M. Finance, Curtin University, 2012

This thesis is presented for the degree of

Doctor of Philosophy

Murdoch Business School

Murdoch University

Perth, March 2020

DECLARATION

I, Le Thi Ngoc Quynh, declare that this thesis has been composed solely by me, and that has not been submitted, in whole or in part, in any previous application for a degree. Except where stated otherwise by reference or acknowledgement, the work presented is entirely my own.

Signature: Le Thi Ngoc Quynh

Date: 31 March 2020

ACKNOWLEDGEMENTS

I would like to say a big thank to everyone who has supported and convoyed me through my PhD course in the Murdoch Business School, Murdoch University. Words cannot express how grateful I am to my principal supervisor, Dr Ariful Hoque. I am indebted to my principal supervisor for his precious guidance, assistance, motivation, and advice. I would also like to express my thankfulness to my co-supervisors, Professor Dominic Gasbarro, and Dr Kamrul Hassan, for their valued assistance during my PhD candidature.

I would like to give thanks to my ADVIS-CTEE, Associate Professor. Grant Cullen for his support in my study, and to Ms. Mellisa Lewis for her valuable assistance, advise and motivation. I am also grateful to Mr. Dale Banks, Ms. Ashleigh Roberts, Ms. Julia McMath, and Ms. Sandy Clark for their administrative support and friendly cooperation, which helps me to be organised all over my PhD course.

Special thanks to my husband and my daughter for their support and understanding for a long journey to complete my study. This thesis is a testament to their unconditional love and encouragement.

I appreciate all your support; without support, it would be impossible to complete my thesis.

ABSTRACT

This research analyses the intraday implied volatility (IV) for pricing currency options. It conducts analyses in three steps. First, estimates at-the-money IV using the price of options with one-month, two-month, and three-month maturity during the opening, midday, and closing period of a trading day. Second, the Mincer-Zarnowitz regression test assessing the performance of IV to forecast the volatility of the underlying currency of options for the within-week, one-week, and one-month forecast horizon. Third, mean absolute error (MAE), mean squared error (MSE), and root mean squared error (RMSE) measures evaluating the performance of IV to estimate the price of currency options for the within-week, one-week, and one-month estimate horizon. It employs Australian dollar, British pound, Canadian dollar, Euro, and Swiss franc options trading from 01 January 2010 to 31 December 2017. This study reveals four critical findings. First, three-month maturity IV does not contain useful information about future volatility of the underlying currency and pricing currency options. Second, IV incorporates all information is not relevant to compute the price of currency options for less than a week estimate horizon. Third, IV of the closing period on Monday or Tuesday subsumes most of the essential information compared to other periods of a trading day and other days of a week to forecast volatility of the underlying currency and estimate the value of currency options. Fourth, the shorter (longer) maturity IV holds vital information to price currency options for the shorter (longer) estimate horizon. The overall research findings imply that the information content embedded in one-month and two-month maturity IV is appropriate to calculate the currency options price for the one-week and one-month estimate horizon, respectively. The intraday IV approach adds a new dimension to obtain the unobservable volatility in pricing currency options accurately for the researchers and practitioners.

CHAPTER 1

Introduction of Thesis

1.1 Introduction

Foreign currency options are one of the significant developments in the financial derivative markets. The currency options do not substitute the forward or futures contracts but use as a more versatile financial derivative. It can offer the opportunities and advantages to those seeking protection from financial distress resulting from the movement of foreign exchange (FX) rate. Over the past four decades, the currency options employ as a hedging tool and for speculative purposes has significantly grown into a majority of foreign exchange activity. It can be traded on a regulated exchange where they are sold in a standardised form by managing the underlying currency contract size, strike price, and expiration date. However, over-the-counter (OTC) options are allowed for customisation of the terms of the options contract for contract size, strike price, and date of maturity.

Holding either exchange-traded or OTC currency options for hedging or speculation can be costly. The options price or premium is derived using the spot price of the underlying currency of options. It is high for in-the-money (ITM) options (call and put strike price is less and more, respectively, than the spot price). It is low for out-of-the-money (OTM) options (call and put strike price is more and less, respectively, than the spot price). Therefore, the options premium plays a significant role in determining the state of the FX market. For example, the FX market experiences a forward volatility skew due to an expensive OTM call compared to the ITM call. It indicates that FX market participants are concerned about the tight foreign currency supply and the buy call options to secure their foreign currency amount. Similarly, the reverse volatility skew is developed in the FX market when the premium of the OTM put is higher than the premium of the ITM put. It reveals that market players are generally worried about an FX market crash, and they buy put options to protect their foreign currency value.

Black-Scholes (BS, 1973) model is most commonly used to calculate European options price (Yang & Jaewook, 2011). Bhattacharya (1980) and Rubinstein (1985) report that the BS model is biased in pricing options. However, there is few models appear to be consistently superior to it (Singh & Vipul, 2015). Using the Merton (1973) version of the Black-Scholes (1973) model

(BSM), the currency options price is calculated based on six elements: current spot price, strike price, domestic currency interest rate, foreign currency interest rate, time to maturity and volatility of the underlying currency. The first five components of the BSM model are obtainable from the financial market, whereas volatility is unobservable. Volatility captures the up or down movement of the underlying FX rate, which has a significant effect on the options price. The appreciation of the FX rate leads to an increase in the call options price and a decrease in the put options price. If the FX rate decreases, the price of the calls decreases and puts increases.

Further, the volatility reflects investors' expectations about the future movement of the underlying assets' price. The volatility of the underlying asset becomes a potential problem for the model when the practitioners use it to compute the option price. Since volatility is unobservable, the error in the estimation of volatility leads to the mispricing of options (Cruz, 2008). All options pricing theory indicates that options prices should have a positive correlation with the underlying asset's volatility (Christensen & Prabhala, 1998), and the mispricing of derivatives are related to change in volatility of the underlying assets (Singh & Vipul, 2015; Tu et al., 2016). The market participants require relevant future volatility of the underlying asset for pricing options (Becker et al., 2006). Since the volatility is essential for option pricing, it is critical to explore ways to incorporate appropriate volatility measures into option pricing issues.

Errors in predicting volatility lead to the error in evaluating the fair price for the option. When the use of options as a hedging tool and for speculative purposes has surged over the past three decades, the accuracy of options pricing plays a crucial role in managing financial risk as well as trading options. The existence of mispricing affects the hedge ratio selection, hedging effectiveness, and expected hedging cost (Lai et al., 2017). When a trader uses a volatility estimate that is not equal to the actual volatility experienced during the option's lifetime, both the expected return and the risk of the trader's arbitrage portfolio are affected (Figlewski, 1989). Moreover, the options are known to provide a source of leverage for speculators because the premium is much lower than the actual underlying asset price. However, as the contract size of options is large (for example, one option contract includes 100 shares), the potential loss realized by traders is also huge for mispricing of options. Last but not least, the options mispricing influences the efficiency of the options market, which leads arbitragers to realized

arbitrage profit. Therefore, a precise measure of volatility is crucial for accurately estimating and forecasting the currency options price.

The literature categorizes the volatility forecasting methods into two streams: (i) volatility forecasts using historical information such as GARCH family model, realized volatility (RV) model and others; and (ii) volatility forecasts using information embedded from options prices, namely implied volatility (IV). Recently, the IV has received significant attention from both academicians and market practitioners. It provides the market's expectation about the future volatility of the underlying assets over the remaining life of the option contract. The options market contains a broader and richer set of information in comparison with the underlying asset's market, as options traders estimate both the past and future information for pricing options. If the options market is efficient, the IV from options price should be an unbiased and useful predictor of the actual volatility of the underlying assets (Pati et al., 2018). The IV subsumes all available, including historical information (Beckers, 1981; Brous et al., 2010; Busch et al. 2011; Garvey & Gallagher, 2012; Latane & Rendleman, 1976; Schmalensee & Trippi, 1978; Wang & Wang, 2016).

1.2 Mechanics of currency options

A currency option is a contract where the buyer has a right, but not the obligation, to buy or sell a particular currency at a specific exchange rate on or before a specified date. It provides payoffs that depend on the difference between the exercise price and the exchange rate at maturity. Currency options are one of the most widely used derivatives for corporations, individuals, or financial institutions to hedge against an adverse movement in exchange rates. There are two types of options: call and put. The call options grant the holder the right to buy an asset on a specific date at a fixed price. However, the put options give the holder the right to sell an asset by a specific date for a certain price. An options contract is alive until the date of maturity, and European options can only exercise at the maturity. However, American options holder can exercise on or before the date of maturity.

An Australian company that expects to receive 1 million US dollar (USD) of export income in two months illustrates the use of currency options. Since the company wants to convert into Australian dollars (AUD), it will have exposure to the spot rate between the AUD and the USD in two months. However, this rate is unknown in advance, and the company faces uncertainty for its future USD income. Such uncertainty leads to a challenge for the company in financial planning. The selling the USD in the forward market will eliminate this difficulty. If the two months forward rate is AUD1.2500/USD and the company decide to hedge with a forward contract at the quoted rate, the income of the company is fixed with AUD1,250,000 [USD1,000,000 x (AUD1.2500/USD)] in two months. If the company does not sell the USD in the forward market, it exposes the risk of making losses or profits. If the two months' time the spot rate is AUD1.1500/USD, converting at that rate would result in receipts of AUD1,150,000. It provides a loss of AUD100,000 (AUD1,250,000 - AUD1,150,000) in comparison with the forward hedge described above. In contrast, if the spot rate in two months' is AUD1.3500/USD, converting at that rate would result in a profit of AUD100,000 [(AUD1.3500/USD x USD1,000,000) - AUD1,250,000] relative to the forward position. It indicates that the company will have an opportunity loss of AUD100,000.

The holder of a currency option can use it as a hedging method, which (like the forward) puts a limit on the losses that are dealing at the spot rate could generate but (unlike the forward) does not eliminate all the potential profits. The reason is that the holder of the options has no obligation to exercise options at maturity. The Australian company could hedge its exposure

by buying a put option (to sell USD) at a strike price of AUD1.2500/USD, and the option premium is assumed to be AUD2000. If the spot value of USD in two months is lower than the strike price, say AUD1.1500/USD (put options are ITM), the company will exercise the option and sell USD1,000,000 at the strike price (AUD1.2500/USD) which is higher than the market price (AUD1.1500/USD). As a result, the Australian company's net proceeds will be AUD1,248,000 $[(AUD1.2500/USD) \times USD1,000,000] - AUD2000$. On the other hand, if the spot rate of the USD in two months is higher than the strike price of the option, say AUD1.3500/USD, the option is OTM, the company will not exercise the option, and its loss is only AUD2,000 premium paid for the option. However, the Australian company will sell the USD dollar at the higher market price AUD1.3500/USD, and its net proceeds will be AUD1,348,000 $[(AUD1.3500/USD) \times USD1,000,000] - AUD2000$.

In summary, the profit from the put options will be higher if the USD is weaker than the strike price. If the USD is dramatically higher than the strike price, then the loss incurred by the option holder is limited to the premium. However, net proceeds will be positive if the difference between the market price and the strike price is higher than the options premium. It clarifies the core feature of options that the holder to experience a limited loss but remains with the profit opportunity from a favourable price movement of the underlying instrument in the market.

1.3 Development of currency options market

Foreign currency options trading began in the late 1970s and early 1980s in the organised exchanges in London, Philadelphia, and Chicago. At that time, currency options were purely used by major banks for offering international clients as hedging instruments, when buying and selling a significant amount of foreign exchange. These were typically related to export and imports of goods or services that required payment at a future period in foreign currency involving a large amount of money. However, the scenario of options trading changed in the early 1990s as currency options moved into mainstream finance and were soon widely adopted on the trading floors and exchanges. The recent dramatic growth in online trading provides further motivation for the massive growth in currency options trading. Options on the physical currency are traded on some organised exchanges worldwide.

The ancestor of Euronext is the London International Financial Futures Exchange (LIFFE). In 1982, LIFFE started to take advantage of the removal of currency control in the UK in 1979. After that, it has undergone a series of mergers and takeovers. In 1992 LIFFE merged with London Traded Options Market (LTOM) and changed its name to the London International Financial Futures and Options Exchange (LIFFOE). In 1996 it merged with London Commodity Exchange (LCE). In 2002 Euronext took over LIFFOE and formed Euronext.Liffoe. Finally, by the end of 2007, it was merged with New York Stock Exchange (NYSE) and named as NYSE Euronext. This exchange currently offers options, only on Euro against the US dollar or the US dollar against the Euro. Both of these options are European style with the ticker DEX. The unit of trading is 100, and the contract size is 10,000 units of the currency.

In December 1982, the Philadelphia Stock Exchange (PHLX) started trading in standardised foreign currency options contracts in the United States. Subsequently, PHLX introduced a range of currency options aimed at retail and small traders. The exchange currently provides options on some currencies, such as the AUD, Canadian dollar (CAD), British pound (GBP), Euro (EUR), Japanese yen (JPY), and Swiss franc (CHF) settling against the USD. The contract size is 10,000 units of a currency with a minimum trade size of one. Like NYSE Euronext, these options are also European style so they can be exercised only at maturity of the contract. The Chicago Board Options Exchange (CBOE) is the largest for trading options in the USA. Recently the exchange has introduced in its website a paper trading and virtual trading

platform, which provides the traders with the opportunity to become comfortable with reading options chains, opening and closing positions, and testing strategies. Currently, the Chicago Mercantile Exchange (CME) provides currency options on CHF, JPY, CAD, and EUR against the USD. Both American and European style options are available in the CME. It is suitable for small and retail traders, as the contract size is 10,000 units of a currency, and the minimum trade size is one.

