20 **Abstract**

21 China is seeking to unlock its shale gas in order to curb its notorious urban air  
22 pollution, but robust assessment of the impact on PM<sub>2.5</sub> pollution of replacing coal  
23 with natural gas for winter heating is lacking. Here, using a whole-city heating energy  
24 shift opportunity offered by substantial reductions in coal combustion during the  
25 heating periods in Urumqi, northwest China, we conducted a four-year study to reveal  
26 the impact of replacing coal with natural gas on the mass concentrations and chemical  
27 components of PM<sub>2.5</sub>. We found a significant decline in PM<sub>2.5</sub>, major soluble ions and  
28 metal elements in PM<sub>2.5</sub> in January of 2013 and 2014 compared with the same periods  
29 in 2012 and 2011, reflecting the positive effects on air quality of using natural gas as a  
30 whole-city heating fuel. This occurred following complete replacement with natural  
31 gas for heating energy in October 2012. The weather conditions during winter did not  
32 show any significant variation over the four years of the study. Our results reveal that  
33 China and other developing nations will benefit greatly from a change in energy  
34 source, i.e., increasing the contribution of either natural gas or shale gas to total  
35 energy consumption with a concomitant reduction in coal consumption.

36 **Introduction**

37 Concerns about the effects of atmospheric particulate matter (hereafter referred to as  
38 PM) range from their influence on biogeochemical processes<sup>1,2</sup> and climate change<sup>3,</sup>  
39 <sup>4</sup> to public health.<sup>5,6</sup> Recent interest in China has focused on PM<sub>2.5</sub> (fine particles; PM  
40 with aerodynamic diameter  $\leq 2.5 \mu\text{m}$ ) because numerous studies have provided  
41 convincing evidence of an association between ambient PM<sub>2.5</sub> and regional haze<sup>7-9</sup> as  
42 well as human mortality/morbidity.<sup>10-12</sup>

43 Existing field observations in China reveal that PM<sub>2.5</sub> levels in urban sites show a  
44 distinct seasonal pattern, with much higher mass concentrations in winter than in

45 summer.<sup>13-15</sup> This is particularly true in northern China where coal-based heating  
46 systems in winter have become the dominant sources of SO<sub>2</sub>, NO<sub>x</sub> and primary PM.  
47 According to Chen et al.,<sup>16</sup> extended-use heating systems that substantially intensify  
48 total suspended particulate (TSP) pollution have resulted in an average loss of more  
49 than five years of life expectancy for the 500 million residents of the northern China.  
50 Moreover, Meng et al.<sup>11</sup> have explored the association between size-fractionated  
51 particle number concentrations and daily mortality in Shenyang (capital city of  
52 Liaoning province, northeast (NE) China) and conclude that adverse health effects  
53 may increase with decreasing particle size. In Xi'an (capital city of Shaanxi province,  
54 northwest (NW) China) Huang et al.<sup>10</sup> observed a greater risk from PM<sub>2.5</sub> and selected  
55 species on all causes of mortality during periods of heating from 2004 to 2008.  
56 Although coal can be expected to continue playing a vital role as an abundant and  
57 economic energy source in the foreseeable future, these studies clearly indicate that a  
58 strategy of switching away from coal to other energy sources for heating in China is  
59 urgently needed.

60 The environmental benefits of replacing coal with other energy sources (e.g.,  
61 biofuels, wind, hydro, solar, and nuclear power) are well established in various  
62 scenarios.<sup>17-19</sup> Natural gas is increasingly considered to be a promising fossil fuel in  
63 China in the transition to renewable sources. It is regarded as a fuel that can reduce  
64 concentrations of greenhouse gases (GHG) and PM and its precursors (mainly SO<sub>2</sub>  
65 and NO<sub>x</sub>).<sup>20</sup> Official data show that Chinese domestic proven recoverable reserves of  
66 (conventional) natural gas are 1.5% of the world total, and as such have been viewed  
67 as a luxury. However, the past decade has witnessed the rapid development of new  
68 technologies allowing the widespread recovery of natural gas from shale formations in  
69 the US and this has brought about economic revival during the 2008-2009 global

