The Cleft Palate-Craniofacial Journal

An Exploratory Study of Speech and Language Therapy Intervention for Children born with Cleft Palate ± Lip

| | |
|------------------|---|
| Journal: | <i>The Cleft Palate-Craniofacial Journal</i> |
| Manuscript ID | CPCJ-19-0445.R3 |
| Manuscript Type: | Original Article |
| Keywords: | Speech development, Speech perception, Speech production |
| Abstract: | <p>Children born with a cleft palate ± lip are at risk of developing speech and language difficulties, which may require intervention from a speech and language therapist (SLT). To date, there is no strong evidence to support one approach to intervention over another, neither is it clear which approaches or methods of provision are commonly used.</p> <p>Objectives: To describe the range of speech and language therapy interventions being used with children born with cleft palate in the UK up to 5 years of age. To explore the different ways interventions are being delivered.</p> <p>Design: A prospective study to conduct 9 semi-structured focus groups. Iterative content analysis was completed.</p> <p>Setting: Regional Cleft Lip and Palate Centers in the UK.</p> <p>Participants: 62 Speech and Language Therapy professionals from specialist cleft teams and community services.</p> <p>Results: Four main codes were identified: 'intervention approaches', 'service delivery models', 'decision making and rationale' and 'patient centered care'. Participants frequently discussed how they adopt an eclectic style when delivering intervention, the importance of an individualized approach for each child and service delivery constraints, such as a lack of resources.</p> <p>Conclusion: Insight into the multitude of intervention approaches used by SLTs, aspects which influence their decision making and the variability of service delivery models was gained. Uncertainty regarding which intervention approaches and methods for delivery are most effective provides rationale for future research, to improve the effectiveness of speech and language intervention for children with cleft palate ± lip.</p> |

Introduction

Children born with a cleft palate, with or without a cleft lip (CP±L), are at risk of developing speech, language and communication difficulties (Vallino-Napoli, 2011). Although a cleft palate is usually repaired during the first year of life, atypical speech patterns may prevail, with the potential for impact on intelligibility and consequences for a child's future social and educational progress (Richman et al., 2012).

Across the United Kingdom (UK), speech outcomes are audited at the age of five for children with CP±L. This is for the purpose of measuring the impact of interventions which have been provided at an individual and service level (Britton et al., 2014).

Analysis of this audit data has shown that 38.8% of the population do not achieve normal speech by age five (The Cleft Registry and Audit Network (CRANE), 2018).

What constitutes 'normal speech' is subjective and may vary from one person to another but work by Sell et al. (2015) provides more objective data and shows that for some children, their speech is severely affected. They reported that 17.2% of children born with CP±L are classified as 'only just intelligible to strangers' or 'impossible to understand' at five years of age. These figures are reflected in data which records need for speech and language therapy in this population. Evidence from the literature indicates that more than 50% of children born with CP±L require intervention from a Speech and Language Therapist (SLT) during childhood (Hardin-Jones and Jones, 2005; Peterson-Falzone, Hardin-Jones and Karnell, 2009), suggesting that problems with speech are often persistent and have significant impact for the child concerned.

1
2
3 Interventions delivered by SLTs may target a range of difficulties including speech
4 sound substitutions, comprehension and expression of language and social
5 communication skills. Improvement in speech, language and communication skills is
6
7
8 expected to impact positively on other aspects, such as the child's literacy skills,
9
10
11 confidence, participation and well-being (Bercow, 2018; Chapman, 2011;
12
13
14 McCormack et al., 2009).

15 16 17 18 *Speech and Language Therapy for Children with CP±L in the UK*

19
20
21 Children born with CP±L may have multiple speech, language and communication
22 needs, some of which could be unrelated to their cleft (Vallino-Napoli, 2011). The
23 interventions delivered by the SLT primarily focus on outcomes related to the child's
24
25
26 speech and language skills, for example articulating specific sounds, the expression
27
28
29 of ideas and information or the processing and understanding spoken words.

30
31
32 Children with CP±L who live in the UK and require speech and language therapy
33
34
35 intervention typically receive this from the government funded National Health
36
37
38 Service (NHS) though in recent years the availability and uptake of privatized,
39
40
41 independent speech and language therapy has become increasingly popular
42
43
44 (Bercow, 2008). Within the NHS both regional specialist services and community-
45
46
47 based services co-exist and often work in unity, although disparity regarding
48
49
50 provision is widely recognized (Bercow, 2018; Bercow, 2008). A report by the Lead
51
52
53 SLT Group and Chair of the Cleft Clinical Reference Group (Anonymous, 2016)
54
55
56 found inequity in care due to local and regional variations in how speech and
57
58
59 language therapy interventions for children with CP±L are funded and delivered,
60
61
62 following a survey of specialist SLTs across the UK. This group concluded that
63
64
65 speech and language therapy provision aligns with costs rather than evidence-based
66
67
68 practice or national recommendations. They raised concerns regarding reductions in

1
2
3 skills and expertise of cleft specialist SLTs due to down-grading of posts, which the
4
5 report considered would negatively impact upon the quality of intervention and
6
7 speech outcomes.
8
9

10 *Evidence for Speech and Language Therapy Interventions for Children with CP±L*

11
12 A systematic review of speech and language therapy interventions for children with
13
14 CP±L found little evidence to support any specific approach (Bessell et al., 2013).
15
16 Included in their analysis was a consideration of the different types of speech
17
18 impairment children might need intervention for. They summarized that cleft speech
19
20 difficulties can include both articulation and phonological disorders. An articulation
21
22 disorder is defined as an inability to produce specific speech sounds, whereas a
23
24 phonological disorder is characterized by pattern-based speech substitutions as a
25
26 result of cognitive-linguistic difficulties (McLeod and Baker, 2017). They suggested
27
28 that future intervention studies should investigate and compare approaches including
29
30 speech related motor techniques (aiming to elicit a sound by practising the physical
31
32 movement of the articulators) and linguistic techniques (targeting the child's
33
34 understanding and production of their rule-based sound system). The Bessell et al.
35
36 (2013) review highlighted the need for further methodologically rigorous studies to
37
38 inform the intervention evidence base for children with CP±L.
39
40
41
42
43
44

45 In addition to speech difficulties, children born with CP±L often have delayed
46
47 language development (Lancaster et al., 2020; Pamplona et al., 2015). In their
48
49 recent meta-analysis Lancaster et al. (2020) concluded that deficits in both
50
51 expressive and receptive language functioning are apparent in young children with
52
53 non-syndromic CP±L. However, language interventions for this population have
54
55 been under researched compared to speech interventions (Pamplona et al., 2015).
56
57 Pamplona et al. (2015) suggested this might be because speech disorders related to
58
59
60