International Securities Exchange (ISE) is based in New York and operates an entirely electronic trading platform. In a strict sense, it is not an exchange; it is an electronic auction of options, which was one of the first to replace the floor-based trading systems, widely used in the late 1990s and early 2000. The ISE currently offers four currencies, GBP, EUR, CAD, and the JPY. All options are European style. Many other exchanges trade foreign currency options. However, all have some trading aspects in common. First, options are available in pairs of currencies only, and not available for cross pairs; second, specialised currency options broker trades these options; finally, since the currency options are the specialised and sophisticated instrument, one has to have some prior currency options trading experience.

The OTC market in currency options has developed significantly in the major financial centers, such as London and New York. In London, this market was started in the 1970s as the banks began to write options for three to four months' maturity to scope with the risk management requirement of customers. The trade volume was small from the earlier of the period up to 1983. Since then, the market in London has developed significantly, as many domestic and foreign commercial and investment banks expanded their options activities. The significant change in the currency options market took place throughout the 1980s. During this period, the interest of the currency options traders shifted from exchanges to OTC trading because of some unique benefits of OTC currency options over options traded in exchanges. Financial institutions are willing to write or buy options that vary by amounts (notional principal), strike price, and maturity. Although the OTC markets were relatively illiquid in the early years, the market has grown to such proportions that liquidity is now considered quite good. Firms buying and selling currency options as part of their risk management program do so primarily in the OTC market. The advantage of this market is that large trades are possible, with strike prices, expiration dates, and other features tailored to meet the needs of corporate treasurers.

Further, the foreign exchange market spans the globe, with prices moving and currencies trading every hour of every business day. As a result, the currency options trading has been growing faster among all options (currency, stock, index, and commodity) markets. It is not very easy to measure precisely the size of the currency options market as currency options are traded not only in the exchanges; also, private banks trade a considerable volume in the interbank market. However, International Settlements (BIS) provides a rough estimate by conducting a survey every three years. The trend in currency options trading experienced dramatic growth since early 1995. The BIS survey result reveals that from 1995 to 2019, the average daily OTC turnover in currency options increased from 41 to 294 billion US dollar; more than 617% has increased in 24 years.

1.4 Research objectives and hypotheses

This research aims to analyse the intraday IV for pricing currency options through (i) assessing the performance of IV to forecast the volatility of underlying currency of options, and (ii) evaluating the performance of IV to estimate the price of currency options. There is a sizeable literature investigating the information content of IV to forecast the volatility of the stock, stock index, and foreign currency, however, no significant research on the IV for pricing options. The following two (2) research objectives achieve the aim of this study.

In the previous studies, Kazantzis and Tessaromatis (2001) report that IV using JPY, GBP, CHF, CAD, and AUD has more information content based volatilities for horizons ranging from one day to three months. Kim and Kim (2003) show that the IV of the CAD, CHF, DEM, GBP, and JPY options tend to be low in the early part of the week but remain high in the latter part of the week beginning on Wednesdays. The research findings of Christoffersen and Mazzotta (2005) indicate that the IV based on the EUR, GBP, and JPY options accurately forecasts of one and three months ahead of actual volatility. They also show that the ATM call and put options price for EUR, GBP, and JPY provide mostly unbiased IV. Wang and Wang (2016) examine the information content of intraday IV using S&P500 Index options and find that the IV around noon contain more useful information regarding future volatility than IV at the market's closing. Wong and Heaney (2017) find that the information content of IV obtaining from GBP, EUR, AUD, and JPY options with one-month maturity improves the foreign exchange volatility forecast accuracy. Pati et al. (2018) examine the information content of the IV index in forecasting RV, using it as the proxy for the actual volatility. They report that the IV index contains incremental information in explaining future RV. The summary of these previous studies introduces the first research objective is to compute the IV based on the price of options with one-month, two-month, and three-month maturity during the opening, midday, and closing period of a trading day in forecasting RV of underlying currency of options for the within-week, one-week, and one-month forecast horizon.

Further, Hoque and Kalev (2015) show that intraday IV is more accurate in estimating volatility for pricing currency options. Therefore, second research objective is to compute the IV based on the price of options with one-month, two-month, and three-month maturity during the opening, midday, and closing period of a trading day in estimating the price of currency options for the within-week, one-week, and one-month estimate horizon. The within-week estimate

horizon indicates that the IV is estimated one day to four days before the date of pricing currency options. Similarly, the one-week and one-month estimate horizon imply that the IV is estimated one-week and one-month before the date of pricing currency options, respectively.

The following eighteen (18) hypotheses has been developed based on the two (2) research objectives.

For research objective one (Figure 1.1):

H1: One-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the within-week forecast horizon.

H2: Two-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the within-week forecast horizon.

H3: Three-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the within-week forecast horizon.

H4: One-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-week forecast horizon.

H5: Two-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-week forecast horizon.

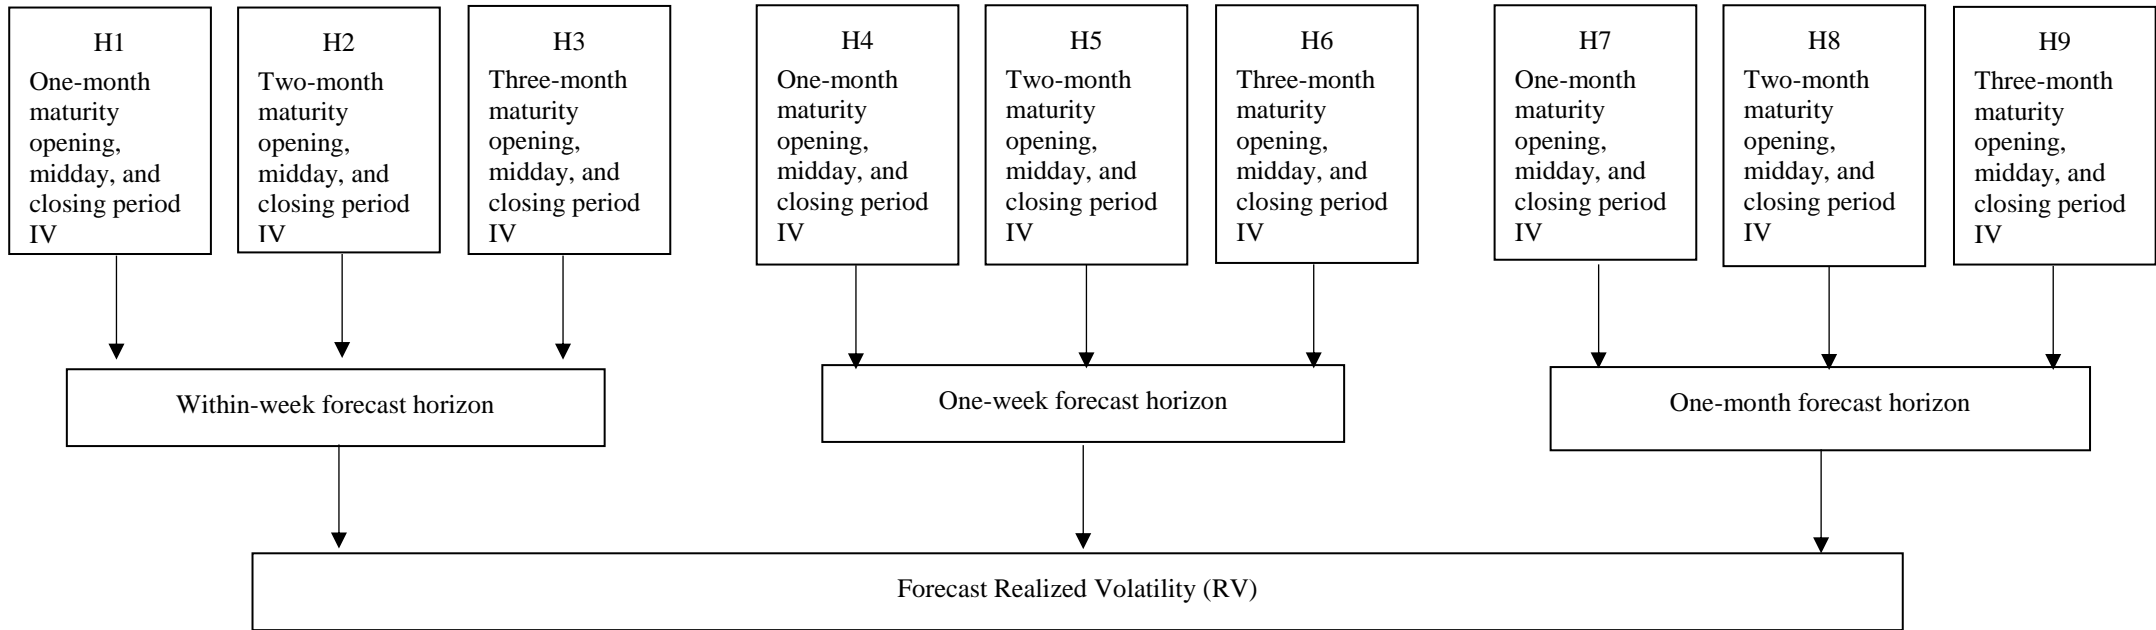

H6: Three-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-week forecast horizon.

H7: One-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-month forecast horizon.

H8: Two-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-month forecast horizon.

H9: Three-month maturity opening, midday, and closing period IV forecast RV of currency accurately for the one-month forecast horizon.

Figure 1. 1: Hypothesis schema for research objective one

For research objective two (Figure 1.2):

H10: One-month maturity opening, midday, and closing period IV estimate currency options price accurately for the within-week estimate horizon.

H11: Two-month maturity opening, midday, and closing period IV estimate currency options price accurately for the within-week estimate horizon.

H12: Three-month maturity opening, midday, and closing period IV estimate currency options price accurately for the within-week estimate horizon.

H13: One-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-week estimate horizon.

H14: Two-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-week estimate horizon.

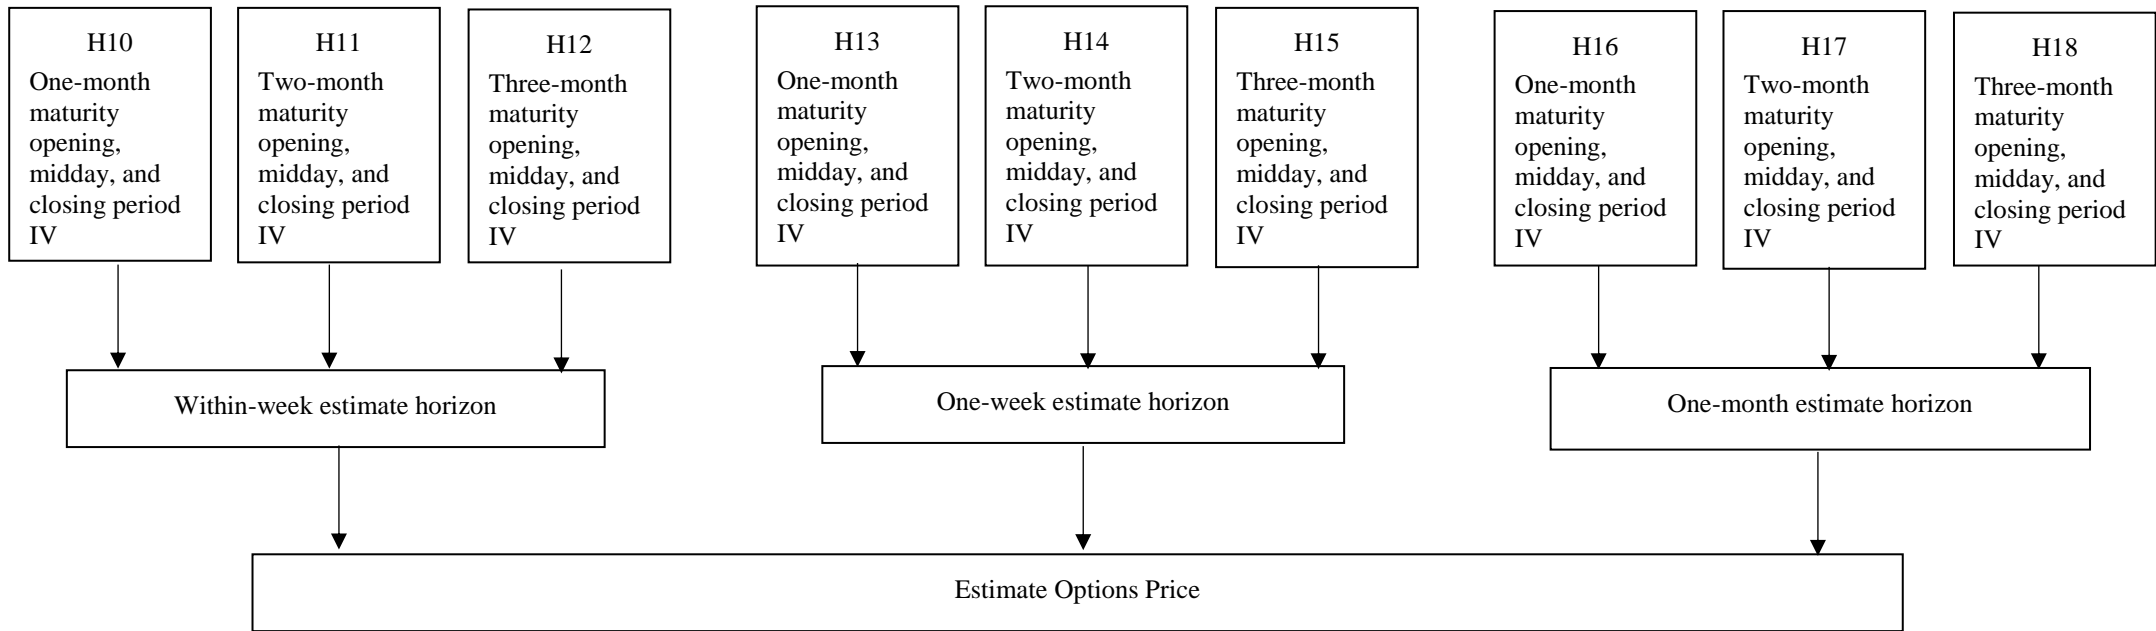

H15: Three-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-week estimate horizon.