70 financial crisis and has also reshaped the energy landscape of the US with profound  
71 geopolitical implications.<sup>21</sup> It is also worth noting that there is continuing concern  
72 about the adverse environmental risks related to air, water, and geology as well as  
73 public health from shale energy development which highlights the importance of  
74 effective governance.<sup>22, 23</sup>

75 A study shows that China has a total of 25.08 trillion cu m of proven reserves of  
76 shale gas, equivalent to nearly 200 times its annual gas consumption.<sup>24</sup> Mounting  
77 public pressure regarding air pollution is pushing the government to embrace natural  
78 gas to reduce atmospheric (e.g., SO<sub>2</sub>, NO<sub>x</sub>, primary PM) emissions. However, China  
79 is still in the nascent stage of shale gas development and the shale gas revolution is  
80 still a dream. One of the unanswered questions behind this proposed development is  
81 to what extent natural gas can achieve improvements in air quality. Although we have  
82 witnessed several successful examples of improvements in air quality (e.g., during the  
83 2008 Beijing Olympic Games and the 2010 Shanghai World Expo) after introducing a  
84 series of aggressive emissions control plans (including phasing out coal-fired power  
85 plants, powering more cars and buses with natural gas, and raising standards for  
86 vehicle emissions),<sup>25-29</sup> a city-wide systematic assessment of the benefits to air quality  
87 from switching to natural gas is clearly lacking.

88 Xinjiang province in NW China is known for its vast oil and gas reserves and has  
89 become the biggest energy base in China. Since 2011 Urumqi, the capital city of  
90 Xinjiang, has implemented a large-scale policy of shifting from coal to natural gas to  
91 improve temporarily its air quality during the winter heating period (usually from 15  
92 October to 15 March the following year). By taking advantage of this unique  
93 opportunity, we conducted a study over four consecutive years (2011-2014) to  
94 examine the relationships between substantial changes in energy use and changes in

95 levels of polluting gases and PM concentrations in an attempt to provide solid  
96 evidence for the potential role that shale gas might play in the national air quality  
97 control strategy in the future.

## 98 **Materials and Methods**

### 99 *Site description*

100 Sampling was conducted at Shengdisuo (SDS) (43°51'N, 87°33'E, 775 m above mean  
101 sea level) in Urumqi city, Xinjiang Uygur Autonomous Region, northwest China (Fig.  
102 S1, Supporting Information). Urumqi has a population of 2.2 million with a total area  
103 of approximately 14000 km<sup>2</sup> and is surrounded by the Tianshan Mountains. The SDS  
104 site is an urban monitoring site surrounded by a business district, residential areas and  
105 major roads. The sampling site is about 100 m west of a heating supply station which  
106 supplies heating from mid-October every year. Heating in winter with natural gas  
107 gradually replaced coal in the main city of Urumqi during the 2013 to 2014 heating  
108 period (Fig. S2, Supporting Information).

### 109 *Sampling procedure and sample analysis*

110 Airborne PM<sub>2.5</sub> were sampled using a particulate sampler (TH-16A, Tianhong Inc.,  
111 Wuhan, China) with a flow rate of 16.7 L min<sup>-1</sup>, and 25-28 daily samples of PM<sub>2.5</sub>  
112 were collected at SDS site during the month of January in 2011, 2012, 2013 and 2014.  
113 The sampler was placed about 2 m above the ground and ran for 24 h to obtain a  
114 particulate matter sample on 47 mm quartz filters (Whatman, Maidstone, UK). Before  
115 and after sampling, each filter was conditioned for at least 24 h inside an artificial  
116 climate chamber at a relative humidity of 50% and a temperature of 25 °C, and then  
117 weighed (Sartorius, Göttingen, Germany; precision 10 µg). PM<sub>2.5</sub> mass concentrations  
118 were determined from the mass difference and the sampled air volume. Each sampling  
119 filter was extracted with 10 ml deionized water (18.2 MΩ) by ultrasonication for 30