1
2
3 velopharyngeal incompetence are most prominent when treating these children,
4
5 hence research has been driven by this clinical priority. Nevertheless a systematic
6
7 review of early language intervention for children with CP±L has been carried out
8
9 (Meinusch & Romonath, 2011). While the authors concluded that findings were
10
11 limited due to flaws in the design of the previous research, they acknowledged that
12
13 inclusion of the mothers in the therapeutic setting appeared to positively influence the
14
15 language abilities of children with CP±L, supporting the use of behavior training
16
17 programs for care-givers.
18
19
20

21 *Speech and Language Therapy Intervention in the Non-cleft Population*

22
23
24 Studies investigating intervention approaches used in speech and language therapy
25
26 in populations of children with non-cleft related speech and language needs have
27
28 highlighted some of the challenges that arise in carrying out such work (Roulstone et
29
30 al., 2012). These include variation in how interventions are described and labelled, a
31
32 mismatch between the evidence base and clinical practice and an awareness that
33
34 interventions are complex and typically consist of multiple elements.
35
36
37

38
39
40 It was hypothesized that this variability may impact upon the delivery of intervention,
41
42 as SLTs may alter specific named approaches from the way they were originally
43
44 conceived and delivered in trials or exploratory investigations. This may not be a
45
46 conscious action but nevertheless, the lack of consensus between SLTs in how
47
48 interventions are labelled and described may pose challenges when comparing
49
50 approaches. Similar patterns were observed in studies of intervention for children
51
52 with speech sound disorder (Baker et al., 2018) and with primary speech and
53
54 language impairment (Baker et al., 2018) and with primary speech and
55
56 language impairment (Roulstone et al., 2015).
57
58
59
60

1
2
3 Another challenge facing investigators is the presence of a lag between the
4 publication of research and its implementation in practice (Hegarty et al., 2018;
5
6 Olswang and Prelock, 2015). Hegarty et al (2018) in their survey of practitioners on
7
8 commonly used intervention approaches for children with phonological disorder
9
10 found evidence of a 'research-practice gap'. Specifically, they found that frequently
11
12 used interventions were not those which were identified as the most effective
13
14 according to the evidence in the literature. Hegarty et al.'s (2018) findings
15
16 highlighted the challenge clinicians face when implementing research findings into
17
18 practice. Olswang and Prelock (2015) discussed these challenges and introduced
19
20 implementation science principles, which advocate the application of research
21
22 findings to practice. These principles promote the researchers' awareness of real-
23
24 world settings, community engagement and consideration of behavior change
25
26 theories. Conducting research which is driven by clinicians' priorities, a bottom-up
27
28 approach, may positively influence the implementation of findings into everyday
29
30 practice.
31
32
33
34
35
36
37
38

39 The complexity of speech and language therapy interventions has been highlighted
40
41 as a challenge in both research and clinical practice. Further analysis of specific
42
43 intervention approaches has proposed that some techniques encompass multiple
44
45 elements (Baker et al., 2018). Baker et al. (2018) advocated establishing which
46
47 elements drive positive treatment effects and considered the complexities of
48
49 individual intervention approaches. The authors highlighted the importance of
50
51 collecting detailed information related to how intervention approaches are delivered
52
53 when conducting research.
54
55

56 57 *Delivery of Interventions* 58 59 60

1
2
3 While determining the critical components of an intervention approach is important,
4 variation in how individual SLTs deliver interventions must also be considered, given
5 the potential for additional impact on outcomes. Roulstone et al. (2015) in the 'Child
6 Talk' Study, a large-scale qualitative study of children with primary speech and
7 language impairment, investigated how interventions are delivered in terms of the
8 organization of services and individual SLTs' decision-making in the management of
9 the children's needs. Child Talk found that SLTs individualize therapy, often using
10 the phrase 'it depends' to illustrate how intervention management is influenced by
11 various factors (Roulstone et al., 2015; Morgan et al., 2019). Some of these factors
12 have been discussed in Furlong et al.'s (2018, pp.1135) paper; namely, "child factors
13 (e.g., age, severity of communication disorder), family factors (e.g., cultural
14 differences, engagement and attendance) and contextual factors (e.g., staffing
15 pressures, access to published programs)". 'Environmental factors' were also
16 discussed in Cronin et al.'s study (2020) which reported on interviews with Specialist
17 SLTs who work with toddlers with CP±L.

18
19 Comparisons of service delivery options have been addressed in the studies
20 described above (Roulstone et al., 2015; Morgan et al., 2019; Furlong et al., 2018).
21 Sugden et al.'s (2018) study of intervention intensity for the population of children
22 with non-cleft related speech sound disorder considered service delivery options.
23 They concluded that detailed reporting of intervention intensity is required in future
24 research to determine the optimal levels for effective treatment. Factors such as the
25 frequency, dosage, location, duration and person delivering the intervention are all
26 recognized to be crucial when investigating how intervention is delivered (Sugden et
27 al., 2018; Hegarty et al, 2018; Roulstone et al., 2012; 2015).

1
2
3 Consideration of the content of interventions and the manner of delivery are equally
4 relevant in the management of children with CP+/-L. To date, it has been mainly
5 gathered through the audit process described above. What has proved more
6 challenging however is how to gather robust data on the type of interventions,
7 dosage and manner of delivery that could be used alongside outcome data to
8 measure the impact of speech and language therapy intervention.
9
10
11
12
13
14
15
16
17

18 The aim of the present study was to understand expert opinions from clinicians, a
19 key component of the Evidence-Based Practice triangle (Sackett et al., 1996), in
20 order to complement the existing evidence base.
21
22

27 **Method**

28 *Ethics*

29
30 Ethical approval for this study was provided by Central Bristol NHS Ethics Committee
31 (IRAS Number: 135015).
32
33
34
35
36
37
38

39 *Design and Setting*

40
41 An iterative qualitative method (Srivastava and Hopwood, 2009; Berkowitz, 1997)
42 was used to obtain information about the types of interventions and patterns of
43 service delivery offered by speech and language therapy services for children born
44 with CP±L and to capture variations in service provision. The role of iteration, not as
45 a repetitive mechanical task but as a deeply reflexive process, is key to sparking
46 insight and developing meaning. Reflexive iteration is at the heart of visiting and
47 revisiting the data and connecting them with emerging insights, progressively leading
48 to refined focus of data collection and understanding.

60

Nine focus groups with speech and language therapy professionals were carried out in England and Wales. This approach, described by Robson (2002b), was selected following discussion with the cleft speech and language therapy teams as the best way to gather detailed information on the range and type of interventions being offered currently. Focus groups were scheduled at their regional cleft center site.