H16: One-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-month estimate horizon.

H17: Two-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-month estimate horizon.

H18: Three-month maturity opening, midday, and closing period IV estimate currency options price accurately for the one-month estimate horizon.

1.5 Thesis structure

This thesis comprises six (6) chapters. Chapter 2 summaries the literature, chapter 3 describes the methodology and data, chapter 4 analysis the performance of IV for forecasting the volatility of underlying currency of options, chapter 5 evaluates the performance of IV for pricing currency options, and chapter 6 concludes the thesis including research significance, limitations, and recommendations for future research.

Chapter 2 reviews the performance of implied volatility (IV) in forecasting volatility and pricing options in different markets in the existing literature. This study involves a rigorous literature review on four areas to identify the research gaps and discover the potential of intraday IV to forecast volatility of foreign exchange and pricing currency options. The literature review focuses on four areas (i) the performance of IV to forecast volatility of the stock, stock index, and currency market, (ii) the realized volatility is appropriate to use as a proxy for the actual volatility, and (iii) biasedness of the options pricing model.

Chapter 3 discusses the methodology to test the eighteen (18) hypotheses. For hypotheses 01 to 09, the methods (i) estimate the IV based on the ATM price of call and put options, (ii) estimate the RV for the underlying currency of options, and (iii) analyse the performance of IV to forecast RV. For hypotheses 10 to 18, the procedures (i) calculate the call options model price (CMOD) and put options model price (PMOD) using the ATM estimated IV as input for the options pricing model, and (ii) compare the CMOD and PMOD with the call and put options market price, respectively. Chapter 3 also describes the details of the data used in this study.

Chapter 4 performs an empirical analysis of intraday IV to forecast the RV for testing hypotheses 01 to 09. The analysis conducts in three steps. First, calculate the IV based on the ATM price of currency options with one-month, two-month, and three-month maturity during the opening, midday, and closing period. Second, estimate the RV of the underlying currency of options to use as the proxy for the actual volatility of FX. Third, evaluate the performance of IV in forecasting RV for the within-week, one-week, and one-month forecast horizon.

Chapter 5 conducts an empirical analysis for testing hypotheses 10 to 18 in two steps. First, calculate the call options model price (CMOD) and put options model price (PMOD) using the ATM one-month, two-month, and three-month maturity IV obtained during the opening,

midday, and closing period of a trading day as input for BS options pricing model. Second, generate the options model pricing error by comparing the CMOD and PMOD with the call and put options market price, respectively, to evaluate the performance of IV for pricing currency options accurately, for the within-week, one-week, and one-month estimate horizon.

Chapter 6 discusses the findings from testing eighteen (18) hypotheses. For hypotheses 1 to 9, the empirical findings are based on the performance analysis of IV to forecast RV for the underlying currency of options for the within-week, one-week, and one-month forecast horizon. For hypotheses 10 to 18, the empirical results are based on the performance evaluation of IV to estimate the price of currency options for the within-week, one-week, and one-month estimate horizon. Chapter 6 also covers the discussion on the research significance, research limitations, and recommendations for future research.

CHAPTER 2

Literature Review

2.1 Introduction

This section reviews the performance of implied volatility (IV) in forecasting volatility and pricing options in different markets in the existing literature. This study involves a rigorous literature review to identify the research gaps and discover the potential of intraday IV to forecast volatility of foreign exchange and pricing currency options. First, the literature review focuses on the performance of IV to forecast volatility of the stock, stock index, and currency market. Several empirical studies analyse the performance of only daily IV in forecasting volatility. Therefore, the performance of intraday IV to forecast volatility is one of the critical issues in this study. Second, we examine the literature on the RV to confirm that it is appropriate to use as a proxy for the actual volatility. The appropriateness of RV for an alternative of actual volatility is critical since the performance of intraday IV is evaluated through forecasting RV. Third, this study investigates the literature, and no significant research has been found on the IV for pricing options. However, the IV is widely accepted in the literature that the information content embedded in IV is vital to forecast the volatility of the underlying asset of options. Therefore, a potential research issue that is evaluating the performance of IV to estimate the price of currency options by using it as input for the options pricing model. Fourth, the literature focuses on the biasedness of the options pricing model, which has an impact on the performance of IV for pricing currency options.

2.2 Implied volatility forecasting volatility

The term implied volatility (IV) refers to the volatility of the underlying asset of options in the BS option pricing models (López and Navarro, 2012). It is a widely held view that the IV is computed from the option price observed in the market is a reasonable estimate of the market's opinion of the volatility of the underlying asset. Therefore, the IV is considered as the forward-looking. Early studies that examine the forecastability of IV are equivocal with numerous differences. However, it seems that IV has been found to contain relevant information regarding future volatility, and it often outperforms estimator based on historical data in predicting future realized volatility (RV). Such superior performance appears to be repeated in different types of assets (Andersen et al., 2000).

For individual stock, earlier research such as Latane and Rendleman (1976), Schmalensee and Trippi (1978), Beckers (1981) find that IV provides a better forecast of future volatility than those based on historical data. From a time series perspective, Vasilellis and Meade (1996) and Lamoureux and Lastrapes (1993) find that the volatility forecasts implied by the options market could forecast time-series variations of equity better than predictions produced from time series models. The forecast horizons of this group of papers are around three months to three years. Mayhew and Stivers (2003) examine the information content of IV obtained from the 50 highest options volume companies on the Chicago Board Options Exchange for the period from 1988 to 1995, concerning modeling and predicting the individual firm returns' volatility. The findings indicate that IV consistently surpasses GARCH and incorporates all information contained in return shocks after the first lag for the most active options.

In recent research, Brous et al. (2010) test the accuracy of option IV and four historical volatility measures in predicting future volatility using 10-year daily data for 92 stocks of the S&P 100 Index. Their results show that for larger firms and higher options trading volume firms, IV forecasts are more accurate than historically based forecasts for the forecast interval from 1 day to 33 days. In another study, Garvey and Gallagher (2012) examine the forecastability of IV using a sample of 16 FTSE-100 stocks. Findings from their research indicate that IV on individual UK equities are strictly correlated to RV and provide a useful volatility forecasting method, especially for the medium forecasting horizons that are generated from contracts with maturities between 10 and 30 days.

For the index market, there are significant numbers of papers that use index option IV to predict stock index volatility. Most of these studies focus on S&P100 and S&P500, while the rest forecast index volatility of several smaller stock markets, including FTSE 100 Index, Toronto 35 Index, Spanish IBEX-35 Index, NZX 15 Index, S&P/ASX 200 Index, KOSPI 200 Index and S&P CNX Nifty. Day and Lewis (1992) examine the S&P 100 IV using the daily price of the underlying index from March 1983 to December 1989 and finds that it provides incremental information regarding future volatility compared to the conditional volatility from the GARCH family models. Fleming et al. (1995) find that the average of the S&P 100 option (OEX) implied volatilities (VIX) is a useful instrument for volatility forecasting. Christensen and Prabhala (1998) arrive at a similar conclusion when using the same index at a lower or monthly sampling frequency for the period from 1983 to 1995. Blair et al. (2001) compare the information content of IVs and intraday returns, regards to predicting index volatility over the forecast horizons from 1 to 20 days and find that IV index contains nearly all relevant information about future volatility. The data set in the research include daily S&P100 Index returns and daily IV covering the period from 1987 to 1999. Based on the out-of-sample test, his research indicates that VIX provides the most accurate prediction for 1, 5, 10, and 20 days ahead forecast. Furthermore, Christensen and Hansen (2002) extend the sample used in Christensen and Prabhala (1998) and study IV for the same index for the period from 1993 to 1997. Their findings suggest that IV subsumes valuable information about future movements of volatility, and IV is an efficient forecast of index return volatility. The high predictive ability of VIX has been reported by Gospodinov et al. (2006) and Banerjee et al. (2007).

The superior forecasting performance of IV has also been reported on the non-US market. Gwilym (1999) analyses the data from 21 June 1993 to 19 May 1995 for FTSE 100 index options and conclude that the daily IV contains more information than historical volatilities; however, their evidence suggests that IV is biased. Gwilym (2001) tests the information content of IV in the same context (using daily data of FTSE 100 options during the period from 1993 to 1995) and further supports the idea that IV contains more information compared to historical and GARCH volatility. They show that IV is better than either historical or GARCH based volatility forecasts for horizons ranging from one day to three months. They also find that IV may be a biased representation of market expectations when option prices do not represent the equilibrium market price. Corredor and Santamaria (2004) explore the performance of alternative volatility forecasts for the Spanish IBEX-35 index options using the daily closing prices of this index over the period from 1992 to 1996. Their results are consistent with superior

forecasts produced from IV if compared with historical time series forecasts such as a GARCH model. Noh and Kim (2006) state two different results using two different stock indices, namely the S&P 500 and FTSE 100, for the period from 1994 to 1999. Their findings confirm the inferior performance of IV compared to that of historical volatility for FTSE 100 futures, while for the S&P500, IV outperforms historical volatility in predicting future movement. Frijns et al. (2008) examine the predictive ability of the IV index compiled by NZX 15 Index for the period from September 2005 through May 2006. Their study reveals that IV has predictive power for 66 days ahead forecast of volatility.

In the more current research, another study of Frijns et al. (2010) using daily data on Australian IV Index (AVX) covering the period from 2002 to 2008, conclude that AVX provides essential information for future volatility forecast and it outweighs other commonly used methods such as RiskMetrics and GARCH. Other papers using HSI, KOSPI 200, S&P CNX Nifty, and S&P/ASX 200 report identical conclusion that IV has superior information content than the historical volatility in explaining the stock index volatility (Cheng & Fung, 2012; Ryu, 2012; Shaikh & Padhi, 2014). The superior forecast ability of VIX has been demonstrated in the majority of later research (Ammann et al., 2009; Frijns et al., 2010; Ryu, 2012). Moreover, Cheng and Fung (2012) compare the forecasting performance of model-free IV (MFIV) using different prediction horizons. Their findings conclude that Black-Scholes IV (BSIV) is unbiased for different horizon forecasts from one week to six weeks, and MFIV can beat the time-series forecasts based on historical volatility. They also report the decline in the predictive power of BSIV and MFIV as the forecasting horizon shortens. The volatility forecasting power of IV varies over time, depending on the level of investor sentiment using the data on the S&P 500 from January 1996 to August 2010 (Seo & Kim, 2015). Kourtis et al. (2016) compare the predictive ability and economic value of IV and RV for 13 equity indices from 10 countries at different forecast horizons (one day, five days, and twenty-two days ahead). They show that the forecast ability differs as the forecast horizon changes. The IV model offers a superior forecast at the monthly horizon. However, the method performs significantly worse for the crisis period from 2008-2009. Wang and Wang (2016) examine the information content of intraday IV using the S&P500 Index for the period from 2005 to 2010 and find that the IV around noon contains more useful information regarding future volatility than IV at the market's closing, which has been frequently used in the previous literature. Pati et al. (2018) examine the information content of the IV index in forecasting volatility based on the data sample from the three Asia-Pacific stock markets consisting of India, Australia, and Hong

Kong covering the period from Jan 2008 to July 2016. They use RV based on five-minute frequency data as the proxy for the latent volatility and conclude that the IV index contains incremental information in explaining future RV. The identical conclusion about superior informative content of IV compared to RV for S&P 500, the FTSE 100, and the Chinese 50 Exchange-Traded Funds is found in the research of Shi et al. (2019).

Another strand of research has focused on examining the dynamics of IV. Using the S&P 100 index option to examine the dynamic behavior of market volatility, Harvey and Whaley (1992) suggest that IV changes can be predicted ahead of time. Their study also indicates that IV tends to fall on Fridays and rise on Mondays. Using CBOE Market Volatility Index (VIX), an average of S&P 100 option, Fleming et al. (1995), however, reject the inter-week seasonality. Furthermore, this study indicates that VIX is inversely related to the contemporaneous S&P 100 index return and that both daily and weekly VIX changes are more sensitive to the negative shock than the positive shock in the market. Simon (1997) also reports similar IV asymmetries for treasury bonds and futures options. Ederington and Lee (1996), however, show that the IV in the treasury bonds and Eurodollar options on futures markets tend to decline on the days with scheduled announcements as the uncertainty regarding the impact of the announcement on security prices is resolved. Besides that, Hann et al. (2019) confirm a reasonably positive association between changes in the IV of each industry's first announcer and its peers around the first announcers' earning announcement.