120 min, and the extract solution was filtered through a syringe filter (0.22  $\mu\text{m}$ , Tengda  
121 Inc., Tianjin, China) then stored in a refrigerator. Ammonium and nitrate in  $\text{PM}_{2.5}$   
122 were measured with a continuous flow analyzer (AutoAnalyzer 3, Germany), sulfate,  
123 chloride and the major cations ( $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$ , and  $\text{Na}^+$ ) by an ion chromatography  
124 system (ICS5000, Dionex, USA), and metal (loid) elements Cr, As, Ni, Mn, Cu, Cd,  
125 Pb and Al by ICP Mass Spectrometry (ELAN DRC II, PerkinElmer, USA). However,  
126 only ammonium and nitrate were measured in  $\text{PM}_{2.5}$  samples in January 2011.  
127 Monthly mean air temperature, wind speed, relative humidity and precipitation in the  
128 month of January in 2011, 2012, 2013 and 2014 at the SDS site are shown in Fig. S3  
129 and synoptic weather maps at the surface (1000 mb) around Urumqi during the same  
130 periods are given in Fig. S4 (Supporting Information), data downloaded from the  
131 Internet.<sup>30</sup>

#### 132 *Quality Assurance/Quality Control*

133 We analyzed three field blanks at every batch of samplers to monitor for  
134 contamination or interferences. Sample concentrations were determined from external  
135 calibration curves prepared at concentrations ranging from 1 to 1000  $\mu\text{g L}^{-1}$  for As, Cr,  
136 Mn, Ni, Cu, Cd, Pb and Al, and 0.5 to 50  $\text{mg L}^{-1}$  for  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$  and  
137  $\text{Ca}^{2+}$ , and 0.4 to 2.0  $\text{mg L}^{-1}$  for  $\text{NH}_4^+$  and  $\text{NO}_3^-$ . The limits of quantification were  
138 restricted to water soluble ions or metals and the limits of detection were  $\pm 0.01 \text{ mg}$   
139  $\text{L}^{-1}$  for major anion and cation ions, and  $\pm 10 \text{ ng L}^{-1}$  for metal elements. The lab  
140 belongs to Chinese State Key Laboratory for Oasis and Arid Ecosystems and has a  
141 complete quality control system. We have monitored the blank (treated syringe filters  
142 without sampling) and standard (designed specific concentrations of various ions and  
143 metal elements) samples at each measurement event. Normally, the results from the  
144 blank samples were around or below the detection limits while the differences

145 between the measured and 'theoretical' results from the standard samples were  
146 controlled to be lesser than  $\pm 5\%$ .

#### 147 *Statistical analysis*

148 Values of  $PM_{2.5}$ ,  $NH_4^+$ ,  $NO_3^-$ ,  $SO_4^{2-}$ ,  $Cl^-$ ,  $Na^+$ ,  $K^+$ ,  $Mg^{2+}$ ,  $Ca^{2+}$ , Cr, As, Ni, Mn, Cu, Cd,  
149 Pb and Al concentrations in each month at SDS site are shown as mean  $\pm$  standard  
150 error (s.e.). All statistical analysis (Pearson correlation analysis and one-way analysis  
151 of variance) was performed using the SPSS 16.0 statistical package (SPSS Inc.,  
152 Chicago, IL).

### 153 **Results**

#### 154 *Mass concentrations of $PM_{2.5}$*

155 As shown in Fig. 1, daily  $PM_{2.5}$  concentrations ranged from 101 to 568, 69.8 to 688,  
156 35.6 to 265 and 19.2 to 207  $\mu g m^{-3}$  in January 2011, 2012, 2013 and 2014,  
157 respectively. The monthly average  $PM_{2.5}$  concentrations at SDS site were 322 ( $\pm 26.1$ ),  
158 323 ( $\pm 37.6$ ), 120 ( $\pm 10.1$ ) and 78.9 ( $\pm 8.1$ )  $\mu g m^{-3}$  in January 2011, 2012, 2013 and  
159 2014, respectively. Compared with the average of January 2011 and 2012, monthly  
160 mean  $PM_{2.5}$  concentrations in January 2013 and 2014 decreased by 62.8 and 75.5%,  
161 showing a highly significant decline ( $P < 0.01$ ). We also found similar decrease in  
162  $PM_{2.5}$  in Winter (from October in the first year to April in the next year) in 2012/2013  
163 and 2013/2014 compared with in 2010/2011 and 2011/2012 (Fig. S5, Supporting  
164 Information). We summarized weather condition (wind speed, relative humidity and  
165 air temperature) for several groups and compared  $PM_{2.5}$  concentrations in January  
166 from 2011 to 2014 (across four years) under the same or similar weather conditions  
167 (Fig. 2). The results reveal significant decrease in  $PM_{2.5}$  levels in 2013 and 2014  
168 compared with 2011 and 2012 at the same wind speed, relative humidity and/or air  
169 temperature in most cases.