Participants

Sixty-two professionals participated in the focus groups: 43 cleft center specialist SLTs, 16 SLTs from community speech and language therapy services (eight with a specialism in cleft), three Speech and Language Therapy Assistants and one student SLT (Table 1). No participants dropped out of the current study. All cleft teams involved in recruiting to the Cleft Collective were invited to participate in the focus groups but not all were able to do so within the time available for data collection. During the focus groups only researchers and participants were present.

[INSERT TABLE 1 – Participants]

Procedure

Convenience sampling (Robson, 2002a) was used whereby invitations to participate in focus groups were emailed to the Lead SLTs at the regional Cleft Lip and Palate Services across the UK. A presentation about the study with eligible SLTs of a Cleft Speech Clinical Excellence Network meeting also drove recruitment. A team of five female researchers were involved in data collection, with research and clinical experience in the fields of speech and language therapy and psychology. Three of the researchers had PhDs and one worked part-time clinically as a Cleft Specialist SLT. All of the authors were involved in leading one or more focus groups.

1
2
3 Two researchers attended each focus group; one researcher acted as facilitator,
4 whilst the other supported facilitation and recorded field notes. The research was
5 undertaken from an ethnographic stance (Reed-Danahay, 2009; Ten Have, 2004),
6 with the aim to obtain scientific descriptions of SLTs' service cultures and practice
7 when working with the parents of and children with CP±L. Professional working
8 relationships were established between some researchers and participants prior to
9 the focus groups, as a result of previous involvement in research projects and clinical
10 liaison. The researchers' clinical and research roles were shared with participants
11 prior to the commencement of the focus groups.
12
13
14
15
16
17
18
19
20
21
22
23
24

25 Each focus group lasted two hours. Detailed notes were taken during each group, as
26 were audio-recordings using Olympus DS-2400 dictaphones. Technical difficulties
27 meant audio recordings were not captured during three of the groups and as a
28 consequence, quotes are not available from those sites. The focus groups took
29 place over a fifteen-month period to allow a realistic timescale for clinicians to be
30 freed from clinical commitments for attendance.
31
32
33
34
35
36
37
38
39

40 Researchers developed a topic guide, to encourage dialogue related to intervention
41 provision (Appendix 1). Participants were asked: 'which are the important aspects of
42 service delivery in speech and language therapy intervention for children with
43 CP±L?'. Once identified, the researcher probed further: 'which are the options
44 available for these service delivery choices?'. Intervention provision variations were
45 considered from both the specialist and community services. Following a semi-
46 structured format, questions were open ended, allowing participants to draw on their
47 experiences.
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Researchers initiated discussions about how intervention provision varies according
4 to age, between birth and five years. The participants defined age categories and
5
6 subsequently discussed how intervention provision varies for each age category in
7
8
9
10 turn.

11
12
13 Throughout the session the researchers probed for additional detail and clarification
14 e.g. 'could you describe it?' 'what do you mean by...?'. If required, the researchers
15
16 suggested examples of intervention options raised in previous focus groups to
17
18 stimulate discussions. The researchers checked their understanding of responses
19
20 from participants by repeating comments back to participants using alternative
21
22 vocabulary.
23
24
25
26
27

28
29 Once no new data were provided, the focus groups incorporated knowledge
30
31 elicitation activities (Shadbolt and Smart, 2015) to enable participants to reflect in
32
33 detail on their clinical practice and to make explicit the knowledge that they access in
34
35 certain clinical contexts. Clinicians have specialist expertise and knowledge, which
36
37 becomes second nature to them in daily practice and their rationale for decision
38
39 making can be difficult to articulate to non-specialist listeners. During knowledge
40
41 elicitation activities responses to stimulus questions were probed to ensure that clear
42
43 and unambiguous data were collected. Where specific terms or labels were used to
44
45 describe interventions, participants were asked to explain and elaborate on what they
46
47 meant by the term to ensure that there was consistency in how interventions were
48
49 described in the dataset. Examples of these activities are shown in Appendix 2.
50
51
52
53

54 55 *Analysis* 56 57 58 59 60

1
2
3 Qualitative analysis using iterative content analysis, as described by Elo & Kyngäs
4 (2008), enabled the researchers to form codes and sub-codes. Content analysis
5 uses a descriptive approach in both coding of the data and its interpretation of
6 quantitative counts of the codes (Downe-Wamboldt, 1992; Morgan, 1993,
7
8 Vaismoradi, Turunen & Bondas, 2013), supporting the use, interpretation and
9 integration of the data from the knowledge elicitation activities. This approach
10 provides an advantage over thematic analysis which is a purely qualitative, detailed,
11 and nuanced account of data (Braun & Clarke, 2006).

12
13
14
15
16
17
18
19
20
21
22
23 Transcripts from the audio recordings and field notes were read several times to
24 ensure the researcher (CW) was immersed in the depth and breadth of the content.
25
26
27 Transcripts were not returned to participants for corrections or comments. Codes
28 and sub-codes were discussed with all authors to check consensus of interpretation.
29
30
31
32 NVivo software version 10, (QSR International Pty Ltd, 2014) was used to support
33 the data analysis.
34
35
36
37

38 **Results**

39
40
41 Four codes were identified which covered what intervention is currently delivered and
42 how this is accomplished: 'intervention approaches', 'service delivery models',
43
44
45 'decision making and rationale' and 'patient centered care'. Each code was
46 populated with four sub-codes (Table 2).
47
48
49
50

51 *[INSERT TABLE 2 – Codes and Sub-codes]*
52
53

54
55 Each of the codes are described in sequence below, together with examples of data
56 which were used to identify the codes. Where relevant and to aid interpretation of
57
58
59
60

1
2
3 the findings references to the existing literature are included within the results
4
5 section.
6
7

8 9 **Intervention Approaches**

10 11 *Therapeutic techniques*

12
13
14 Participants discussed which therapeutic techniques they use with children with
15 CP±L between birth and five years. They categorized the type of intervention
16
17 provided into two broad categories: direct intervention and indirect intervention.
18
19 Direct intervention is delivered by the SLT whereas indirect intervention is often
20
21 consultative, guided by the SLT but delivered by another person, such as school staff
22
23 or a Speech and Language Therapy Assistant.
24
25
26
27

