$, $M_3 = 11 \times 11 \times 4$, respectively. At these values of M_m , the values of permeability are equal to 0.9229 in sub-domains Δ_1 and Δ_3 , and the permeability is equal to 0.9410 in sub-domain Δ_2 . Such distribution of particles in the medium allows one to reach a difference in the μ values in the range of 2.2%, the minimal deviation of μ from the μ_0 is 5.9%. In order to increase the difference μ_m for various D_m it is necessary to increase the difference between M_m .

The distributions of μ obtained above allows one to form different distribution of E_x and E_y component of the total field. In Figs. 19 and 20, these components are shown in the far zone of D ($d_f = 20l_D$), where l_D is diameter of D , and d_f is distance from center of D to the far zone. The non-uniform distribution of E_x - and E_y -components is explained by the different distribution of μ along x - and y -axes.

Combining the ratio of values M_m , one can create the distribution of μ corresponding to various requirements. For example, distribution of μ which is shown in Fig. 21, is obtained at the following values of particles in sub-domains Δ_m , $m = 1, 2, 3$: $M_1 = 11 \times 11 \times 4$, $M_2 = 9 \times 9 \times 3$, $M_3 = 7 \times 7 \times 4$. At such values of M_m , the values of the permeability are equal to 0.8745, 0.9026, 0.9451 in sub-domains Δ_1 , Δ_2 and Δ_3 , respectively. The amplitudes E_x and E_y of EM field for this case have more complicated structure because of the larger change of μ .

In Fig. 22, the piecewise-constant distribution of μ , created by prescribing the various values of function $h(x_m)$ in four sub-domains Δ_m , ($m = 1, 2, 3, 4$) of D , is shown. The number of particles in all sub-domains is equal to: $M = 11 \times 5 \times 5$, the values of $h(x_m)$ are the following $h_1 = 7i$, $h_2 = 9i$, $h_3 = 11i$, $h_4 = 13i$ (that is, $h(x_m)$ is piecewise-constant). The values of obtained μ and

Figure 16: Minimal values of σ_m components versus distance d between particles

respective values of wave number k are presented in Table 2. The minimal deviation of the obtained μ from the values μ_0 is observed in sub-domain Δ_1 and it is equal to 4%, this deviation reaches 7% in sub-domain Δ_4 . In order to increase the deviation of μ in certain sub-domain Δ_m it is necessary to increase the value of h_m in this sub-domain and keep the values of h_m in the rest of sub-domains the same.

Table 2. The properties of resulting domain D at piecewise-constant distribution of $h(x_m)$.

Subdomain	$h(x_m)$	μ	k
Δ_1	$-7i$	0.9616	0.0981
Δ_2	$-9i$	0.9512	0.0976
Δ_3	$-11i$	0.9410	0.0970
Δ_4	$-13i$	0.9310	0.0965

5 Conclusions

The numerical procedures for solving the EM wave scattering problem by one and many small impedance particles of an arbitrary shape are given. On this basis a method for creating the media with non-uniform distribution of magnetic permeability $\mu(x)$ is developed and tested numerically.

It is shown that the relative error of the asymptotic solution (17) compared with the Mie-type solution (52) in the paper [2] depends on the radius a of the

Figure 17: Maximal value of $\text{Div}\sigma_m$ versus number M of particles

particle, the distance r to the observation point, and on the parameter h which defines the surface impedance ζ of the particle.

The numerical results show that the assumptions $\text{Div}E_t = 0$ and $\text{Div}\sigma_m = 0$ on the surfaces of the particles are practically accurate: the relative error of these assumptions does not exceed 1.85% in the considered range of the parameters used for the solution of the scattering problem.

The computational results confirm the theoretical conclusion about the possibility to create media with piecewise-constant magnetic permeability μ . Creating such a μ is achieved either by embedding various numbers M_m of small particles in the sub-domains Δ_m of total domain D , or by changing the values $h(x_m)$ of the boundary impedances of the particles. Both approaches provide the possibility to change the initial values of μ in the range of 5% – 40%.
