7

8 Abstract

9 Previous research has often highlighted the physiological decline an athlete will be subjected
10 to as they age. However, whilst some studies have evaluated a large sample of athletes at a
11 given age, few studies have evaluated a single athlete over a much longer period of time in
12 sports such as cycling. This study assessed the time trial performances of a multiple national
13 record holding male amateur cyclist from when they were aged between 37 to 75 years of age.
14 488 of their individual performances over nearly four decades were contrasted against a
15 statistically generated baseline of athletes that they competed against during these events. The
16 results indicated a relatively stable level of performance from aged 37-52 years of age.
17 However, a noticeable decline began to take place at aged 61 which then degraded sharply at
18 aged 70. Interestingly, the athlete did not exhibit a permanent reduction in their average
19 velocity in their best 16.1km and 40.2km time trial performances until aged 70. This suggests
20 that despite the physiological decline that will eventually reduce a riders competitiveness, this
21 case study demonstrated that it is feasible to continue the pursuit of personal records until
22 relatively late in life.

25

26 1. Introduction

27 Within competitive cycling, a unique
28 discipline is the 'individual time trial'. This
29 cycling discipline requires a rider to cover a
30 fixed distance at their highest obtainable
31 average velocity. To achieve this requires
32 the highest possible physiologically
33 generated power (Jeukendrup et al. 2000),
34 the optimised reduction of the aerodynamic
35 drag of the rider and bicycle (Lukes et al.
36 2005) and the maximised mechanical
37 efficiency of the cyclist's drivetrain
38 (Zamparo et al. 2002). Insofar as the athletes
39 who may compete in cycling time trials,
40 'masters athletes' are typically regarded as
41 being older than 35 years of age and

42 compete in organized forms of sport for
43 older adults (Reaburn et al. 2008). An age-
44 related decline in performance by masters
45 athletes are well cited and have been
46 observed across several endurance sports
47 (Reaburn et al. 2008) including cycling upto
48 60 years of age (Ransdell et al. 2009) and
49 across a variety of age groups (Peiffer 2008).
50 These declines have been reported as
51 curvilinear from age 35 years until
52 approximately age 60-70 years. The trend
53 then changes to those that are negatively
54 exponential thereafter (Reaburn et al.
55 2008). Whilst comparing a group of athletes
56 at a range of ages is a typical approach to
57 illustrate an age-based decline in
58 performance, there is also value from
59 obtaining longitudinal studies of specific

60 athletes (Rathwell & Young 2015) or rider
 61 case studies over large periods of time
 62 between formal testing (Mujika 2012)
 63 despite these being rarely investigated. This
 64 may be pertinent when it is considered that
 65 master's competitions are actually seeing a
 66 greater source of performance improvement
 67 than those of elite athletes in their prime
 68 (Akkari et al. 2015). As a result, this may
 69 suggest that future findings in this field may
 70 revise the conclusions of older studies. This
 71 case study will evaluate the performance of
 72 a time-trial cyclist over a relatively long
 73 period of time.

74

75 2. Materials and Methods

76 Subjects

77 A male cyclist acted as the basis for this case
 78 study. The subject was geographically
 79 located in the UK. The subject was 76 years
 80 of age with four decades of consistent
 81 competitive experience in UK-based cycling
 82 time trials. They were defined as an
 83 'amateur cyclist' in that they did not use
 84 competitive cycling as a means of
 85 employment or income and would race
 86 throughout a calendar year at events of their
 87 choice and preference. The subjects'
 88 perceived standard as a racing cyclist was
 89 judged as high based upon them holding
 90 several national age group records held
 91 between the ages of 68-74 for the formal 10
 92 mile (16.1km) or 25 mile (40.2km) time trial
 93 distances in the UK. The formal race
 94 distances are defined in miles in the UK but
 95 will be expressed in kilometres for the
 96 purposes of this paper.