28
29 *'We always do indirect therapy whatever we do' (FG 2)*
30
31

32
33 Forty-nine direct intervention approaches were listed in total, with some specific
34
35 approaches reported to be in frequent use with this population. Participants reported
36
37 which approaches they would use with children in different age categories, which
38
39 they defined; the common age boundaries reported by seven out of nine focus
40
41 groups were, 0-18 months, 18 months-3 years and 3-5 years (Table 3). Participants
42
43 mentioned using technology, such as apps on iPads, to support their interventions.
44
45
46
47

48 *[INSERT TABLE 3 – Intervention Approaches]*
49
50

51
52 The practice of many SLTs was characterized by an eclectic approach, which
53
54 incorporates aspects of a few different intervention approaches rather than rigidly
55
56 following one approach as it has been originally described. These findings are
57
58
59
60

1
2
3 comparable to the non-cleft population (Baker et al., 2018; Hegarty et al., 2018) and
4
5 evidence suggests most SLTs use an eclectic approach to intervention.
6
7

8
9 *'That eclectic approach, we all do it' (FG 4)*
10

11
12 *'We don't tend to use a set, specific programme' (FG 6)*
13
14

15 Participants recognized that activities they conduct, or ask communication partners
16
17 to complete, often target multiple areas of development simultaneously. This
18
19 approach was felt to allow for greater flexibility for the SLT to draw upon their
20
21 experiences and promptly respond to the child's performance. SLTs commented that
22
23 this enabled an individualized approach, targeting specific areas of need.
24
25

26
27
28 This eclectic approach recognizes that children with CP±L can experience various
29
30 speech and language difficulties and participants are motivated to deliver patient-
31
32 centered care.
33
34

35 36 *Variability* 37

38
39 Participants were aware of similarities and differences in the range of interventions
40
41 provided by their service, making comparisons between community speech and
42
43 language therapy services and regional cleft centers.
44
45

46
47 *'That's not dissimilar to other teams' (FG 7)*
48
49

50
51 Variability between individual SLTs regarding the selection of intervention
52
53 approaches and their delivery was reported. Despite some participants raising
54
55 concerns about whether they were carrying out interventions accurately, they also
56
57 commented that variation is acceptable as it reflects the broad, variable nature of
58
59 speech and language therapy interventions.
60

1
2
3 *'Every therapist will be different from another therapist and then every child will have a*
4 *different need and require different tools on the whole' (FG 4)*
5
6
7

8 Previous research has highlighted that variability in which interventions are provided
9
10 is usual for this population. For example, Bessell et al., (2013) reported both
11
12 articulation and phonology therapeutic interventions in their systematic review.
13
14
15

16 *Terminology*

17
18
19

20 As participants discussed how interventions varied, they were mindful of their use of
21
22 terminology and how SLTs may describe the same techniques or processes, but use
23
24 different labels. These terminology variations were observed between and within
25
26 focus groups, suggesting that SLTs within teams may vary in their use of terminology
27
28 as well as those across teams.
29
30
31

32 *'I'm just concerned that one person's indirect is another person's direct' (FG 2)*
33
34
35

36 *The Evidence Base*

37
38
39

40 When discussing intervention approaches participants did not routinely mention the
41
42 evidence base. Some comments suggested SLTs feel that replicating methods from
43
44 intervention research papers does not always work in their clinical practice.
45
46

47 *'Nobody follows one approach, no, ever ever, not unless you are doing a research project'*
48
49 *(FG 5)*
50
51

52 Participants often felt the recommended methods were too rigid to be implemented in
53
54 their service. SLTs highlighted a lack of evidence related to intervention provision for
55
56 children with CP±L.
57
58
59
60

1
2
3 *'Where is the evidence base that says putting them on review for 3 - 6 months allows them*
4 *to consolidate (FG 1)'*
5
6
7

8 The use of non evidenced based approaches identified by Bessell et al. (2013) were
9 observed in this study. For example, it was reported that Multisensory Input-
10 Modelling (\pm Output) (Harding and Bryan, 2002) is delivered frequently between birth
11 and three years of age, despite a limited evidence base for its effectiveness.
12
13
14
15
16

17 Participants in the current study reported the effectiveness of this intervention, from
18 clinical-level evidence, such as the child using more oral consonant sounds following
19 intervention. It should be noted that the improvements observed by participants is
20 anecdotal evidence and could be the result of enhanced language development and
21 natural maturation.
22
23
24
25
26
27
28
29

30 **Service Delivery Models**

31 *Frequency*

32
33
34
35
36 Frequency denotes how often speech and language therapy intervention is provided.
37
38 Kaipa and Peterson (2016) used the term 'dose frequency' similarly, to describe the
39 number of times intervention sessions are delivered per unit of time, for example
40 twice a week or twice a month. Participants mostly interpreted frequency in relation
41 to direct intervention rather than indirect intervention. Variation was reported
42 between services (Figure 1), for reasons such as the child's needs and availability of
43 resources.
44
45
46
47
48
49
50
51

52
53 *'They have therapy for as long as they need it because they might be alternating between us*
54 *and the community' (FG 3 – regional cleft team)*
55
56
57
58
59
60

1
2
3 An explanation for the variability was that some participants from regional cleft
4 centers felt they were able to offer intervention more frequently than community
5 speech and language therapy services. Participants spoke positively about specialist
6 speech disorder teams in the community services, who were sometimes able to offer
7 more frequent intervention if required. Variation was also reported as a result of
8 factors related to the child's family and environment.
9

10
11
12
13
14
15
16
17
18 *'As they become more engaged and more able you might increase the frequency' (FG 2)*
19

20
21 *[INSERT FIGURE 1 - Service Delivery Models]*
22

23 *Duration*

24
25
26
27
28 Duration refers to the length of time an intervention session lasts, defined by Kaipa et
29 al. (2016, p.508) as "the total time period during which the intervention is provided".
30
31 Depending on the intervention targets the session length varied, however the
32 average duration for an individual therapy session was agreed to be between 30-45
33 minutes (Figure 1). Participants described adapting the duration of sessions
34 depending on the individual child and commented that they worked flexibly.
35
36
37
38
39
40
41
42

43 *'Even with the really compliant children, when you try and go over the half hour, you notice*
44 *that the accuracy of their productions just tail off' (FG 3)*
45

46
47
48 *'When you are working with them and getting used to the session you might do longer and*
49 *longer with them' (FG 5)*
50

51 *Location*

52
53
54
55
56
57
58
59
60

1
2
3 The location in which intervention was provided is widely variable (Figure 1). It was
4 reported that numerous aspects influence this, such as service protocols and the
5 presenting needs of the child and family.
6
7
8
9

10
11 *'There are some really interesting things that you miss if you don't get the opportunity to do a*
12 *home visit' (FG 1)*
13
14