170 *Concentrations of particulate water-soluble inorganic ions, arsenic and metal*  
171 *elements*

172 Concentrations of particulate water-soluble inorganic ions and metal elements in  
173 PM<sub>2.5</sub> at the SDS site in January 2012, 2013 and 2014 are shown in Figs. 3 and 4.  
174 Most of the water-soluble inorganic ion (e.g., NH<sub>4</sub><sup>+</sup>, NO<sub>3</sub><sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, Cl<sup>-</sup>, Na<sup>+</sup>, K<sup>+</sup>, Mg<sup>2+</sup>,  
175 Ca<sup>2+</sup>) concentrations decreased significantly ( $P<0.01$ ) in January 2013 and 2014  
176 compared with those in January 2012, with the sole exception of K<sup>+</sup>. Similarly, metal  
177 (Cr, Mn, Ni, Cu, Cd, Pb and Al) and arsenic (As) concentrations decreased  
178 significantly in January 2013 and 2014 compared with January 2012 ( $P<0.01$ ).

### 179 **Discussion**

180 Daily PM<sub>2.5</sub> concentrations ranged from 19.2 to 688 µg m<sup>-3</sup> in January from 2011 to  
181 2014 at the SDS site in Urumqi. The Chinese second class standard of daily PM<sub>2.5</sub>  
182 concentrations is 75 µg m<sup>-3</sup>. The concentrations of PM<sub>2.5</sub> in all the 27 days during  
183 which samples were collected in January 2011 exceeded the Chinese second class  
184 standard of Ambient Air Quality Standard. Also, twenty-four day PM<sub>2.5</sub> concentrations  
185 during the 25 days of monitoring in January 2012 exceeded the second class standard  
186 of Ambient Air Quality for the PM<sub>2.5</sub> Standard. By comparison, the situation of PM<sub>2.5</sub>  
187 pollution changed in January 2013 and 2014. Only 6 days of PM<sub>2.5</sub> concentration  
188 measurement in 28 days of monitoring in January 2013 and 12 days during 26 days in  
189 January 2014 exceeded the second class standard of Ambient Air Quality Standard.  
190 Both monthly PM<sub>2.5</sub> concentrations and daily PM<sub>2.5</sub> concentrations in January 2011  
191 and 2012 were significantly higher than those in January 2013 and 2014. We analyzed  
192 the meteorological factors in January of 2011, 2012, 2013 and 2014 (Fig. S3,  
193 Supporting Information) and found significantly low temperature in January 2011,  
194 high relative humidity in 2012, high wind speeds and relatively low precipitation in

195 2013 compared with the same month (January) in the other three years. However, we  
196 observed that weather data for at least one year in each group (2011-2012 or  
197 2013-2014) were not significantly different from the other group when we compared  
198 any single weather parameter in January 2011 and 2012 with January 2013 and 2014.  
199 In addition, we found the same significant decreasing trend for PM<sub>2.5</sub> levels in January  
200 2013 and 2014 compared with the same period of 2011 and 2012 when we grouped  
201 and compared all monitoring days in different years based on similar weather  
202 conditions (e.g., wind speed, relative humidity and air temperature) (Fig. 2). For  
203 example, PM<sub>2.5</sub> concentrations decreased when the wind speed increased from > 1 m  
204 s<sup>-1</sup> to > 2 m s<sup>-1</sup> during the January from 2011 to 2014, showing that winds were  
205 conducive of the spread of PM<sub>2.5</sub>. However, under the same or similar wind speed,  
206 PM<sub>2.5</sub> concentrations were significantly lower in January 2013 and 2014 than in  
207 January 2011 and 2012 in most cases. Therefore it can be inferred that meteorological  
208 conditions are not the main factors responsible for the significant changes in PM<sub>2.5</sub>  
209 concentrations. Synoptic weather maps at the surface (1000 mb) of northwest China  
210 (Fig. S4) show that uniform high pressure and low wind speed prevail over Urumqi  
211 through January of each year, further indicating that local pollutant emissions  
212 dominate the pollution evolution in our study periods.