For currency options, in the earlier research, Scott and Tucker (1989) analyse the predictive power of IV using options data for GBP, CAD, Deutsche mark (DEM), Japanese Yen (JPY), and CHF against the USD. They find that IV forecasts efficiently for up to six to nine months horizon, captures nearly 50 percent of actual currency volatility. However, when historical volatility is included in the investor's information set, they find no evidence of improved predictive accuracy. Xu and Taylor (1994) examine the informational efficiency of the currency options market in the Philadelphia Stock Exchange. They study four currencies (GBP, DEM, JPY, and CHF against the USD) over the period from January 1985 to January 1992. They find that option prices contain useful information about future volatilities. Jorion (1995) examines the forecasting power of IV for DEM, JPY, and CHF against the USD, traded on the CME. The results suggest that IV outperforms statistical time-series models regarding information content and predictive power but appears to be upward biased estimators of future volatility. Similarly, Kazantzis and Tassaromatis (2001) examine the information content and

predictive power of IV using six currencies (JPY, DEM, GBP, CHF, CAD, and AUD against the USD) for the period from December 1989 to April 1997. These authors report that although IV has more information content than approaches based only on historical or GARCH based volatilities for horizons ranging from one day to three months, it is also a biased predictor of future volatility for at least some of the currencies in the sample.

Covrig and Low (2003) use OTC data for USD per GBP, JPY per USD, and USD per AUD to examine the information of IV for different forecast horizons. They suggest that quoted IV subsumes the information content of historically based forecasts at shorter horizons (one-month and two-month horizon), and the former is as good as the latter at longer horizons (three-month and six-month horizon). Kim and Kim (2003) show that the IV of the CAD, CHF, DEM, GBP, and JPY options tends to be low in the early part of the week but remains high in the last part of the week beginning on Wednesdays. Pong et al. (2004) find that the IV of the DEM, GBP, and JPY options that incorporate most of the relevant information for the forecast horizon is either one-month or three-month. Christoffersen and Mazzotta (2005) show that the IV of ATM options for the EUR, GBP, and JPY provide mostly unbiased and reasonably accurate forecasts of one-month and three-month ahead of actual volatility. Chang and Tabak (2007) produce evidence that the IV of Brazilian real options contain significant information that is missing in the econometric models, and it provides superior FX forecasts.

In the more current research, Busch et al. (2011) test the role of IV in forecasting future volatility using data from three markets, including foreign exchange, stock, and bond markets. They identify that for all investigated markets, IV subsumes helpful information for volatility forecasting, and it provides an unbiased prediction in the foreign exchange and stock markets. Marshall et al. (2012) show that the IV of ATM options of CHF, EUR, GBP, and JPY tends to drop on the announcement day; moreover, the impact that positive news has on this is generally the same as the impact from negative news. Mwamba and Majadibodu (2012) examine the leading indicator for currency crisis identification using data on the South African rand against the US dollar and find that IV of foreign exchange options offers an early signal of the crisis before it occurs. Pilbeam and Langeland (2015) confirm that the IV of CHF, EUR, GBP, and JPY forecasts significantly outperform the GARCH model in both the low and high volatility periods of the FX market. Wong and Heaney (2017) find the knowledge of the volatility smile implied from foreign exchange options improves foreign exchange volatility forecast accuracy using options with one-month to maturity written on four exchange rate series, GBP/USD,

EUR/USD, AUD/USD, and the USD/JPY from 2001 to 2006. IV continues to be reported as a biased measure of actual volatility, but it outperforms historical volatilities in forecasting future RV in the research of Sahoo and Trivedi (2018). Their study employs the non-overlapping monthly volatility data of USD/Indian Rupee and finds that IV contains all the information content of historical volatility about future RV.

2.3 Realized volatility

Until the late 1970s, using monthly data played an essential role in empirical research due to the unavailability of and access problems to lower frequency, such as daily or intraday data. However, the development of information technology in the 1990s provides access to time-stamped observations on all quotes and transactions. These tick-by-tick data, termed as ultra-high-frequency data by Engle (2000), are usually referred to as high-frequency data in current studies. The availability of high-frequency data is vital for constructing an adequate framework for estimating and forecasting the conditional variance of financial assets returns. Although the high-frequency data provides more accurate measurement and prediction of future volatility, it also leads to microstructure noises that can arise through the bid-ask bounce, asynchronous trading, infrequent trading, and price discreteness, among other factors (McAleer & Medeiros, 2008).

In many financial applications, the asset price is assumed to follow a continuous-time diffusion process. That means the daily volatility can be calculated by integrating the volatility during the day, named integrated volatility. If the discretely sampled returns are serially uncorrelated, and the sample path of the volatility process is continuous, it follows the theory of quadratic variation. Further, given the Brownian motion, the quadratic variation might be found in asset returns (Baxter & Rennie, 1996). The quadratic variation process, therefore, measures the realized sample-path variation of the squared return process. The sum of intraday squared returns under the quadratic variation process is defined as RV.

The inherent nature of high-frequency data is that they are composed of the random daily number of time-series observations with random arrival times. This feature of the high-frequency data presents a problem concerning organising the data for empirical work. Engle and Russell (1998) and Engle (2000) propose an Autoregressive Conditional Duration Model for the irregular intervals data. The time aggregated data at minute sampling intervals can be used to avoid the time series modeling complications of high-frequency data. Although this aggregation up to fixed intervals of time may lead to loss of information, it is easy to implement and widely adopted in the current empirical analysis of asset pricing models that use high-frequency data. The data sampling frequency should be specific to the underlying asset because the trading intensity and price discovery are different across assets. Andersen et al. (2000, 2001a, 2003) propose a possible solution to reduce the microstructure bias by sampling the

returns at arbitrarily selected lower frequencies like five or fifteen minutes. Merton (1981) and Nelson (1991) argue that the precise estimation of volatility can be obtained from an arbitrarily short span of data provided that returns are sampled sufficiently frequently. Identically, Aït-Sahalia et al. (2005) report that sampling as frequently as possible would theoretically produce in the limit a perfect estimate of RV. With available high-frequency data, it is possible to obtain considerable improvements in measuring return volatility. These theoretical promises have been justified by the empirical research with high-frequency returns, especially after the introduction of the emerging RV concept by Andersen et al. (2001a).

A vast number of current researches apply this method and use five-minute returns to measure the RV and test its properties from different perspectives. Andersen et al. (2001a) use 30 individual Dow Jones Industrial Average (DJIA) stocks for the period from 1993 to 1998 to test the RV and find that the distribution of stock returns scaled by the realized standard deviations are also approximately Gaussian, as are the distributions of the realized logarithmic standard deviations and correlations. Moreover, volatilities and correlations move together, show strong dependence, and can be well described by long-memory processes. Similar conclusions are reported by applying different assets such as FTSE-100 Index futures, Taiwan Stock Exchange (TSE), S&P 500 (Areal & Taylor, 2002; Huang & Nieh, 2004; Thomakos & Wang, 2003). Barndorff-Nielsen and Shephard (2002, 2004) make further progress in the econometric analysis of the RV approach. They study the statistical properties of RV in the context of the stochastic volatility model and obtain the RV asymptotic distribution as well as its rate of convergence.

Huang and Nieh (2004) examine the distributional characteristics of the RV and dynamic correlations using high-frequency (one-minute) intraday stock indices for the TSE from January to December 2000. They find that the critical feature of this RV and correlations is that they are not only model-free but also approximately measurement-error-free. Their finding indicates that these estimated volatilities can be treated as observed rather than latent so that direct modeling and forecasting of RV can be performed using a conventional time-series approach. Chan and Fong (2006) estimate daily volatility using RV obtained by summing up intraday squared returns. They use the sample of the 30 stocks in the Dow Jones Industrial Average Stock Index from 1993 to 2000. Consistent with the theory of quadratic variation, their RV estimates are shown to be less noisy than standard volatility measures, such as absolute returns used in their previous study. Zhang and Hu (2013) investigate the information

content of RV using the data of the Chinese stock market from 2004 to 2009. The empirical analysis shows that RV can provide additional information in the volatility process for some stocks, but a similar conclusion cannot be drawn in some other stocks. The best time interval to construct RV measures is the 30 minutes interval. Likewise, Pooter et al. (2008) conclude that the optimal sampling frequency ranges are from 30 minutes to 65 minutes, significantly lower than the five-minute frequency when testing the S&P 100 index constituents and S&P 500 index futures for the period from 1997 to 2004. In another paper, Degiannakis and Floros (2016) construct measures of intraday RV for 17 European and USA stock indices and suggest that the intraday adjusted RV reduces the underestimation of the actual variability sharply.

Taylor and Xu (1997) estimate the RV at the hourly and daily level for five-minute returns of DEM/USD quotations from 1992 to 1993 to construct the conditional variances of hourly and daily returns, respectively. The findings show that a significant amount of information in five-minute returns can be found in the hourly conditional variances than that of daily conditional variances. A number of studies use five-minute returns to estimate the RV and examine its properties from different perspectives. Andersen et al. (2000) consider the unconditional and conditional distribution of the exchange rate volatilities and correlations, and find that the exchange rate returns standardized by RV are nearly Gaussian, and the realized variance tends to be log-normally distributed. Andersen et al. (2001b) derive the theoretical and empirical properties of RV for the DEM/USD and JPY/USD exchange rates based on the earlier work of Taylor and Xu (1997) for the period from 1986 to 1996. They find that the volatility movements are highly correlated across the two exchange rates, and the correlation between the exchange rates increases with volatility. Barndorff – Nielsen, and Shephard (2002) examine the statistical properties of RV in the context of the stochastic volatility model. They employ the dataset of a five-minute USD/DEM exchange rate from 1986 to 1996, and their results provide both a central limit theory approximation as well as an exact second-order analysis. The authors introduce the simple way of formally bridging the gap between realized and actual volatility. Liu et al. (2015) examine the accuracy of RV constructed from high-frequency of a variety of assets and compare them with a realized variance estimator. They consider the total of 400 different estimators for 31 different financial assets spanning five asset classes (US equities, UK equities, FX futures, bond futures, and Index futures) covering 11 years. The findings show that the five-minute RV as the benchmark can be outperformed other measures, and it is challenging to beat five-minute RV significantly.

2.4 Options pricing model

This section discusses the accuracy of the pricing model. Several papers focus on the futures pricing models for stock index futures (Becker et al., 2009; Dupoyet et al., 2011; Psychoyios et al., 2010; Zhang & Zhu, 2006; Zhongjin & Yingzi, 2010). Whereas, another trend of research concentrates on IV is the development of model-free implied volatility (MFIV), proposed by Britten-Jones and Neuberger (2000) and Car and Madan (1998). Instead of depending on any option pricing formula, MFIV uses options prices from the full range of available strike prices. Thus, the MFIV avoids the drawbacks of the BS option pricing model, such as the assumption of constant volatility. Although MFIV is reported to contain all information for future volatility obtained in BSIV and historical volatility and provides an efficient prediction of future volatility in some articles (Biktimirov & Wang, 2011; Jiang & Tian, 2005). The majority of studies using index options data and option prices on individual stocks find that BSIV outperforms MFIV in forecasting the future RV (Andersen et al., 2007; Cheng & Fung, 2012; Muzzioli, 2010; Taylor et al., 2010).

Biktimirov and Wang (2017) compare the performance of BSIV with MFIV in predicting volatility using the data from 13 North American, European, and Asian stock market indexes. The findings indicate the dominance of BSIV to MFIV for predicting future volatility, and BSIV provides more accurate volatility forecasting for a one-month forecast horizon than MFIV and GJR-GARCH volatility. Harikumar et al. (2004) compare the performance of the BS model and GARCH option pricing models in estimating call option prices for the foreign exchange market. The closed-form model options price is generated for the BS volatility model, and the empirical martingale simulation is used as the options pricing model for the GARCH models. The dataset used in the study includes data on call options of three currencies (GBP, JPY, and CHF) for the period from 1987 to 1996. The results show that the BS model performs more accurately than the GARCH model in options pricing. Baldeaux et al. (2015) construct a stochastic volatility model that recovers the typically observed IV smiles and skews for short-dated vanilla foreign exchange options and allow to price payoffs in foreign currencies, lower than possible under the standard risk-neutral pricing for long-dated derivatives.

Similarly, Lian et al. (2016) introduce a stochastic volatility model for pricing FX derivatives, which is consistent with stylized facts (smiles, skews, and symmetries) of the FX market. The

authors extend the Esscher transform technique to obtain analytical pricing formulas based on solving a system of Markov-modulated Esscher parameters.

2.5 Conclusion

This chapter discusses literature and evidence related to the performance of IV in forecasting volatility as well as options price. Various papers are testing the forecasting power of IV. The predictive ability testing focuses mainly on the leading stock indices and foreign exchange rates. For stock and stock indexes, numerical analyses report that IVs provide a better forecast of future volatility than those based on historical data, but they are biased (Beckers, 1981; Cheng & Fung, 2012; Latane & Rendleman, 1976; Ryu, 2012; Schmalensee & Trippi, 1978; Shaikh & Padhi, 2014). Moreover, IV provides better forecasts at the monthly horizon. For the foreign exchange market, IV is proved to provide incremental information about a future variance for short horizons up to three months (Covrig & Low, 2003). IV incorporates most of the relevant information and holds superior predictive power for the FX market (Busch et al., 2011). IV tends to be low and high in the early and later of the week, respectively (Kim & Kim, 2003). IV of ATM options provide mostly unbiased and relatively accurate forecasts of one-month and three-month ahead of actual volatility (Christoffersen & Mazzotta, 2005). Overall, the literature has not provided a clear explanation to the question of practitioners that which measure of volatility can estimate and forecast volatility accurately.