97 Within the UK, the consistent format of
 98 competitive cycling time trials involves
 99 riders competing individually over several
 100 fixed race distances of 10-100 miles in length
 101 or using time constrained formats of 12 and
 102 24 hours in duration
 103 (www.cyclingtimetrials.org.uk). Whilst the
 104 distance or duration remains the same, the
 105 race environment itself that a UK-based time
 106 trial cyclist will race over is an open
 107 environment. This means any performance
 108 could be influenced by external factors such

109 as weather, road surface condition,
 110 gradients and the influence of any passing
 111 motor vehicle traffic. However, whilst these
 112 conditions are not standardised or definable
 113 per se', their philosophical influence have
 114 remained consistent in principle since the
 115 sports inception. This particular sporting
 116 environment has seen performance analysis
 117 applied to it previously (Dyer et al. 2016).

118

119 Methodology

120 The subject's results in cycling time trials
 121 from 1980-2020 were used as the basis of this
 122 analysis. The results were sourced from the
 123 time trialling governing body's web page for
 124 this participant's geographical home region
 125 (www.southdc.org.uk). The inclusion
 126 criteria of the participant's results were
 127 deemed that of any race that was potentially
 128 open to any competitors, irrespective of
 129 gender or age and was not that of a team
 130 based event such as a team time trial.
 131 Finally, the events analysed only comprised
 132 those that were competed over a fixed
 133 distance but not those of a fixed duration.
 134 This study obtained institutional ethical
 135 approval, informed consent from the
 136 participant and the results used for this
 137 analysis existed in the public domain.

138

139 Statistical Analysis

140 The participant's time trial results were
 141 statistically compared to that of an
 142 established baseline to assess the positive or
 143 negative changes in their performance.
 144 Traditionally, this can be achieved by
 145 comparing an athlete's performance to
 146 world or national records (Ransdell et al.
 147 2009) or the use of metrics such as the riders
 148 power output. However, the ability to
 149 consider age relies on national age-related
 150 records being known retrospectively at the
 151 time the participant competed in each of
 152 their events but these were not available.
 153 Secondly, the means to record power 'in the
 154 field' by cyclists was not feasible four
 155 decades ago. Instead, the mean average of
 156 the ten fastest finishers of each event was
 157 utilised to provide a statistically calculated
 158 sociological baseline. A similar approach has
 159 been previously used to compare general

160 athletic performance of an event against its
 161 medal podium (Dyer et al. 2015). To then
 162 compare the participants, the Performance
 163 Improvement Index (PII) has been used as a
 164 means to compare cycling performance
 165 (Haake 2009). The PII primarily assesses the
 166 change in performance from one data point
 167 to another. When considering timed events
 168 such as cycling time trials, Haake defines the
 169 PII as:

170

$$PII = \left[\left(\frac{t_1}{t_2} \right)^2 - 1 \right] \times 100$$

171

172 For this study, the PII between the mean of
 173 the 10 fastest riders (t_1) and the participant
 174 (t_2) was calculated for each individual event.
 175 This was deemed the Relative Performance
 176 Improvement Index (RPII). Additionally, to
 177 account for any changes the participant may
 178 have made in their training, event emphasis
 179 or technology, the mean of the best six RPII
 180 results from each year were also selected for
 181 analysis, with any years with less than six
 182 events then discarded.

183 To help ascertain what consistency existed
 184 in the improvements or decline in the
 185 participants' performance, the RPII of the
 186 best annually achieved 16.1km and 40.2km
 187 race distances was checked for statistical
 188 significance using a students paired t-test
 189 ($\rho < 0.05$).

190

191 3. Results

192 The participant completed 488 eligible
 193 time trial events during the time period
 194 of 1981-2019. The participant's results
 195 of their RPII from 37-75 years of age are
 196 illustrated in figure 1.