213 The large-scale project “shifting from coal to natural gas” was implemented after  
214 the 2012-2013 heating season. The natural gas heating area occupied only a small part  
215 of the total heating area during the 2010-2011 and 2011-2012 heating seasons, and in  
216 the 2012-2013 heating season the natural gas heating area occupied 76% of the total  
217 heating area, and heating with natural gas gradually replaced coal in the main city of  
218 Urumqi during the heating period from 2013 to 2014 (Fig. S2, Supporting  
219 Information). Since the implementation of the project “shifting from coal to natural

220 gas”, the consumption of natural gas has increased rapidly during the heating season  
221 (Figs. S6 and S7, Supporting Information). Meanwhile, coal consumption has  
222 decreased by about 5,000,000 tons, sulfur dioxide emissions (SO<sub>2</sub>) by about 35,000  
223 tons and soot by about 17,000 tons in the 2012-2013 heating season compared with  
224 the 2011-2012 heating season. A further coal consumption saving up to 7 million tons  
225 will be achieved in the 2013-2014 heating season.<sup>31</sup> We can conclude that heating  
226 with natural gas as a replacement for coal can significantly reduce the winter  
227 concentrations of PM<sub>2.5</sub> in Urumqi.

228 Coal combustion has been the major source of PM<sub>2.5</sub>.<sup>32</sup> In our study the  
229 concentrations of PM<sub>2.5</sub> were reduced by 62.8% and 75.6% after the introduction of  
230 heating with natural gas in January 2013 and 2014 instead of coal in January 2012.  
231 Although the project “shifting from coal to natural gas” has significantly reduced the  
232 concentration of PM<sub>2.5</sub>, pollution levels are still very high in Urumqi. PM<sub>2.5</sub>  
233 concentrations in Urumqi are much higher than those in Bishkek, where monthly  
234 PM<sub>2.5</sub> concentrations average only 11.7 μg m<sup>-3</sup>.<sup>33</sup> Both Urumqi and Bishkek are  
235 located in the northern Tianshan Mountains, central Asia. The monthly PM<sub>2.5</sub>  
236 concentrations in Urumqi are moderate compared to other cities in China. The PM<sub>2.5</sub>  
237 concentration (120 μg m<sup>-3</sup>) in January 2013 (after the shift from coal to natural gas for  
238 winter heating) in Urumqi was lower than that in Beijing (158 μg m<sup>-3</sup>) or Xi'an (345  
239 μg m<sup>-3</sup>) but was still higher than in Shanghai (90.7 μg m<sup>-3</sup>) or Guangzhou (69.1 μg m<sup>-3</sup>)  
240 during the same period.<sup>34</sup>

241 Together with the reduction in PM<sub>2.5</sub> concentrations the water-soluble chemical  
242 components in PM<sub>2.5</sub> (except for K<sup>+</sup> ions) were significantly reduced (Fig. 3). K<sup>+</sup> is  
243 derived mainly from biomass burning.<sup>20</sup> It follows that heating with natural gas or  
244 coal will not significantly influence the concentration of K<sup>+</sup> in PM<sub>2.5</sub>.

245 Sulfate ions ( $\text{SO}_4^{2-}$ ) and nitrate ions ( $\text{NO}_3^-$ ) are formed by the oxidation of sulfur  
246 dioxide ( $\text{SO}_2$ ) and nitrogen dioxide ( $\text{NO}_2$ ).<sup>25</sup> Most of the  $\text{SO}_2$  and  $\text{NO}_x$  emissions are  
247 from coal combustion.<sup>33, 35</sup> Burning coal is known to produce much higher  $\text{NO}_x$  and  
248  $\text{SO}_2$  emissions than burning natural gas.<sup>36</sup> Compared with the 2011-2012 heating  
249 period (heating with coal), coal consumption fell by 5,000,000 tons and sulfur dioxide  
250 emissions by 200,000 tons during the 2012-2013 heating period (heating with natural  
251 gas).<sup>37</sup> The decreased  $\text{SO}_4^{2-}$  and  $\text{NO}_3^-$  concentrations in January 2013 and 2014 are  
252 attributable to heating with natural gas instead of coal.