The availability of high-frequency data is increasing; the research attention has shifted towards a model that employs intraday data in estimating and forecasting daily volatility. Most of the research finds the importance of intraday data in improving volatility predicting. There is a significant amount of information in the five-minute returns when estimating hourly variances. The first hours of the trading day contain more relevant information about the volatility observed at the end of the trading day, and the additional use of intraday data today to forecast volatility on the following day is most advantageous when the following day is a low volume or an up-market day. So far, there are not many pieces of research utilising the high-frequency data in estimating and forecasting IV. The variety in the information content of IV at different intraday levels has been confirmed in the research of Wang and Wang (2016). Their findings indicate that VIX around noon is most informative for forecasting RV. In terms of the FX market, all the previous literature in IV has concluded that the relevant information for predicting the volatility of an underlying asset can be found in the options price. However, concentrating on FX volatility indicates that IV contains the discrete information regarding the FX movement at a specific time of the trading day. Therefore, daily IV is not sufficient for estimating FX volatility accurately. Most of the studies for currency options employ the closing

price that can not subsume all the information of volatility for the whole trading period. It leads to the question that the IV of which period (opening, midday, or closing) of a trading day can provide the most incremental information for forecasting volatility and estimating options price.

The RV is most widely used proxy for actual volatility in the previous literature is the daily squared return. Nevertheless, the increasing availability of high-frequency data has led to a significant improvement in measuring volatility (Pati et al., 2018). As the daily squared return is considered as the noisy proxy for the actual volatility, the RV calculated from high-frequency intraday returns is a better choice for the actual volatility. The use of a five-minute interval is the most common and widely used in the literature (Andersen et al., 2003), and it is challenging to beat the five-minute RV (Liu et al., 2015). The five-minute interval is found to maintain not only the right balance between very-low-frequency observation but also robustness to market microstructure effect that rises from using too short-time intervals.

CHAPTER 3

Methodology and Data

3.1 Introduction

This chapter first discusses the methodology to test the eighteen (18) hypotheses that have been developed in chapter 1. For hypothesis 01 to hypothesis 09, the methods are used to (i) estimate the IV based on the ATM price of call and put options with one-month, two-month, and three-month maturity during the opening, midday, and closing period of a trading day, (ii) estimate the RV for the underlying currency of options and using it as the proxy for the actual foreign exchange volatility, and (iii) analyse the performance of IV to forecast RV for the within-week, one-week, and one-month forecast horizon. For hypothesis 10 to hypothesis 18, the procedures are employed to (i) calculate the call options model price (CMOD) and put options model price (PMOD) using the ATM estimated IV as input for the options pricing model, and (ii) compare the CMOD and PMOD with the call and put options market price, respectively, evaluating the performance of IV to estimate the price of currency options for the within-week, one-week, and one-month estimate horizon. Finally, the details of the data are described in this chapter.

3.2 Implied volatility estimation

The IV refers to the volatility of the return of the asset underlying an option in an option pricing model. Under the BS model, the log return of the underlying asset price from the present time up to the expiration date of the option is assumed to follow a normal distribution. When all the variables involved in the option valuation (the stock price, the strike price, the risk-free rate, and the time to maturity) can be directly observed, by equating the market price of the option to its model value, one recovers the IV over the life of the option. Therefore, the IV is considered to be a forward-looking volatility estimate.

The use of an inappropriate option valuation model will lead to mismeasurements in the IV. For example, if the options are American, but the European model is applied to calculate that options IV, then the error will be caused by the neglect of the early exercise option. Other biases may be due to the different closing times of stock and options markets (Blair et al., 2001). The BS model has been using widely in the literature (Corredor & Santamaria, 2016) for pricing European options. Ease of calculation, as well as theoretical approximations between stochastic volatility and conditional volatility models to BS for ATM options and nearest to expiration (Fleming, 1998; Nelson, 1990), are some of the reasons for its widespread application.

Further, Biktimirov and Wang (2017) demonstrate the outperformance of IV obtaining through the BS model over the model-free IV in predicting future volatility from both developed and emerging index options markets. Merton (1973) extended the BS model for continuous dividends. As the interest gained on holding foreign currency is equivalent to a continuously paid dividend on a stock, the Merton version of the BS (BSM) model employs for the foreign currency options where FX rate replaces the stock price. The notation of the BSM model and its' descriptions are as follows:

C_t = call options price in domestic currency at time t

P_t = put option price in domestic currency at time t

S_t = spot rate at time t

X_t = exercise price in domestic currency at time t

R_t^d = domestic currency interest rate at time t

R_t^f = foreign currency interest rate at time t

T = options expiration time

σ_t = volatility of underlying currency

N = Cumulative normal distribution function

In BSM model, the European type call and put options are priced as,

$$C_t = S_t e^{-R_t^f T} N(d_{1,t}) - X_t e^{-R_t^d T} N(d_{2,t}), \quad (3.1)$$

$$P_t = X_t e^{-R_t^d T} N(-d_{2,t}) - S_t e^{-R_t^f T} N(-d_{1,t}), \quad (3.2)$$

$$d_{1,t} = \frac{\ln\left(\frac{S_t}{X_t}\right) + \left(R_t^d - R_t^f + \frac{\sigma_t^2}{2}\right)T}{\sigma_t \sqrt{T}} \quad \text{and}$$

$$d_{2,t} = \frac{\ln\left(\frac{S_t}{X_t}\right) + \left(R_t^d - R_t^f - \frac{\sigma_t^2}{2}\right)T}{\sigma_t \sqrt{T}} = d_{1,t} - \sigma_t \sqrt{T}.$$

For notations convenience, let $\xi_t = e^{-R_t^f T}$ and $\eta_t = e^{-R_t^d T}$ so that equations (3.1) and (3.2) can be written as follows:

$$C_t = S_t \xi_t N[d_{1,t}(\sigma_t)] - X_t \eta_t N[d_{2,t}(\sigma_t)], \quad (3.3)$$

$$P_t = X_t \eta_t N[-d_{2,t}(\sigma_t)] - S_t \xi_t N[-d_{1,t}(\sigma_t)]. \quad (3.4)$$

The C_t and P_t is substituted with call options market price (C_t^{MKT}) and put options market price (P_t^{MKT}) as in equation (3.5) and equation (3.6), respectively.

$$C_t^{MKT} = S_t \xi_t N[d_{1,t}(\sigma_{c,t}^{k,l})] - X_t \eta_t N[d_{2,t}(\sigma_{c,t}^{k,l})] \quad (3.5)$$

$$P_t^{MKT} = X_t \eta_t N[-d_{2,t}(\sigma_{p,t}^{k,l})] - S_t \xi_t N[-d_{1,t}(\sigma_{p,t}^{k,l})] \quad (3.6)$$

Now the equation (3.5) and equation (3.6) provides the IV for call options market price ($\sigma_{c,t}^{k,l}$) and IV for put options market price ($\sigma_{p,t}^{k,l}$), respectively, through an iterative search procedure, where \forall_k = one-month, two-month, and three-month maturity options; \forall_l = opening, midday, and closing period of a trading day.

It is not possible to invert equation (3.5) and (3.6) with respect to the $(\sigma_{c,t}^{k,l})$ and $(\sigma_{p,t}^{k,l})$, respectively. Alternatively, an iterative search procedure can be used to identify the IV for the given options market prices. The two most popular approaches in the literature are the Newton-Raphson and Dekker-Brent method, respectively (Press et al., 1992). The Dekker-Brent method refers to a blend of the bisection, secant and inverse quadratic interpolation methods, and convergence assured. The Newton-Raphson method is faster in processing, but it is less robust in comparison with the Dekker-Brent method. Both methods work very well for a single option and produce a significantly accurate estimate of IV in negligible computing time (Li, 2008). The Newton-Raphson method is at risk of machine failure due to an inappropriate division by a small number, or it might send the next iteration out of a bracketed region. However, this study utilises a relatively simple function of the volatility for option prices; it is, therefore, possible to use the Newton-Raphson approach.

Despite numerous weighted-average techniques for calculating IV have been suggested, there is no theoretically appropriate weighting scheme in the literature to estimate IV. Jorion (1995) computes IV as the average of the call options price IV and the put options price IV. Furthermore, Hull (2014) suggests that, for a given strike price and maturity, the correct volatility to use in conjunction with the BS model to price a European call should always be the same as that used to price a European put. To implement this idea for equations (3.5) and (3.6), this present study estimates IV as:

$$\hat{\sigma}_t^{k,l} = \frac{\hat{\sigma}_{c,t}^{k,l} + \hat{\sigma}_{p,t}^{k,l}}{2} \quad (3.7)$$

3.3 Realized volatility estimation

The actual volatility is unobservable, so in evaluating volatility estimating and forecasting, the usual proxy for ‘true volatility’ is the so-called realized variance. This is calculated by the sum of squared intraday returns sampled at the equally spaced interval (Andersen & Bollerslev, 1998; Barndorff-Nielsen & Shephard, 2002). Particularly, the quadratic variation theory indicates that the realized variance asymptotically converges to the actual unobserved variance as the sampling frequency increased to infinity (Barndorff-Nielsen & Shephard, 2002). The RV is constructed by summing the squared intraday returns sampled at a particular frequency. The optimal frequency for constructing RV is unknown. Following the standard practice and previous literature, there is litter evidence that the five-minute RV as the benchmark can be outperformed by any other measures, and it is difficult to significantly beat five-minute RV (Liu et al., 2015). Thus, this study uses daily RV series constructed from five-minute intraday transaction prices as a proxy for the unobservable variance. If S_i is the exchange rate for 5 minutes sampling frequency, the underlying exchange rate return in 5 minutes interval is estimated as

$$r_{i,t} = \ln\left(\frac{S_i}{S_{i-1}}\right), \quad (3.8)$$

where $r_{i,t}$ is the return in interval i on day t . The realized variance of day t is computed as

$$v_t = \sum_{i=1}^n r_{i,t}^2, \quad (3.9)$$

where n is the total number of intervals for the options trading hour from 9:30 to 16:00 of trading days Monday to Friday. Since RV is the standard deviation of the realized variance, the RV per trading day is

$$\hat{\sigma}_t^{RV} = \sqrt{v_t}. \quad (3.10)$$

As intraday data of trading days are used to provide RV estimate, days when the exchange is closed are ignored and the RV per annum is,

$$\hat{\sigma}_t^{RV} = \sqrt{Dv_t}, \quad (3.11)$$

where, D is 252 trading days per year consistent with the normal assumption of options market.

3.4 Implied volatility forecasting realized volatility

This section discusses the methodology to assess the performance of IV in forecasting RV. For each IV obtained from different maturity of options, the forecasting evaluation is implemented using the regression test that is introduced by Mincer and Zarnowitz (1969), namely Mincer-Zarnowitz (MZ) regression. In the MZ regression, the RV is regressed on a constant and IV as in equation (3.12),

$$RV_{t+i}^m = \beta_0 + \beta_1 \hat{\sigma}_t^{k,l} + \varepsilon_t, \quad (3.12)$$

where \forall_m = within-week, one-week, and one-month forecast horizon.

The MZ regression allows evaluating two different aspects of the volatility forecast. First, the unbiasedness and efficiency of the forecast are evaluated by testing the intercept and slope through the joint hypothesis ($H_0: \beta_0 = 0$ and $\beta_1 = 1$) (Guler et al., 2017). Second, the accuracy of the forecast is evaluated by the high goodness of fit value, R-squared (R^2). The R^2 is a statistical measure that represents the percentage of the variance for RV explained by IV. The R^2 is used to compare the capability of IV to forecast RV for different situations. For example, the R^2 of IV for the one-week forecast horizon is higher than that of the one-month forecast horizon. It indicates that the RV can be explained well by the IV for the one-week forecast horizon, that is, IV outperform to forecast RV for the one-week forecast horizon than the one-month forecast horizon. The MZ regression is estimated using the OLS (ordinary least squared) method with Newey-West corrected errors for heteroscedasticity and serial correlation. As the variance of the innovation term ε_t in equation (3.12) depends on the accuracy of the volatility proxy, the higher quality the proxy is, the more accurately the regression parameters are estimated. Moreover, the R^2 - in (3.12) is also penalised if the quality of the proxy decreases.

3.5 Implied volatility estimating options model price

This section provides the method to estimate the currency options model price. The CMOD and PMOD is calculated using the ATM estimated IV as input for the BSM options pricing model. The C_t^{MKT} and P_t^{MKT} in equation (3.5) and equation (3.6), respectively, is substituted with call options estimated model price ($\hat{\Pi}_{c,t}^{MOD}$) and put options estimated model price ($\hat{\Pi}_{p,t}^{MOD}$) as in equation (3.13) and equation (3.14), respectively.

$$\hat{\Pi}_{c,t}^{MOD} = S_t \xi_t N[d_{1,t}(\hat{\sigma}_{t-i}^{k,l})] - X_t \eta_t N[d_{2,t}(\hat{\sigma}_{t-i}^{k,l})] \quad (3.13)$$

$$\hat{\Pi}_{p,t}^{MOD} = X_t \eta_t N[-d_{2,t}(\hat{\sigma}_{t-i}^{k,l})] - S_t \xi_t N[-d_{1,t}(\hat{\sigma}_{t-i}^{k,l})] \quad (3.14)$$

where $\forall_i =$ within-week, one-week, and one-month estimate horizon. The within-week estimate horizon indicates that the IV is estimated one day to four days before the date of pricing currency options. Similarly, the one-week and one-month estimate horizon imply that the IV is estimated one-week and one-month before the date of pricing currency options, respectively. In equations (3.13) and (3.14), $i > 0$ to estimate the call options model price ($\hat{\Pi}_{c,t}^{MOD}$) and put options model price ($\hat{\Pi}_{p,t}^{MOD}$) based on the ATM estimated IV at the time $t-i$ ($\hat{\sigma}_{t-i}^{k,l}$) using equation (3.7).