197

198 [INSERT FIGURE 1 HERE]

199

200 The participant experienced a
 201 noticeable decline in their performance
 202 over the evaluated time period. The
 203 participant remained positively
 204 competitive vs those in 1st-10th until
 205 approximately 52 years of age. The
 206 participant then seemed to undertake a
 207 reduced level of competitive
 208 participation and performance in the
 209 sport from ages 54-57. From ages 58-68
 210 their performance seemed to return to a
 211 positive level but lower than that of
 212 when 37-52 years of age. From the age
 213 of 65, their performance level indicates
 214 a shift to being predominantly negative
 215 yet relatively stable until then
 216 degrading markedly from age 70
 217 onwards. The six best RPII annual
 218 performances are shown in figure 2.

219

220 [INSERT FIGURE 2 HERE]

221

222 Figure 2 shows a reduced, yet still
 223 positive RPII from 52 years of age. After
 224 a short period of low or no race
 225 participation, it shows a progressively
 226 reducing RPII from age 58-69 years of
 227 age. The shift to a permanently
 228 negative level of performance is seen at
 229 age 70-74.

230 The participant's best annual
 231 performance over the 16.1km racing
 232 distance is shown in figure 3. In this,
 233 their best average velocity achieved at
 234 each age is shown against the RPII with
 235 a 6-point polynomial line of best fit
 236 added to both traces.

237

238 [INSERT FIGURE 3 HERE]

239

240 In figure 3, the participant sees a
 241 general increase in race-based average
 242 velocity until 70 years of age before a

243 noticeable decline takes place.
 244 Conversely, the RPII is in a generally
 245 progressive decline demonstrating a
 246 reduction in the participant's
 247 competitiveness. The obtained velocity of
 248 the participant's age over the 40.2km
 249 race distance is shown in figure 4.

250

251 [INSERT FIGURE 4 HERE]

252

253 In figure 4, the decline in their
 254 performance, exhibited by the RPII,
 255 shifted progressively negative from 70
 256 years of age. However, the participant
 257 was able to obtain average velocities
 258 that were in the range of 44-45km/h
 259 from age 36 up to age 70 and even
 260 exceeded this at age 68.

261 Finally, both the 16.1km and 40.2km
 262 best annual performance RPII's shown
 263 in figures 3 and 4 were not significant
 264 from each other ($p=0.9$).

265 4. Limitations

266 There are two main limitations in this case
 267 study. The first is that the physiological and
 268 performance characteristics of the
 269 participant were not stated in the paper and
 270 would have likely changed over time. These
 271 would have included aspects such as their
 272 power output, VO₂ max, body-mass and
 273 overall aerodynamic drag. However, the
 274 technology to record these was not
 275 available, not known or not feasible over the
 276 four decade time period.

277 Secondly, the use of a statistically generated
 278 baseline to compare the participant against
 279 does not account for any sociological
 280 changes that may have occurred in the sport
 281 over four decades. These could include
 282 changes in the sports general performances,
 283 or participation levels of this cycling
 284 discipline as well as specific riders entering
 285 or leaving the sport.

286 5. Discussion

287 In the case of this study, as expected, the
 288 participant has experienced a noticeable
 289 decline in their performance. However, they
 290 remained competitive with their
 291 performances remaining relatively stable
 292 and undiminished until approximately 52
 293 years of age. It has been stated that whilst
 294 cycling performance does progressively
 295 decline, it can be well maintained in
 296 master's competitions until their late 60s
 297 (Baker & Tang 2010). Aside from a period of
 298 reduced competition from when the
 299 participant was aged 54-57, that observation
 300 was supported by this case study. The clear
 301 negative degradation in performance took
 302 place from age 70 onwards which supports a
 303 general commentary on ageing time triallists
 304 made by Davison (2012 pg 234). It is
 305 conceded that the causes of the decline in
 306 the subject's performance post 70 years of
 307 age are likely to be complex and could
 308 equally be caused by social, economic, and
 309 lifestyle factors rather than purely that of
 310 their physiological degradation as well as a
 311 reduction in both training and competition.
 312 These potential issues are a limitation of this
 313 case study. Such confounding factors have
 314 also been conceded in master's studies
 315 before (Baker & Tang 2010). However, it
 316 should be noted that the participant won
 317 and held the age-based national records
 318 over a variety of race distances at age 68-74
 319 (<https://www.vtta.org.uk/records>) whilst
 320 this decline was taking place. This infers that
 321 the participant was likely intending to be
 322 competitive at this point, despite an obvious
 323 decline in their performance.