15
16 *'Everything is done in centre, we don't do outreach at all' (FG 7)*
17
18

19 20 *Person to Deliver Intervention*

21
22
23 Participants listed a variety of people who would deliver intervention to children with
24 CP±L (Figure 1), although they did not define whether each person was perceived to
25 be a direct or indirect contact. The SLTs reported that the person with a duty of care
26 for a child decides who will deliver the intervention, based on service protocols,
27 intervention targets and factors such as the geographical location, support networks
28 and whether the child attends an educational setting.
29
30
31
32
33
34
35

36
37
38 The importance of involving communication partners, such as parents/carers and
39 school or nursery staff in intervention delivery was discussed, raising questions
40 regarding whose responsibility it was to consistently deliver intervention for a child
41 with CP±L.
42
43
44
45
46
47

48 *'You get the parents and be like oh can you have a go now and that's what I want you to do*
49 *at home, give them things for homework' (FG 2)*
50
51
52

53 54 **Decision Making and Rationale**

55 56 *Resource Constraints and Barriers*

57
58
59
60

1
2
3 A shortage of resources, finances, staffing, equipment and overstretched services
4 were issues that were repeatedly raised in all focus groups. These shortfalls were
5 reported to impact negatively on intervention provision.
6
7
8
9

10
11 *'We'll be doing more than community therapists because they have just got longer wait*
12 *times' (FG 3)*
13
14

15
16 Participants gave examples of ways that financial cutbacks have impacted on their
17 choice of intervention approaches and affected decisions about the frequency or
18 person to deliver the intervention.
19
20
21
22

23
24
25 *'I don't have the equipment anymore to be able to tape, video and make it into a DVD' (FG 1)*
26
27

28 Best practice regarding intervention provision was reported to be based on clinical
29 judgment, prioritizing the child's needs. Participants described service constraints
30 being a barrier to decision making and to children receiving appropriate and effective
31 interventions with some services providing intervention based on cost rather than
32 clinical judgments, confirming findings from Bercow: Ten Years On (2018).
33
34
35
36
37
38
39

40
41 *'It would be capped, you can only see this child once, some areas there is no therapy, that's*
42 *what happens' (FG 4)*
43
44

45 46 *Regional and Geographical Considerations*

47

48
49 The phrase 'postcode lottery' is well known in UK healthcare; participants described
50 how children with CP±L may be disadvantaged in terms of the frequency of
51 intervention as a result of where they live.
52
53
54

55
56
57 *'Depending on where the children live, there isn't always a cleft specialist there' (FG 1)*
58
59
60

1
2
3 These inequalities in intervention provision exist nationally and remain unchanged
4 since the report by the Lead SLT Group and Chair of the Cleft Clinical Reference
5
6 Group (Anonymous, 2016).
7
8
9

10
11 Living further from a regional cleft center was reported to reduce access to
12
13 intervention in some areas, with SLTs commenting they would be less likely to offer
14
15 frequent direct intervention if they had to travel a substantial distance to deliver
16
17 intervention for a child.
18
19

20
21
22 *'If some children can't come to me, I can't offer weekly therapy because it would be just too*
23
24 *much of my time spent travelling' (FG 1)*
25

26
27 This issue was not reported by all participants and it seems that some geographical
28
29 areas of England and Wales and specialist services are better resourced. Moreover,
30
31 it appears that geographical location is not always a barrier to intervention provision if
32
33 the child's parent/carer is able and willing to travel to access intervention. It was
34
35 recognized that the time spent travelling to intervention sessions may impact on the
36
37 child's school attendance and attainment.
38
39

40 41 42 *Family Circumstances* 43

44
45 Many participants considered the wider needs of the child's family as vital when
46
47 delivering intervention.
48
49

50
51 *'I do try and accommodate the parents as much as possible with regards to day and time'*
52
53 *(FG 3)'*
54

55
56 A shared understanding with communication partners of the child's targets and
57
58 rationales for interventions were deemed crucial to intervention success. Family
59
60

1
2
3 dynamics and associated responsibilities, for example childcare for siblings was
4 described as necessary to consider when planning intervention.
5
6

7
8
9 *Siblings, looking after their children, school drop off, that kind of stuff is often a barrier to*
10 *coming, chaotic families with lots going on' (FG 1)*
11
12

13 *Role of Cleft Specialist as Coordinator*

14
15
16
17 Intervention for children with CP±L is provided by regional cleft centers, community
18 speech and language therapy services and independent SLTs. Participants
19 explained that when making decisions regarding intervention for this population it is
20 crucial to liaise and collaborate with other services to ensure that care is cohesive.
21
22

23
24
25
26
27
28 *'Our priority is to get them having effective therapy and we get whoever we can, wherever*
29 *they are to deliver that' (FG 3)*
30
31

32
33
34 SLTs from regional cleft centers voiced that their role involved supporting generalist
35 SLTs, when setting targets and selecting intervention approaches.
36
37

38
39 *'Helping set targets and monitor so you are supporting' (FG 2)*
40
41

42
43 Likewise, community SLTs and Speech and Language Therapy Assistants
44 commented that they receive supervisory support from the cleft specialist SLTs.
45
46

47 **Patient Centered Care**

48 *Child's Presentation*

49
50
51
52 Intervention delivery options and selection of approaches are informed by the child's
53 progress and their developmental level. Participants highlighted the importance of
54
55
56
57
58
59
60

1
2
3 conducting a thorough assessment prior to the commencement of intervention, in
4
5 order to ensure appropriate targets are set.
6
7

8
9 *'Would depend on what they were working on and how they coping with it' (FG 1)*
10

11
12 If a child presents with a specific medical or genetic diagnosis, impacting on their
13
14 cognitive skills and functioning, it was reported to impact upon the intervention they
15
16 received. Participants discussed that in certain geographical locations, intervention
17
18 is only offered to those with a recognized Education, Health and Care Plan (Sales
19
20 and Vincent, 2018), i.e., a legal document provided by UK local government
21
22 agencies which specifies the provision and intervention required to support the
23
24 child's development. Participants talked about taking a holistic approach when
25
26 considering intervention provision, considering the whole child and how factors such
27
28 as attention and listening skills or the child's cognitive ability may impact upon
29
30 progress in therapy sessions.
31
32
33
34
35

36
37 *'The priority when you first meet that cleft child, the cleft like characteristics or is it the*
38
39 *attention levels, the language levels and which comes first and when are all kind of key' (FG*
40
41 *1)*
42
43

44
45 Despite concerns being raised regarding a lack of resources and feeling constrained
46
47 by specific care pathways, the importance of an individualized approach for each
48
49 child was frequently stated as a critical factor. Participants spoke about putting the
50
51 child at the heart of their decision-making regarding intervention.
52
53

54
55 *'It's all about the individual basically' (FG 2)*
56
57

58
59 Similarly, Baker et al (2018) reported that SLTs purposefully provide a wide variety of
60
service delivery options, adapting interventions to suit each individual's needs.