253 In our study, we found that  $\text{NH}_3$  concentrations in January in 2013 and 2014 were  
254 significant higher than in January in 2011 and 2012 (Fig. S8, Supporting Information).  
255 Ammonium ions ( $\text{NH}_4^+$ ) were formed by the reaction of ammonia ( $\text{NH}_3$ ) with acid  
256 gases ( $\text{SO}_2$ ,  $\text{NO}_x$  and  $\text{HCl}$ ). The implementation of the project “shifting from coal to  
257 natural gas” reduced emissions of acid gases ( $\text{SO}_2$ ,  $\text{NO}_x$  and  $\text{HCl}$ ). There were not  
258 enough acid gases in the air to react with  $\text{NH}_3$  to form ammonium ions.  $\text{NH}_3$  in the air  
259 was mainly in gaseous form. We infer that supply of heating with natural gas instead  
260 of coal can significantly decrease the concentration of  $\text{NH}_4^+$  in  $\text{PM}_{2.5}$  indirectly. In our  
261 study, we found a good relationship between  $\text{SO}_4^{2-}$  and  $\text{NH}_4^+$ . The correlation  
262 coefficients were 0.997 and 0.899 in January 2012 and 2013.

263 We found a good association between  $\text{Na}^+$  with  $\text{Cl}^-$ , with correlation coefficients of  
264 0.941 and 0.785 in January 2012 and 2013. We can infer that the two ions may have  
265 the same sources. Studies by Dou et al.<sup>38</sup> suggested that burning coal can produce  $\text{HCl}$   
266 and  $\text{SO}_2$ . In order to reduce  $\text{SO}_2$  and  $\text{HCl}$  emissions,  $\text{CaO}$  and  $\text{NaHCO}_3$  are used in  
267 power stations to react with  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$ .<sup>39</sup> As a result, some PM in the forms of  
268  $\text{CaSO}_4$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{CaCl}_2$  and  $\text{NaCl}$  are produced. Natural gas combustion produces less  
269  $\text{SO}_2$  than does coal burning.<sup>36</sup> There is no evidence to indicate that burning natural gas

270 can produce HCl. Supply of heating with natural gas instead of coal can therefore  
271 decrease the concentrations of  $\text{Cl}^-$ ,  $\text{Na}^+$  and  $\text{Ca}^{2+}$  in  $\text{PM}_{2.5}$  significantly. Kong et al.<sup>40</sup>  
272 noted that coal contains a certain amount of magnesium (Mg). This can be emitted  
273 into the atmosphere together with the smoke dust during the combustion of coal.  
274 However, burning natural gas cannot lead to this problem. Supply of heating with  
275 natural gas instead of coal can therefore significantly decrease the concentration of  
276  $\text{Mg}^{2+}$  in  $\text{PM}_{2.5}$ .

277 Lead (Pb) in the urban atmosphere was derived mainly from vehicle exhausts  
278 and coal combustion.<sup>41, 42</sup> The number of motor vehicles in Urumqi was about 359  
279 000, 466 000, and 591 000 in March of 2011 and 2012 and June 2013.<sup>43, 44</sup>  
280 Theoretically, the concentration of Pb in  $\text{PM}_{2.5}$  in the atmosphere would be stable or  
281 slightly increase with the increasing number of motor vehicles. This is because [China](#)  
282 [has adopted ULP \(Un-Leaded Petrol,  \$\text{Pb} \leq 13 \text{ mg L}^{-1}\$ \) since 1 January 2000 and all](#)  
283 [petrol engines with ULP must be with the EURO III emission standard since 31](#)  
284 [December 2009. Therefore per vehicle Pb emissions will be stable but total vehicle Pb](#)  
285 [emissions may increase slightly during our study period \(2011-2014\).](#) In fact, the  
286 concentration of Pb in the atmosphere in January 2013 was significantly reduced  
287 compared with January 2012. Clearly, automobile exhausts were not a major source of  
288 Pb in the atmosphere in Urumqi. [The decrease in Pb in  \$\text{PM}\_{2.5}\$  in Urumqi city should](#)  
289 [be mainly from the decreased Pb emissions from coal combustion due to the](#)  
290 [replacement of coal by natural gas in winter heating period.](#) We conclude that coal  
291 combustion emission of Pb was the major source of the metal in the atmosphere in  
292 Urumqi. In contrast, burning natural gas does not generate emissions of Pb to the  
293 atmosphere. The concentration of Pb in  $\text{PM}_{2.5}$  in the atmosphere decreased  
294 significantly due to supply of heating with natural gas instead of coal in January 2013.