324 Figure 1 illustrated several occasions
 325 whereby the participant achieved a year
 326 possessing mainly negative results that were
 327 then followed by a return to better
 328 performances in ensuing years. The
 329 participant suggested these were due to
 330 changes in training methodology or other
 331 sociological factors. Whilst it is well cited
 332 that age-related performance-based decline
 333 is inevitable, the multi-faceted nature of
 334 performance cycling indicated in the
 335 introduction of this paper does mean that

336 such decline was slowed or even
337 temporarily reversed by the participants'
338 interventions.

339 The PII has been successfully used to detect
340 changes in sports technology (Haake 2009).
341 In the case of time trialling, a notable
342 innovation was the introduction of 'tri bars'
343 during the 1980's. These changed the
344 traditional method of riding a bicycle with
345 relatively wide handlebars to assuming
346 more of a 'tuck' with the hands positioned
347 together and in front of the rider. This
348 innovation saves rider energy at the same
349 speed or increases their velocity for the same
350 energy output (Sheel et al. 1996). It should
351 be noted that the participant confirmed that
352 they started using these in 1986 but none of
353 the graphs showed a noticeable increase in
354 race average velocity around this time. The
355 reason for this only highlights the
356 confounding variables such as weather or
357 traffic conditions when competing in an
358 open environment. As a result, the trends in
359 this case study should be considered more
360 important than any specific absolute values.

361 The result of the t-test suggests that their
362 performance relative to their peers in both
363 the 16.1km and 40.2km best annual
364 performances were not significant from each
365 other, irrespective of these different race
366 distances. This suggests that any year to
367 year RPII changes were unilateral to the
368 athlete and not event specific when
369 considering race durations ranging from
370 20mins to circa one hour. When considering
371 the participants best annual results of the
372 16.1km and 40.2km race distances, the
373 participant surprisingly achieved some of
374 their highest average velocities as they aged
375 into their 60's, yet past the point where their
376 RPII had already shown degradation. This
377 could have been due to technological
378 advancement, environmental changes (such
379 as more favourable courses in terms of
380 topography), atmospheric-based decreases
381 in aerodynamic drag, environmental
382 changes (such as changes in passing traffic
383 levels) or combinations of these thereof.
384 Thereby it is conceded that there is plenty of
385 scope for random or confounding factors in

386 cycling performance. Nonetheless, the
387 perceived success on time trial cycling by its
388 athletes could be judged in two different
389 ways. If the goal is to remain competitive
390 against other participants, there is obviously
391 a point where this will degrade and that this
392 case study fell broadly in line with previous
393 research and a subsequent sharp loss of
394 performance at aged 70 (Reaburn et al.
395 2008). However, if the primary aim is their
396 pursuit of the *highest possible average velocity*
397 *they can achieve*, this may still be achievable
398 at a later point in life than the physiological
399 decline alone has previously suggested.
400 Provided the athlete is aware of the
401 composite relationship between their
402 training, equipment and environmental
403 factors, they may be able to stimulate, slow
404 down or even improve their personal level
405 of performance. Since many master athletes
406 may seek a personal record as a priority, this
407 outcome could be seen favourably.

408

409 6. Conclusion.

410 This paper provided more evidence of the
411 known physiological decline that takes place
412 by masters cyclists in the form of a four
413 decade-long case study. Despite this decline,
414 this case study has shown how late in life a
415 good level of relative performance was held
416 and this may provide a useful case study for
417 coaches and practitioners alike to note.
418 Furthermore, it is also worth considering
419 that athletes and coaches may be able to
420 orchestrate a temporary reduction in this
421 decline provided they remain sensitive and
422 proactive in their awareness and
423 manipulation of the other performance
424 factors that occur in cycling time trials
425 besides just that of the riders' physiology.

426