3.6 Options pricing error estimation

The options pricing error (OPE) estimation methodology is developed in this section. The OPE is computed as the difference between the observed ATM options market price and the estimated options model price. The OPE is generated using standard statistical accuracy criteria, such as mean absolute error (MAE), mean squared error (MSE), and the root mean squared error (RMSE). If $\Pi_{j,t}^{ATM}$ and $\hat{\Pi}_{j,t}^{MOD}$ represent the ATM options market price and estimated options model price, respectively, the OPE is generated for a number of observations under MSE, MAE and MAPE measures as follows, respectively,

$$MAE^{m,l} = \frac{1}{n} \sum_{t=1}^n |\Pi_{j,t}^{ATM} - \hat{\Pi}_{j,t}^{MOD}| \quad (3.15)$$

$$MSE^{m,l} = \frac{1}{n} \sum_{t=1}^n (\Pi_{j,t}^{ATM} - \hat{\Pi}_{j,t}^{MOD})^2 \quad (3.16)$$

$$RMSE^{m,l} = \sqrt{\frac{1}{n} \sum_{t=1}^n (\Pi_{j,t}^{ATM} - \hat{\Pi}_{j,t}^{MOD})^2} \quad (3.17)$$

For $\forall j = c$ (call price) and p (put price).

MSE, RMSE, and MAE are three of the most popular measures of the accuracy of the minimum pricing error estimation. While the MSE and RMSE metrics are appropriate if the loss function used in the estimator's decision-making process is that of the symmetric mean square error, the MAE is suitable to the loss function that is the symmetric mean absolute error. The MAE approach does not permit the offsetting effect of over- and under-prediction (Kambouroudis et al., 2016). Although there are some valid concerns over using RMSE raised by Willmott et al. (2005), the RMSE is considered to be more appropriate to assess the model performance than the MAE when the error distribution is Gaussian. It is reported that an estimation that is considered as good using one measure might not be the same according to another measure (Elliott & Timmermann, 2008). However, the combination of metrics, including but not limited to RMSE and MAE, are necessary to evaluate model performance (Chai & Draxler, 2014).

3.7 Data description

This study uses the intraday data for AUD, CAD, CHF, EUR, and GBP European currency options provided by the Options Price Reporting Authority (OPRA) as the last-sale options quotations. The OPRA reports prices on US equity, index, currency, and interest rate options from the following exchanges: AMEX, Boston, Chicago, ISE, Pacific, and Philadelphia. These data are obtained from Thomson Reuter's database through Securities Industry Research Centre of Asia-Pacific (SIRCA), that provides global intraday trade and quote information for over 240 markets around the world with data coverage beginning from January 1996 for an extensive range of equities, indices, foreign exchange, money, fixed income, and derivative instruments. The Reuters Instruments Code (RIC) is employed to extract European options data from Reuter's database through the options ticker symbols XDA, XDC, XDS, XDE, and XDB for AUD, CAD, CHF, EUR, and GBP, respectively. The sample period begins on 01 January 2010 and ends on 31 December 2017 for all currencies.

The options are traded on Monday to Friday, excluding public holidays from 9:30 to 16:00 (US Eastern standard time), and expire on the third Friday of each month. The contract size of five sample currency options is AUD10,000, CAD10,000, CHF10,000, EUR10,000, and GBP 10,000, and settle in US dollar. The time to maturity of an option is assumed to be the number of calendar days remaining until the option matures. The option with the time to maturity ranging from 2 days to less than or equal to 30 days is considered to be a one-month maturity option. The two-month maturity options include those that have time to maturity is between 31 days to less than or equal to 60 days. The options that have time to maturity covering from 61 days to 90 days are considered to be the three-month maturity options. All sample currency options are used to construct the intraday IV for the opening period (9:30 to 10:00), midday period (12:30 to 13:00), and closing period (15:30 to 16:00) of the trading day. Each of these trading periods is selected for half an hour slot in order to position them evenly in a six and half hours trading day from 9:30 to 16:00. It means the time difference between 'opening period' and 'midday period' and between 'midday period' and 'closing period' is equal (i.e., two and half hours).

In this study, the ATM put-call pairs used to obtain unbiased IV through the BSM options pricing model. The BSM model assumes the volatility is constant, which introduces bias into the IV estimation. Hull and White (1987) stated that the magnitude of the bias in the BS model

was the smallest for near-the-money and close-to-maturity options. Therefore, the IV is calculated based on the ATM one-month, two-month, and three-month maturity options traded during the opening, midday, and closing period of a trading day. To distinguish ATM options, we follow the criteria in Xing et al. (2010). That is, call and put options are considered as ATM when the ratio of the strike price to the stock price is between 0.995 and 1.005. The midpoint of the close bid/ask quote of each five-minute interval computes each options price to mitigate problems due to bid/ask bounce (Blair et al., 2001). The for one-month, two-month, and three-month USD deposit interest rate use as the risk-free interest rate in the BSM model for all currency options at the corresponding maturity. The continuous dividend yield for the currency options is equal to the foreign currency deposit interest rate. The reason is that holding a foreign currency that pays interest in the foreign currency at the foreign deposit interest rate, which reinvests in the foreign currency continuously, is similar to holding stock paying a continuous dividend, which reinvests in the additional units of the stock.

This study tests the eighteen (18) hypotheses to achieve the aim of the research. Therefore, it selects the ATM put-call pair (PCP) obtained for the same trading date, trading time, expiration date, expiration time, and strike price as the first step for testing the hypothesis. Tables 3.1 to 3.6 show the details of PCP for all hypotheses. The number of PCPs and the number of trading days is analogous. Table 3.1 describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 1, 2, and 3, respectively. Panels A, B, and C present the PCPs of each currency for the within-week forecast horizon (Mon-Fri, Tue-Fri, Wed-Fri, and Thu-Fri) during the opening, midday, and closing period of a trading day, respectively.

For one-month maturity IV (hypothesis 1), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A4.1a in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 1. For example, the one-month maturity opening period IV_AUD (0.1689) in column 13 is computed employing the PCP pair on 21-Jun-10 (Monday) to forecast the RV_AUD (0.0989) in the last column on 25-Jun-10 (Friday) for within-week forecast horizon. It continues to 367 trading days or 367 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are presented in the appendix Tables A4.4a, A4.7a, A4.10a, and A4.13a, respectively.

For two-month maturity IV (hypothesis 2), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A4.1b in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 2. For example, the two-month maturity opening period IV_AUD (0.2115) in column 13 is calculated using the PCP pair on 31-May-10 (Monday) to forecast the RV_AUD (0.2130) in the last column on 04-Jun-10 (Friday) for within-week forecast horizon. It continues to 269 trading days or 269 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are explained in the appendix Tables A4.4b, A4.7b, A4.10b, and A4.13b, respectively.

For three-month maturity IV (hypothesis 3), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15, and 16, respectively. In column 12, the appendix Table A4.1c in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 3. For example, the three-month maturity opening period IV_AUD (0.1343) in column 13 is estimated for the PCP pair on 19-Apr-10 (Monday) to forecast the RV_AUD (0.0852) in the last column on 23-Apr-10 (Friday) for within-week forecast horizon. It continues to 241 trading days or 241 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A4.4c, A4.7c, A4.10c, and A4.13c, respectively.

**Table 3. 1: Put-call pair for hypothesis 1, hypothesis 2 and hypothesis 3
(IV forecast RV of currency for within-week forecast horizon)**

Within-week	One-month maturity IV (hypothesis 1)					Two-month maturity IV (hypothesis 2)					Three-month maturity IV (hypothesis 3)				
	AUD (A4.1a)	CAD (A4.4a)	CHF (A4.7a)	EUR (A4.10a)	GBP (A4.13a)	AUD (A4.1b)	CAD (A4.4b)	CHF (A4.7b)	EUR (A4.10b)	GBP (A4.13b)	AUD (A4.1c)	CAD (A4.4c)	CHF (A4.7c)	EUR (A4.10c)	GBP (A4.13c)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)	(16)
Panel A: Opening period (9:30-10:00)															
Mon-Fri	367	331	249	351	293	269	316	226	345	270	241	267	207	292	244

Notes: This table describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 1, 2, and 3, respectively. Panels A, B, and C present the PCPs of each currency for the within-week forecast horizon (Mon-Fri, Tue-Fri, Wed-Fri, and Thu-Fri) during the opening, midday, and closing period of a trading day, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A4.1a in the parenthesis below AUD is the appendix table which provides details of AUD options data for testing hypothesis 1. Similarly, A4.1b and A4.1c provides details of AUD options data for testing hypothesis 2 and hypothesis 3, respectively. The total sets/series of put-call pair is 180 [{panel A = 60 (4x15)} + {panel B = 60 (4x15)} + {panel C = 60 (4x15)}]

Table 3.2 describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 4, 5, and 6, respectively. The PCPs of each currency for the one-week forecast horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. For one-month maturity IV (hypothesis 4), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A4.2a in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 4. For example, the one-month maturity opening period IV_AUD (0.1689) in column 13 is estimated using PCP pair on 21-Jun-10 (Monday) to forecast the RV_AUD (0.0741) in the last column on 28-Jun-10 (Monday) for one-week forecast horizon. It continues to 366 trading days or 366 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are explained in the appendix Tables A4.5a, A4.8a, A4.11a, and A4.14a, respectively.

For two-month maturity IV (hypothesis 5), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A4.2b in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 5. For example, the two-month maturity opening period IV_AUD (0.2115) in column 13 is estimated based on the PCP pair on 31-May-10 (Monday) to forecast the RV_AUD (0.1226) in the last column on 07-Jun-10 (Monday) for the one-week forecast horizon. It continues to 268 trading days or 268 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A4.5b, A4.8b, A4.11b, and A4.14b, respectively.

For three-month maturity IV (hypothesis 6), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15, and 16, respectively. In column 12, the appendix Table A4.2c in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 6. For example, the three-month maturity opening period IV_AUD (0.1343) in column 13 is calculated for the PCP pair on 19-Apr-10 (Monday) to forecast the RV_AUD (0.0723) in the last column on 26-Apr-10 (Monday) for one-week forecast horizon. It continues to 240 trading days or 240 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are presented in the appendix Tables A4.5c, A4.8c, A4.11c, and A4.14c, respectively.

**Table 3. 2: Put-call pair for hypothesis 4, hypothesis 5 and hypothesis 6
(IV forecast RV of currency for one-week forecast horizon)**

One-week	One-month maturity IV (hypothesis 4)					Two-month maturity IV (hypothesis 5)					Three-month maturity IV (hypothesis 6)				
	AUD (A4.2a)	CAD (A4.5a)	CHF (A4.8a)	EUR (A4.11a)	GBP (A4.14a)	AUD (A4.2b)	CAD (A4.5b)	CHF (A4.8b)	EUR (A4.11b)	GBP (A4.14b)	AUD (A4.2c)	CAD (A4.5c)	CHF (A4.8c)	EUR (A4.11c)	GBP (A4.14c)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)	(16)

Notes: This table describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 4, 5, and 6, respectively. The PCPs of each currency for the one-week forecast horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A4.2a in the parenthesis below AUD is the appendix table which provides details of AUD options data for testing hypothesis 4. Similarly, A4.2b and A4.2c provides details of AUD options data for testing hypothesis 5 and hypothesis 6, respectively. The total sets/series of put-call pair is 225 [{panel A = 75 (5x15)} + {panel B = 75 (5x15)} + {panel C = 75 (5x15)}]

Table 3.3 describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 7, 8, and 9, respectively. The PCPs of each currency for one-month forecast horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. For one-month maturity IV (hypothesis 7), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A4.3a in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 7. For example, the one-month maturity opening period IV_AUD (0.1689) in column 13 is estimated using the PCP pair on 21-Jun-10 (Monday) to forecast the RV_AUD (0.0792) in the last column on 19-Jul-10 (Monday) for one-month forecast horizon. It continues to 364 trading days or 364 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are explained in the appendix Tables A4.6a, A4.9a, A4.12a, and A4.15a, respectively.

For two-month maturity IV (hypothesis 8), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A4.3b in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 8. For example, the two-month maturity opening period IV_AUD (0.2115) in column 13 is calculated based on the PCP pair on 31-May-10 (Monday) to forecast the RV_AUD (0.0741) in the last column on 28-Jun-10 (Monday) for one-month forecast horizon. It continues to 268 trading days or 268 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are described in the appendix Tables A4.6b, A4.9b, A4.12b, and A4.15b, respectively.

For three-month maturity IV (hypothesis 9), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15 and 16, respectively. In column 12, the appendix Table A4.3c in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 9. For example, the three-month maturity opening period IV_AUD (0.1343) in column 13 is computed for the PCP pair on 19-Apr-10 (Monday) to forecast the RV_AUD (0.1082) in the last column on 17-May-10 (Monday) for one-month forecast horizon. It continues to 239 trading days or 239 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A4.6c, A4.9c, A4.12c, and A4.15c, respectively.