1
2
3 Participants in this study illustrated how they work holistically and suggested that
4 children with CP±L can present with complexities due to the multidisciplinary nature
5 of their care. Aspects such as the child's hearing status and presence of complex
6 medical needs were reported to be important to consider when planning intervention.
7
8 Despite decisions surrounding intervention provision being managed by the SLT,
9
10 participants voiced their aspirations to work collaboratively with the child and family,
11
12 discovering their opinions and wishes for intervention too.
13
14
15
16
17
18
19

20 *Timing of Input*

21
22
23 An awareness of the child's cleft care treatment pathway affects how intervention is
24 delivered, ensuring that the timing and type of intervention is appropriate. SLTs
25 reported timing of surgeries, multidisciplinary care and the child's psychological
26 adjustment as factors they include in their decision-making.
27
28
29
30
31
32

33
34 *'What's happening with them in terms of their cleft care as a whole, other interventions,*
35 *surgeries...how they are coping with the diagnosis and any other health issues' (FG 1)*
36
37

38
39 When assessing whether a child would benefit from speech and language therapy
40 intervention, participants identified that it was important to address the child's
41 readiness. Intrinsic factors such as the child's motivation were considered alongside
42 other priorities, such as education and extracurricular activities.
43
44
45
46
47
48

49
50 *'Depending on the child's motivation, the parent's commitment, progress in therapy...it's all*
51 *those areas we take on board' (FG 3)*
52
53

54 *Supporting Factors*

55
56
57
58
59
60

1
2
3 Participants suggested that speech and language therapy intervention provision is
4 more effective when support and carry over work is completed by other agencies and
5 family members. Participants described their role in ensuring support networks were
6 established for the child when receiving intervention and the challenges that present
7 when a support network breaks down.
8
9

10
11
12 Flexibility in service delivery models was reported to be beneficial for intervention
13 provision. SLTs from specialist services or regional cleft centers described an ability
14 to work with greater flexibility and more resources (time, staffing, equipment) when
15 compared to community services, however this was not the case for all.
16
17

18
19
20
21
22
23
24
25
26
27 *'That's the luxury of our service is that we can be very bespoke...not one size fits all' (FG 2)*

28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
'We see them when they are coming in for another appointment to reduce the burden' (FG 4)

But where available the SLTs noted that this flexibility supports patient centered care and intervention provision based on clinical judgment rather than rigidity due to service constraints. These findings are consistent with those of Furlong et al. (2018), who reported that the location of sessions, family engagement and attendance were all important in ensuring patient centered care.

Age and Expectations

Although some speech and language therapy services have care pathways for children at specified ages, SLTs mentioned how they create packages of intervention taking into account the child's developmental stage and cognitive abilities, not just their chronological age.

'It's not actually about the age it's about their developmental stage' (FG 1)

1
2
3 They reported this as necessary to ensure that children access appropriate
4
5 intervention for their needs. For most children without significant developmental
6
7 delay however, participants were able to classify intervention approaches broadly
8
9 into age categories (Table 3).
10
11
12
13

14 Discussion

15
16
17 This study aimed to investigate what intervention is currently provided by SLTs for
18
19 children born with CP±L until the age of five and how it is delivered. Nine focus
20
21 groups were carried out and subsequent iterative content analysis identified four
22
23 main codes with corresponding sub-codes.
24
25
26

27 This study revealed that a wide range of intervention approaches are used by SLTs
28
29 with this population and that variability exists in service delivery models. The
30
31 variability described may be explained by the lack of evidence for speech and
32
33 language interventions, leading to uncertainty for SLTs. Focus group participants
34
35 were able to share examples of factors which they believed impacted positively on
36
37 intervention provision, whilst acknowledging issues and constraints faced. It was
38
39 clear from the content analysis that, while discrete codes and sub-codes could be
40
41 identified, these were not independent of each other but rather were closely
42
43 interconnected, as discussed below.
44
45
46
47
48

49 *Intervention Approaches and Service Delivery Models*

50
51
52 Inconsistencies regarding the use of terminology have been reported in previous
53
54 studies (Baker et al., 2018; Roulstone, 2012). Inconsistent terminology, in particular
55
56 the use of one label for more than one type of intervention or multiple labels for a
57
58 single intervention, can be problematic in research and clinical practice. Without a
59
60

1
2
3 full appreciation of the degree of variation in terminology, there is the potential for
4
5 confusion and a misplaced belief that practice is evidence based.
6
7

8
9 Participants reported using direct and indirect intervention with children with CP±L.

10
11 Indirect intervention may often be offered due to resource shortages, limited
12
13 availability for direct intervention provision and to support consolidation of skills after
14
15 direct intervention sessions. Indirect intervention was valued equally to direct
16
17 intervention by most participants in the current study. Sugden et al.'s (2018) study
18
19 found the most common person to deliver individual intervention, in the speech
20
21 sound disorder population, is an SLT. However, in present work participants named
22
23 a range of people who deliver intervention, including the SLT. School staff and
24
25 caregivers were reported to deliver indirect intervention for children born with CP±L,
26
27 under the supervision of an SLT. Indirect interventions were sometimes provided in
28
29 addition to direct intervention from the SLT. Sugden et al.'s study (2018) focused on
30
31 both direct and indirect intervention provision in Australia, which may explain the
32
33 variance in findings when compared to the current study.
34
35
36
37
38
39

40 Participants described a multitude of service delivery options and reported that as
41
42 clinicians they often work flexibly. This is advantageous when delivering intervention
43
44 in a climate with stretched resources, striving to meet the needs of the individual,
45
46 whilst balancing service-level restrictions.
47
48
49

50 In the present study, the authors followed the advice of Baker et al. (2018) who
51
52 advocated for the use of explorative methodologies when investigating speech and
53
54 language therapy interventions. Participants listed intervention approaches delivered
55
56 at specified ages and it is noted that there is a high level of overlap between the age
57
58 categories, for example, diagnostic therapy and articulation therapy were in common
59
60

1
2
3 use with all children up to five years of age. The notion that intervention is delivered
4 in an eclectic style has been identified in previous literature (Baker et al., 2018;
5
6 Hegarty et al., 2018) and participants described how they rarely use one approach in
7
8 isolation, favoring the use of multiple approaches concurrently to achieve a specific
9
10 goal.
11
12
13