295 Compared with burning natural gas, burning coal produced heavy metal emissions  
296 (e.g., Cu, Cd, Cr, Mn, Ni, Pb), arsenic (As) and aluminum (Al).<sup>42, 45-49</sup> Supplying  
297 heating with natural gas also significantly reduces the concentration of As, Cd, Cu, Cr,  
298 Mn, Ni and Al in PM<sub>2.5</sub> (Fig. 3).

299 Natural gas comprised 4.73% and coal 68.5% of total energy consumption in  
300 2012 in China. This compares with a global average of 23.9% for gas and 29.9% for  
301 coal (Fig. S9, Supporting Information). If we increase the contribution of natural gas  
302 to the total energy consumption in China to the world average, we can reduce the  
303 consumption of coal by 751 million tons and increase the consumption of natural gas  
304 by 583.2 billion cubic meters. Thus, we can reduce emissions of 4.57 million tons of  
305 SO<sub>2</sub>, 2.87 million tons of NO<sub>x</sub> and 0.734 million tons of dust. Compared with the  
306 national emissions of SO<sub>2</sub>, NO<sub>x</sub> and dust, increasing the proportion of natural gas  
307 consumption can reduce SO<sub>2</sub> emissions by 21.6%, NO<sub>x</sub> emissions by 12.3% and dust  
308 emissions by 5.94% (Table 1) and this will help to improve atmospheric quality. If we  
309 increase the proportion of natural gas consumption from 4.73% to 23.9%, this will  
310 result in an additional consumption of 583.2 billion cubic meters of natural gas every  
311 year. The proven recoverable reserves of natural gas are only 3.1 trillion cubic meters.  
312 Fortunately, China has rich shale gas resources for which the proven recoverable  
313 reserves are 25.08 trillion cubic meters<sup>24</sup>. Shale gas is therefore likely to occupy an  
314 important place in the energy supply in the future and may represent an ideal  
315 transitional energy source which can reduce air pollution. Of course, the adverse  
316 effects of shale energy development (e.g., fugitive emissions of methane, groundwater  
317 contamination) should be considered carefully when large scale exploration of shale  
318 gas in the future.<sup>50</sup> Meanwhile the proportion of other clean energy sources in  
319 particular renewable energy sources (e.g., solar, wind and biomass energy) should also

320 be increased for better air quality in the future.

321 Therefore, government decisions or policies will play a positive role in improving  
322 air quality. It would be worthwhile for China, especially in rapidly developing regions  
323 (e.g. the Yangtze River Delta, the Pearl River Delta and the North China Plain) to take  
324 more stringent measures (e.g. stricter emission standards and closure of heavily  
325 polluting enterprises) to control the emission of pollutants. Our case study reveals that  
326 haze in China will be greatly alleviated in the near future if we take action now.

 524 significantly different at p<0.01).

Coal			Natural gas						
751 million tons (coal saving potential if its use reduced to 49.3% of national energy supply)			583.2 billion cubic meters (additional gas required if its use raised to 23.9% of national energy supply)						
Emission factor (T / tce) <sup>1,2</sup>	Removal efficiency (%) <sup>3-5</sup>	Emissions (million tons)	Emission factor (T / one million cubic meters) <sup>2</sup>	Removal efficiency (%)	Emission (million tons)	Reduction (million tons)	National emissions in 2012 (million tons) <sup>6</sup>	Reduction rate (%)	
SO <sub>2</sub>	0.016	60.8	4.71	0.63	60.8	0.144	4.57	21.18	21.6
NO <sub>x</sub>	0.009	40.0	4.06	3.40	40.0	1.19	2.87	23.38	12.3
Dust	0.01	90.0	0.75	0.29	90.0	0.0167	0.733	12.36	5.94

525 **Table 1.** SO<sub>2</sub>, NO<sub>x</sub> and dust emissions from reduced coal and increased natural gas, SO<sub>2</sub>, NO<sub>x</sub> and dust reduction and reduction rate