**Table 3. 3: Put-call pair for hypothesis 7, hypothesis 8 and hypothesis 9
(IV forecast RV of currency for one-month forecast horizon)**

One-month	One-month maturity IV (hypothesis 7)					Two-month maturity IV (hypothesis 8)					Three-month maturity IV (hypothesis 9)				
	AUD (A4.3a)	CAD (A4.6a)	CHF (A4.9a)	EUR (A4.12a)	GBP (A4.15a)	AUD (A4.3b)	CAD (A4.6b)	CHF (A4.9b)	EUR (A4.12b)	GBP (A4.15b)	AUD (A4.3c)	CAD (A4.6c)	CHF (A4.9c)	EUR (A4.12c)	GBP (A4.15c)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)	(16)

Notes: This table describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 7, 8, and 9, respectively. The PCPs of each currency for one-month forecast horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A4.3a in the parenthesis below AUD is the appendix table which provides details of AUD option data for testing hypothesis 7. Similarly, A4.3b and A4.3c provides details of AUD options data for testing hypothesis 8 and hypothesis 9, respectively. The total sets/series of put-call pair is 225 [{panel A = 75 (5x15)} + {panel B = 75 (5x15)} + {panel C = 75 (5x15)}]

Table 3.4 explains the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 10, 11, and 12, respectively. The PCPs of each currency for the within-week estimate horizon (Mon-Fri, Tue-Fri, Wed-Fri, and Thu-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. The within-week estimate horizon indicates that the IV is estimated one day to four days before the date of pricing currency options. For one-month maturity IV (hypothesis 10), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A5.1a in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 10. For example, the one-month maturity opening period IV_AUD (0.1689) in column 13 is calculated using the PCP pair on 21-Jun-10 (Monday) to estimate the AUDC_MOD (1.92) and AUDP_MOD (1.00) in columns 17 and 18, respectively, on 25-Jun-10 (Friday) for within-week estimate horizon. It continues to 224 trading days or 224 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are described in the appendix Tables A5.4a, A5.7a, A5.10a, and A5.13a, respectively.

For two-month maturity IV (hypothesis 11), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A5.1b in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 11. For example, the two-month maturity opening period IV_AUD (0.1951) in column 13 is estimated for the PCP pair on 07-Jun-10 (Monday) to estimate the AUDC_MOD (2.18) and AUDP_MOD (1.43) in columns 17 and 18, respectively, on 11-Jun-10 (Friday) for within-week estimate horizon. It continues to 234 trading days or 234 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A5.4b, A5.7b, A5.10b, and A5.13b, respectively.

For three-month maturity IV (hypothesis 12), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15, and 16, respectively. In column 12, the appendix Table A5.1c in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 12. For example, the three-month maturity opening period IV_AUD (0.1099) in column 13 is computed based on the PCP pair on 03-May-10 (Monday) to estimate the AUDC_MOD (0.31) and AUDP_MOD (5.08) in columns 17 and 18, respectively, on 07-May-10 (Friday) for within-week estimate horizon. It continues to 186 trading days or 186 PCP

pairs. Similarly, the CAD, CHF EUR, and GBP options data details are presented in the appendix Tables A5.4c, A5.7c, A5.10c, and A5.13c, respectively.

**Table 3. 4: Put-call pair for hypothesis 10, hypothesis 11 and hypothesis 12
(IV estimate currency options price for within-week estimate horizon)**

Within-week	One-month maturity IV (hypothesis 10)					Two-month maturity IV (hypothesis 11)					Three-month maturity IV (hypothesis 12)

Notes: This table explains the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 10, 11, and 12, respectively. The PCPs of each currency for the within-week estimate horizon (Mon-Fri, Tue-Fri, Wed-Fri, and Thu-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A5.1a in the parenthesis below AUD is the appendix table which provides details of AUD options data for testing hypothesis 10. Similarly, A5.1b and A5.1c provides details of AUD options data for testing hypothesis 11 and hypothesis 12, respectively. The total sets/series of put-call pair is 180 [(panel A = 60 (4x15)) + (panel B = 60 (4x15)) + (panel C = 60 (4x15))]. The within-week estimate horizon indicates that the IV is estimated one day to four days before the date of pricing currency options.

Table 3.5 describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 13, 14, and 15, respectively. The PCPs of each currency for the one-week estimate horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. The one-week estimate horizon implies that the IV is estimated one-week before the date of pricing currency options. For one-month maturity IV (hypothesis 13), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A5.2a in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 13. For example, the one-month maturity opening period IV_AUD (0.1697) in column 13 is estimated using the PCP pair on 21-Jun-10 (Monday) to calculate the AUDC_MOD (3.16) and AUDP_MOD (0.38) in columns 17 and 18, respectively, on 28-Jun-10 (Monday) for one-week estimate horizon. It continues to 201 trading days or 201 PCP pairs. Similarly, the CAD, CHF, EUR, and GBP options data details are given in the appendix Tables A5.5a, A5.8a, A5.11a, and A5.14a, respectively.

For two-month maturity IV (hypothesis 14), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A5.2b in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 14. For example, the two-month maturity opening period IV_AUD (0.2314) in column 13 is computed for the PCP pair on 24-May-10 (Monday) to estimate the AUDC (3.99) and AUDP (0.30) in columns 17 and 18, respectively, on 31-May-10 (Monday) for one-week estimate horizon. It continues to 233 trading days or 233 PCP pairs. Similarly, the CAD, CHF, EUR, and GBP options data details are described in the appendix Tables A5.5b, A5.8b, A5.11b, and A5.14b, respectively.

For three-month maturity IV (hypothesis 15), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15 and 16, respectively. In column 12, the appendix Table A5.2c in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 15. For example, the three-month maturity opening period IV_AUD (0.1366) in column 13 is calculated based on the PCP pair on 19-Apr-10 (Monday) to estimate the AUDC_MOD (4.02) and AUDP_MOD (0.67) in columns 17 and 18, respectively, on 26-Apr-10 (Monday) for one-week estimate horizon. It continues to 185 trading days or 185 PCP

pairs. Similarly, the CAD, CHF EUR, and GBP options data details are presented in the appendix Tables A5.5c, A5.8c, A5.11c, and A5.14c, respectively.

**Table 3. 5: Put-call pairs for hypothesis 13, hypothesis 14 and hypothesis 15
(IV estimate currency options price for one-week estimate horizon)**

Notes: This table describes the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 13, 14, and 15, respectively. The PCPs of each currency for the one-week estimate horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A5.2a in the parenthesis below AUD is the appendix table which provides details of AUD options data for testing hypothesis 13. Similarly, A5.2b and A5.2c provides details of AUD options data for testing hypothesis 14 and hypothesis 15, respectively. The total sets/series of put-call pair is $225 \times \{ \text{panel A} = 75 (5 \times 15) \} + \{ \text{panel B} = 75 (5 \times 15) \} + \{ \text{panel C} = 75 (5 \times 15) \}$. The one-week estimate horizon implies that the IV is estimated one-week before the date of pricing currency options.

Table 3.6 explains the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 16, 17, and 18, respectively. The PCPs of each currency for the one-month estimate horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. The one-month estimate horizon implies that the IV is estimated one-month before the date of pricing currency options. For one-month maturity IV (hypothesis 16), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 2, 3, 4, 5, and 6, respectively. In column 2, the appendix Table A5.3a in the parenthesis below AUD provides the details of AUD options data for testing hypothesis 16. For example, the one-month maturity opening period IV_AUD (0.2663) in column 13 is calculated based on the PCP pair on 21-Jun-10 (Monday) to estimate the AUDC_MOD (1.18) and AUDP_MOD (1.68) in columns 17 and 18, respectively, 12-Jul-10 (Monday) for one-month estimate horizon. It continues to 151 trading days or 151 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A5.6a, A5.9a, A5.12a, and A5.15a, respectively.

For two-month maturity IV (hypothesis 17), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 7, 8, 9, 10, and 11, respectively. In column 7, the appendix Table A5.3b in the parenthesis below AUD shows the details of AUD options data for testing hypothesis 17. For example, the two-month maturity opening period IV_AUD (0.1951) in column 13 is calculated using the PCP pair on 07-Jun-10 (Monday) to estimate the AUDC_MOD (1.69) and AUDP_MOD (0.78) in columns 17 and 18, respectively, on 05-Jul-10 (Monday) for one-month forecast horizon. It continues to 161 trading days or 161 PCP pairs. Similarly, the CAD, CHF EUR, and GBP options data details are described in the appendix Tables A5.6b, A5.9b, A5.12b, and A5.15b, respectively.

For three-month maturity IV (hypothesis 18), the total PCPs of AUD, CAD, CHF, EUR, and GBP options are reported in columns 12, 13, 14, 15 and 16, respectively. In column 12, the appendix Table A5.3c in the parenthesis below AUD presents the details of AUD options data for testing hypothesis 18. For example, the three-month maturity opening period IV_AUD (0.1289) in column 13 is computed for the PCP pair on 17-May-10 (Monday) to estimate the AUDC_MOD (0.16) and AUDP_MOD (4.51) in columns 17 and 19, respectively, on 14-Jun-10 (Monday) for one-month estimate horizon. It continues to 178 trading days or 178 PCP

pairs. Similarly, the CAD, CHF EUR, and GBP options data details are given in the appendix Tables A5.6c, A5.9c, A5.12c, and A5.15c, respectively.

**Table 3. 6: Put-call pair for hypothesis 16, hypothesis 17 and hypothesis 18
(IV estimate currency options price for one-month estimate horizon)**

Notes: This table explains the PCP in estimating the IV based on the price of call and put options with one-month, two-month, and three-month maturity to test hypotheses 16, 17, and 18, respectively. The PCPs of each currency for the one-month estimate horizon (Mon-Mon, Tue-Tue, Wed-Wed, Thu-Thu, and Fri-Fri) during the opening, midday, and closing period are presented in panel A, B, and C, respectively. IV and RV represents implied volatility and realized volatility, respectively. The appendix table reference is in the parenthesis below the each of currency symbol. For example, A5.3a in the parenthesis below AUD is the appendix table which provides details of AUD options data for testing hypothesis 16. Similarly, A5.3b and A5.3c provides details of AUD options data for testing hypothesis 17 and hypothesis 18, respectively. The total sets/series of put-call pair is 225 [{panel A = 75 (5x15)} + {panel B = 75 (5x15)} + {panel C = 75 (5x15)}]. The one-month estimate horizon implies that the IV is estimated one-month before the date of pricing currency options.

3.8 Conclusion

Chapter 3 provides the methodology for testing the eighteen (18) hypotheses through the following five empirical methods. First, estimate the IV based on the price of options with one-month, two-month, and three-month maturity during the opening, midday, and closing period of a trading day. The BSM options pricing model estimates IV using ATM call and put options price through Newton-Raphson iterative search procedure. Second, estimate the RV for the underlying currency of options and using it as the proxy for the actual foreign exchange volatility. The RV is constructed by summing the squared five-minute intraday returns of the underlying currency of options. Third, analyse the performance of IV to forecast RV for the within-week, one-week, and one-month forecast horizon. The RV is regressed on IV in the MZ regression test and the higher value of R^2 that leading to the superior performance of IV to forecast RV. Fourth, calculate the CMOD and PMOD using the estimated IV in the first empirical method as input for the BSM options pricing model. Fifth, compute the OPE as the difference between the observed ATM options market price and the estimated options model price in the fourth empirical method. The OPE is generated under MAE, MSE, and RMSE measures to evaluate the performance of IV for pricing currency options for the within-week, one-week, and one-month estimate horizon.

This study uses the intraday data for AUD, CAD, CHF, EUR, and GBP European currency options provided by the OPRA as the last-sale options quotations. The sample period begins on 01 January 2010 and ends on 31 December 2017 for all currencies. The options are traded on Monday to Friday, excluding public holidays from 9:30 to 16:00 (US Eastern standard time) and expire on the third Friday of each month. The contract size of five sample currency options is AUD10,000, CAD10,000, CHF10,000, EUR10,000, and GBP 10,000, and settle in US dollar. The option with the time to maturity ranging from 2 days to less than or equal to 30 days is considered to be a one-month maturity option. The two-month maturity options include those that have time to maturity is between 31 days to less than or equal to 60 days. The options that have time to maturity covering from 61 days to 90 days are considered to be the three-month maturity options. All sample options are used to construct the intraday IV for the opening period (9:30 to 10:00), midday period (12:30 to 13:00), and closing period (15:30 to 16:00) of a trading day.

CHAPTER 4

Implied Volatility Forecasting Realized Volatility

4.1 Introduction

This chapter conducts an empirical analysis of IV to forecast the RV through testing hypothesis 01 to hypothesis 09. The analysis includes three steps. First, estimate the IV for ATM price of currency options with one-month, two-month, and three-month maturity during opening, midday, and closing period. Second, estimate the RV of currency to use as the proxy for the actual volatility. Finally, assess the performance of IV to forecast RV accurately for the within-week, one-week, and one-month forecast horizon.

4.2 Implied and realized volatility estimation

Volatility has become a critical issue for investors, portfolio managers, asset valuation, hedging strategy, risk management purposes (Barunik et al., 2016; Charles, 2010; Christodoulakis, 2007; Fuertes et al., 2009). It is essential for the options market participants dealing with financial instruments to grasp risk, accurately predict it, and control the impact of risk on their investment portfolios. The current option pricing philosophy, beginning with BS, plays a central role in assessing the fair value of an option. The volatility of the underlying assets is one of five parameters in the BS options pricing model, but its value is further amplified by the fact that it is the only one not directly observable. The spot price, strike price, trade date, expiration date, domestic interest rate, and foreign currency interest rate are readily available on the market, but volatility must be forecasted. While the observed variance can accurately be calculated using historical data from past years, the option's theoretical price today depends on the volatility that will be experienced in the future, over the entire lifetime of the options. Thus, volatility forecasting is crucial for the options pricing.