14
15
16 Meinusch & Romonath's (2011) systematic review of early language interventions for
17
18 children with CP±L concluded that the involvement of caregivers in the therapeutic
19
20 setting enhanced the child's language abilities. Participants in this study provided
21
22 examples of liaison with caregivers, providing them with advice and therapeutic
23
24 activities to support the child's development in the home environment. In addition to
25
26 positive intervention treatment effects from other studies (Ha, 2015; Dobbelsteyn et
27
28 al., 2014) this demonstrates successful implementation of research findings into
29
30 clinical practice.
31
32
33

34
35
36 Previous research has investigated intervention factors such as the frequency,
37
38 dosage, location, duration and the person to deliver intervention, which are
39
40 recognized to be important when studying how intervention is delivered (Hegarty et
41
42 al, 2018; Roulstone et al., 2015; Roulstone et al., 2012). Participants described a
43
44 multitude of intervention factors, which reflect resource availability and consideration
45
46 of the individual needs of the child and their family.
47
48

49 *Decision Making and Rationale*

50
51

52
53 The current study found that intervention provision was variable between individual
54
55 SLTs and across services. Roulstone et al. (2015) reported similar findings in 'Child
56
57 Talk' and both studies highlight that participants use the phrase 'it depends' when
58
59 discussing intervention. This illustrates how multifactorial intervention management
60

1
2
3 is and the factors SLTs consider when delivering intervention. The work by Furlong
4 et al. (2018) supports this by categorizing factors as 'child factors', 'family factors'
5 and 'contextual factors'. The present study identified a number of additional factors
6 which need to be considered for children with CP+/-L including timing of surgery,
7 comorbidities such as hearing loss and syndromic status and location of the
8 intervention provision.
9
10
11
12
13
14
15
16
17

18 *Patient Centered Care*

19
20
21 Factors that were felt to influence decision-making regarding intervention were;
22 service level constraints, the needs of the child and family and previous clinical
23 experience, comparable to Furlong et al.'s (2018) findings. The current study
24 reported geographical challenges as a factor, for participants working in the regional
25 cleft centers, a finding that was not identified in Furlong et al.'s (2018) study. Cronin
26 et al. (2020) reported 'physical geography/population density' was an important
27 consideration for speech-language pathology practice when working with children
28 with CP±L.

39
40

41 In the current study, participants from regional cleft centers described their role in the
42 multidisciplinary team and how they incorporate supporting the child and family
43 through their cleft treatment journey into their intervention provision. This was
44 viewed as an additional aspect of intervention provision when compared to local
45 speech and language therapy services and the non-cleft population. This
46 multidisciplinary role demonstrates how intervention is delivered in a holistic manner
47 and contributes to wider public health care, endorsed by Public Health England
48 (Hindle and Charlsworth, 2019).

59

60 *Limitations*

1
2
3 The present study has some limitations which should be acknowledged. This study
4 aimed to investigate intervention provision across the UK, however participation from
5
6 Scottish and Irish sites was not possible within the time available and findings may
7
8 not therefore accurately reflect service provision in these geographical locations.
9
10

11
12
13 It is recognized that there was less participation representing community speech and
14
15 language therapy services in this study, therefore findings could be biased towards
16
17 specialist service intervention provision.
18
19

20
21
22 A further limitation of this study is that transcripts were not checked by participants
23
24 for misinterpretations following the focus groups. Additionally, the researchers' prior
25
26 clinical experience and existing relationships with participants may have influenced
27
28 the data, as participants may have experienced acquiescence bias, responding
29
30 positively in order to please the researchers (Winkler et al, 1982).
31
32

33 34 *Clinical Implications* 35

36
37
38 The aim of this study was to undertake exploratory work to understand interventions
39
40 currently provided in clinical practice and usual patterns of dosage and delivery for
41
42 children born with CP±L up to 5 years of age across the UK. The findings from this
43
44 work do not yet assist us in providing evidence to support interventions for children
45
46 with CP±L. New knowledge which can be used to inform clinical practice has
47
48 nevertheless already been generated by this work and has informed the
49
50 development of a survey of intervention received by participants in the Cleft
51
52 Collective Cohort Study (Wren et al., 2018). The Cleft Collective Cohort Study is a
53
54 large prospective clinical cohort study of children born with CP±/L, investigating
55
56 causes of cleft, the best treatments and the impact of cleft on those affected and their
57
58
59
60

1
2
3 families (<http://www.bristol.ac.uk/cleft-collective/professionals/access/>). Survey
4
5 responses will be available for clinicians and academics to combine with other data
6
7 collected by the study, for example speech outcome data, to address clinically
8
9 meaningful questions regarding the impact of SLT intervention.
10
11

12
13 We now have a clear picture of the range of interventions being used by SLTs in
14
15 England and Wales for this population. We know at what ages each is being used
16
17 and we have an understanding of the factors which affect clinical decision making
18
19 and choice of intervention. This repertoire of interventions will aid clinicians who are
20
21 new to the field in their management and will provide a qualitative benchmark for
22
23 services to compare themselves to.
24
25

26
27
28 This study's objective to understand expert opinions from clinicians, a key
29
30 component of the Evidence-Based Practice triangle (Sackett et al., 1996),
31
32 complements the existing evidence base. Discussion from participants in this study
33
34 regarding the challenges they face implementing research findings into practice,
35
36 aligns with previous findings from Hegarty et al. (2018). It is therefore important for
37
38 future studies to adhere to implementation science principles (Olswang and Prelock,
39
40 2015), thus increasing the likelihood of research findings being incorporated into
41
42 everyday practice. Inconsistencies related to terminology are important to consider
43
44 in future research studies, to ensure a deep understanding of the nature and content
45
46 of intervention approaches used in speech and language therapy practice.
47
48
49
50

51 52 **Conclusion** 53 54

55
56 The present study has identified a large number of speech and language therapy
57
58 interventions which are being delivered to children born with CP±L across the
59
60

1
2
3 England and Wales. Exploration of service delivery models and the aspects which
4 influence SLTs' decision making, with regards to intervention provision have
5 illustrated both similarities and differences nationally. Many of the intervention
6 approaches discussed in this study were not in the Bessell et al. (2013) review, either
7 because they did not fulfil the eligibility criteria suggesting the evidence is low level,
8 or because they had not been reported in the literature at the time of the review.
9 Current evidence for the latter remains at low level however, limited mostly to single
10 case or small group studies.
11
12
13
14
15
16
17
18
19
20
21
22

23 This study recognizes the uncertainty as to which interventions are effective for this
24 population and which methods of delivery are the most appropriate. Determining
25 which interventions and patterns of delivery are most commonly used within this
26 population will help identify which are the most salient interventions to investigate in
27 efficacy studies and in turn have the potential for immediate impact on practice.
28

Appendix 1: Topic Guide for Focus Groups

- Consent to be obtained for participation
- Introduce the research project

- What are the important domains of interest in speech and language therapy (SLT) intervention for cleft?

- What are the options available for each domain (identified in previous point) in:
 - the central cleft service?
 - the local community SLT services within the region?
 - independent SLT services?

- How does this differ for various age ranges between 0-5 years of age?

- How might this information be represented in questions in a survey?

Probes:

- Encouraging participants to expand on a point they have raised.
- Asking for clarification from participants.
- Defining terms such as 'domains of interest' for the participants.
- Repeating back and summarising the information provided in order to stimulate further discussion.

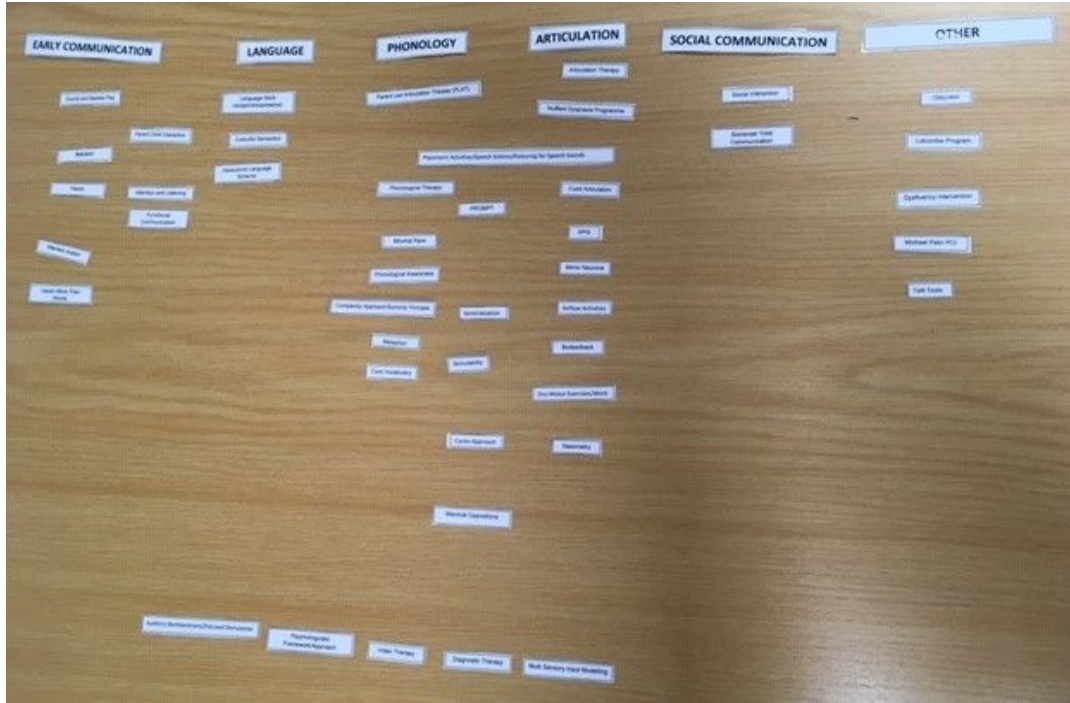

Appendix 2: Knowledge Elicitation Activities

Activity 1 - Classification of Intervention Approaches:

The aim of this activity was to discover whether intervention approaches could be classified into specific categories.

Discussion from previous focus groups highlighted variation across participants, and sites and their individual opinions regarding this matter.

1. Focus group participants were divided into sub-groups of 2-3 people whilst sat at a table.
2. Participants were provided with 6 cards: 'Early Communication', 'Language', 'Articulation', 'Phonology', 'Social Communication' and 'Other'.
3. Participants were instructed to lay the cards horizontally on the table and use these as the category headings.
4. A further 46 cards with the name of an intervention approach on were provided to each group. The intervention approaches were reported from previous focus groups to be in use with children with CP±L until 5 years of age.
5. Participants were given approximately 15 minutes to place the intervention approach cards under the corresponding categories. If participants were unable to assign a card to a category they were prompted that they could leave it to one side or place it in between 2 or more categories.
6. The discussions between the participants whilst completing the activity were audio recorded and the researchers made notes regarding the participant's decision making and interesting points raised.
7. After the sub-groups had completed the activity the focus group facilitator asked the participants to describe how they found the task, any difficulties they experienced, and if they felt anything was missing.
8. Comparison between the group's classification of approaches stimulated further discussion.
9. Photos were taken of the cards at the end of the activity for further analysis.

Primary Aim for Episode of Care:

To enable child to use some oral residue consistently e.g. b, f.

Approach/Method

- 1 MSIM
- 2 Air/low resistance
- 3 Moving on to phonological therapy
- other:
Cued articulation program

Specific Programmes Used

- 1 MSIM
- 2
- 3
- other:

Training/Advice Given

- 1 Demonstration to parent/local SLT
- 2 Discussion of explanation to parent/local SLT of selected steps
- 3 Modelling & explanation to child
- other:

Resources and Homework

- 1 MSIM videos on YouTube & lyrics
- 2 Spelling sound target advice & resources
- 3
- other:

Who was the agent of change?

?? Close SLT

Who was the facilitator?

Mum, local SLT, school class

Age of child 4;10 - 5;1 yrs

Activity 2 - Delivery of Intervention

To support the development of an intervention tool (online data collection tool) for use in the Cleft Collective Speech and Language Study the researchers wanted to explore the use of terminology related to the domains of intervention.

- 1
2
3
4
5 1. Individual participants were provided with an A4 sheet of paper with
6 predetermined fields:
7
 - 8 - Primary Aim for Episode of Care
 - 9 - Age of Child
 - 10 - Agent of Change
 - 11 - Facilitator
 - 12 - Approach/Method
 - 13 - Resources and Homework
 - 14 - Specific Programmes used
 - 15 - Training/Advice given
- 16
17 2. They were asked to complete the fields whilst thinking about a child they have
18 provided intervention for. They were given approximately 10 minutes.
- 19
20 3. After they had completed the sheet the focus group facilitator stimulated
21 discussion about the ease of the task.
- 22
23 4. When participants highlighted terms that they found challenging to
24 comprehend the focus group facilitator prompted by asking about their
25 interpretation and encouraged other participants to compare their opinions.
26 This was audio recorded for later analysis.
- 27
28 5. The sheets were collected by the focus group facilitator at the end of the
29 activity and were used for analysis.