Currently, the attention of researchers and practitioners has lied on the IV deriving from options market prices. Empirical studies indicate that IV contains more useful information than that based on historical prices (Frijin et al., 2010). The ranges of volatility prediction horizons examined vary; however, one week, one month, and three months are the most popular choice. The IV of ATM options price provides a reasonably accurate forecast in the FX market. The IV tends to be low and high in the early and later part of the week, respectively. It follows due to the weekday pattern of scheduled news releases, the IV falls on Fridays and rises on Mondays. The empirical studies on IV often find that all the relevant information for forecasting volatility of an underlying asset can be found in the options market prices. However, IV holds the discrete information regarding the FX movement at a specific time of the trading day (Hoque & Kaley, 2015). Therefore, IV that captures the intraday level aggregate information related to FX behaviour, that changes every five minutes, needs to be tested to find out whether intraday IV holds appropriate information in forecasting FX volatility.

Appendix Table A4.1a describes the data to estimate one-month maturity IV_AUD during the opening, midday, and closing period of AUD options price for the within-week forecast horizon. The IV_AUDC is computed in column 11 using the time-to-maturity (expiry date – trade date), call price, strike price, spot price, IR_AUD, IR_USD as inputs for the equation

(3.5). Similarly, the IV_AUDP is calculated in column 12 using time-to-maturity, put price, strike price, spot price, IR_AUD, IR_USD as inputs for the equation (3.6). The IV_AUD in column 13 is the average of IV_AUDC and IV_AUDP, as in the equation (3.7). Similarly, the appendix Tables A4.1b and A4.1c show the details of data to calculate the two-month and three-month maturity IV_AUD, respectively, for the within-week forecast horizon. Further, the appendix Tables A4.2a, A4.2b, and A4.2c illustrate the details of data to estimate the one-month, two-month, and three-month maturity IV_AUD, respectively, during the opening, midday, and closing period for the one-week forecast horizon. Finally, the appendix Tables A4.3a, A4.3b, and A4.3c describe the details of data to estimate one-month, two-month, and three-month maturity IV_AUD, respectively, during the opening, midday, and closing period for the one-month forecast horizon.

Appendix Table A4.4a explains the data to estimate one-month maturity IV_CAD during the opening, midday, and closing period of CAD options price for the within-week forecast horizon. The IV_CADC is computed in column 11 using the time-to-maturity (expiry date – trade date), call price, strike price, spot price, IR_CAD, IR_USD as inputs for the equation (3.5). Similarly, the IV_CADP is calculated in column 12 using time-to-maturity, put price, strike price, spot price, IR_CAD, IR_USD as inputs for the equation (3.6). The IV_CAD in column 13 is the average of IV_CADC and IV_CADP, as in the equation (3.7). Similarly, the appendix Tables A4.4b and A4.4c show the details of data to estimate the two-month and three-month maturity IV_CAD, respectively, for the within-week forecast horizon. Further, the appendix Tables A4.5a, A4.5b, and A4.5c discuss the details of data to estimate the one-month, two-month, and three-month maturity IV_CAD, respectively, during the opening, midday, and closing period for the one-week forecast horizon. Finally, the appendix Tables A4.6a, A4.6b, and A4.6c describe the details of data to estimate one-month, two-month, and three-month maturity IV_CAD, respectively, during the opening, midday, and closing period for the one-month forecast horizon.

Appendix Table A4.7a describes the data to estimate one-month maturity IV_CHF during the opening, midday, and closing period of CHF options price for the within-week forecast horizon. The IV_CHFC is estimated in column 11 using the time-to-maturity (expiry date – trade date), call price, strike price, spot price, IR_CHF, IR_USD as inputs for the equation (3.5). Similarly, the IV_CHFP is calculated in column 12 using time-to-maturity, put price, strike price, spot price, IR_CHF, IR_USD as inputs for the equation (3.6). The IV_CHF in column 13 is the

average of IV_CHFC and IV_CHFP, as in the equation (3.7). Similarly, the appendix Tables A4.7b and A4.7c provide the details of data to estimate the two-month and three-month maturity IV_CHF, respectively, for the within-week forecast horizon. Further, the appendix Tables A4.8a, A4.8b, and A4.8c discuss the details of data to calculate the one-month, two-month, and three-month maturity IV_CHF, respectively, during the opening, midday, and closing period for the one-week forecast horizon. Finally, the appendix Tables A4.9a, A4.9b, and A4.9c illustrate the details of data to estimate one-month, two-month, and three-month maturity IV_CHF, respectively, during the opening, midday, and closing period for the one-month forecast horizon.

Appendix Table A4.10a explain the data to estimate one-month maturity IV_EUR during the opening, midday, and closing period of EUR options price for the within-week forecast horizon. The IV_EURC is computed in column 11 using the time-to-maturity (expiry date – trade date), call price, strike price, spot price, IR_EUR, IR_USD as inputs for the equation (3.5). Similarly, the IV_EURP is calculated in column 12 using time-to-maturity, put price, strike price, spot price, IR_EUR, IR_USD as inputs for the equation (3.6). The IV_EUR in column 13 is the average of IV_EURC and IV_EURP, as in the equation (3.7). Similarly, the appendix Tables A4.10b and A4.10c provide the details of data to estimate the two-month and three-month maturity IV_EUR, respectively, for the within-week forecast horizon. Further, the appendix Tables A4.11a, A4.11b, and A4.11c discuss the details of data to estimate the one-month, two-month, and three-month maturity IV_EUR, respectively, during the opening, midday, and closing period for the one-week forecast horizon. Finally, the appendix Tables A4.12a, A4.12b, and A4.12c describe the details of data to estimate one-month, two-month, and three-month maturity IV_EUR, respectively, during the opening, midday, and closing period for the one-month forecast horizon.

Appendix Table A4.13a explains the data to estimate one-month maturity IV_GBP during the opening, midday, and closing period of GBP options price for the within-week forecast horizon. The IV_GBPC is compute in column 11 using the time-to-maturity (expiry date – trade date), call price, strike price, spot price, IR_GBP, IR_USD as inputs for the equation (3.5). Similarly, the IV_GBPP is calculated in column 12 using time-to-maturity, put price, strike price, spot price, IR_GBP, IR_USD as inputs for the equation (3.6). The IV_GBP in column 13 is the average of IV_GBPC and IV_GBPP, as in the equation (3.7). Similarly, the appendix Tables A4.13b and A4.13c provide the details of data to calculate the two-month and three-month

maturity IV_GBP, respectively, for the within-week forecast horizon. Further, the appendix Tables A4.14a, A4.14b, and A4.14c present the details of data to estimate the one-month, two-month, and three-month maturity IV_GBP, respectively, during the opening, midday, and closing period for the one-week forecast horizon. Finally, the appendix Tables A4.15a, A4.15b, and A4.15c describe the details of data to estimate one-month, two-month, and three-month maturity IV_GBP, respectively, during the opening, midday, and closing period for the one-month forecast horizon.

The availability of intraday data for financial assets has led to the increasing developments in econometrics and quantitative finance (Qiao et al., 2019). High-frequency data that provides more intraday trading information is vital for all market participants. Andersen and Bollerslev (1998) first introduced the RV that based on the sum of squared intraday returns of an asset and showed that it is a more practical approach to modelling the volatility. The most valuable feature of RV is that it provides a consistent non-parametric estimation of volatility with a less influenced by the measurement error. Since the actual volatility is unobservable, Kourtis et al. (2016) use RV as the proxy for the actual volatility. Therefore, this study considers RV as the actual volatility of the underlying currency of options. Appendix Table A4.1a estimates the RV_AUD in column 16 (last column) for the five-minute interval AUD spot rate reported in column 8 using the equation (3.11). Similarly, the RV_CAD, RV_CHF, RV_EUR, and RV_GBP is calculated for the five-minute interval Canadian dollar, Swiss franc, Euro, and British pound spot price, respectively.

4.3 Implied volatility forecasting evaluation

The performance of IV to forecast the RV of the underlying currency of options is evaluated for the within-week, one-week, and one-month forecast horizon. For the within-week forecast horizon, the opening period, midday period, and closing period IV of Monday, Tuesday, Wednesday, and Thursday are used to forecast the RV at the corresponding time on Friday in the same week. Appendix Table A4.1a shows the one-month maturity IV_AUD in column 13 of Monday, Tuesday, Wednesday, and Thursday forecast RV_AUD in column 16 of Friday for the opening, midday, and closing period in panels A, B, and C, respectively. Further, the two-month maturity IV_AUD forecast RV_AUD and three-month maturity IV_AUD forecast RV_AUD is illustrated in the Tables A4.1b and A4.1c, respectively. Similarly, one-month, two-month and three-month maturity IV forecast RV for the CAD options (appendix Tables A4.4a, A4.4b, and A4.4c), CHF options (appendix Tables A4.7a, A4.7b, Table A4.7c), EUR options (appendix Tables A4.10a, A4.10b, and A4.10c), and GBP options (appendix Tables A4.13a, A4.13b, and A4.13c) are explained.

For the one-week forecast horizon, the opening period, midday period, and closing period IV of Monday, Tuesday, Wednesday, Thursday, and Friday of a week are used to forecast the RV at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next week, respectively. Appendix Table A4.2a explains the one-month maturity IV_AUD in column 13 of Monday, Tuesday, Wednesday, Thursday, and Friday forecast RV_AUD in column 16 of Monday, Tuesday, Wednesday, Thursday, and Friday for the opening, midday, and closing period in panels A, B, and C, respectively. Further, the two-month maturity IV_AUD forecast RV_AUD and three-month maturity IV_AUD forecast RV_AUD is presented in the Tables A4.2b and A4.2c, respectively. Similarly, one-month, two-month and three-month maturity IV forecast RV for the CAD options (appendix Tables A4.5a, A4.5b, and A4.5c), CHF options (appendix Tables A4.8a, A4.8b, Table A4.8c), EUR options (appendix Tables A4.11a, A4.11b, and A4.11c), and GBP options (appendix Tables A4.14a, A4.14b, and A4.14c) are described.

For the one-month forecast horizon, the opening period, midday period, and closing period IV of Monday, Tuesday, Wednesday, Thursday, and Friday of a month are used to forecast the RV at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next month, respectively. Appendix Table A4.3a explains the one-month maturity IV_AUD in

column 13 of Monday, Tuesday, Wednesday, Thursday, and Friday forecast RV_AUD in column 16 of Monday, Tuesday, Wednesday, Thursday, and Friday for the opening, midday, and closing period in panels A, B, and C, respectively. Further, the two-month maturity IV_AUD forecast RV_AUD and three-month maturity IV_AUD forecast RV_AUD is reported in the Tables A4.3b and A4.3c, respectively. Similarly, one-month, two-month and three-month maturity IV forecast RV for the CAD options (appendix Tables A4.6a, A4.6b, and A4.6c), CHF options (appendix Tables A4.9a, A4.9b, Table A4.9c), EUR options (appendix Tables A4.12a, A4.12b, and A4.12c), and GBP options (appendix Tables A4.15a, A4.15b, and A4.15c) are explained.

4.4 Empirical analysis

The empirical analysis is conducted through Mincer-Zarnowitz (MZ) regression model, as in equation (3.12), evaluating the performance of IV to forecast RV. The total 630 regression analysis has performed based on the 630 sets of put-call pairs (PCPs) (180, 225, and 225 sets of PCPs in Tables 3.1, 3.2, and 3.3). The joint test is examined the hypothesis: $\beta_0 = 0$ and $\beta_1 = 1$. The R^2 (goodness-of-fit) of the regression is employed as the measurement of the predictive power of the IV. Therefore, the high R^2 value is expected that leading to the superior performance of IV to forecast RV.

Table 4.1 shows the performance of IV_AUD to forecast RV_AUD for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_AUD ($R^2 = 0.1958$) of Tuesday performs better than that of Monday, Wednesday, and Thursday to forecast RV_AUD on Friday in the same week. The two-month maturity IV_AUD ($R^2 = 0.3362$) and three-month maturity IV_AUD ($R^2 = 0.2888$) of Tuesday are also better to forecast RV_AUD. However, two-month maturity IV_AUD outperforms one-month and three-month maturity IV_AUD in forecasting RV_AUD. Similarly, two-month maturity IV_AUD ($R^2 = 0.2809$) of Tuesday is superior to forecast RV_AUD for the midday period. However, two-month maturity IV_AUD ($R^2 = 0.3796$) of Monday is better to forecast RV_AUD for the closing period.

Table 4.1: IV_AUD forecast RV_AUD for within-week forecast horizon

Forecast Horizon	One-month maturity IV_AUD (hypothesis 1)			Two-month maturity IV_AUD (hypothesis 2)			Three-month maturity IV_AUD (hypothesis 3)		
	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²
Panel A: Opening period (9:30 – 10:00)

Notes: This table shows the performance of IV_AUD to forecast RV_AUD for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_AUD and RV_AUD represent the implied volatility of Australian dollar options and the realized volatility of the Australian dollar, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_AUD during the opening period) that leading to better performance of IV_AUD to forecast RV_AUD.

Table 4.2 presents the performance of IV_AUD to forecast RV_AUD for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_AUD ($R^2 = 0.4659$) of Tuesday performs better than that of Monday, Wednesday, Thursday, and Friday to forecast RV_AUD at the corresponding time on Tuesday of the next week. The two-month maturity IV_AUD ($R^2 = 0.3658$) and three-month maturity IV_AUD ($R^2 = 0.2845$) of Tuesday are also better to forecast RV_AUD. However, one-month maturity IV_AUD outperforms two-month and three-month maturity IV_AUD in forecasting RV_AUD. Similarly, one-month maturity IV_AUD ($R^2 = 0.4328$) of Tuesday performs better to forecast RV_AUD for the midday period. However, one-month maturity IV_AUD ($R^2 = 0.4721$) of Monday is superior to forecast RV_AUD for the closing period.

Table 4.2: IV_AUD forecast RV_AUD for one-week forecast horizon

Forecast Horizon	One-month maturity IV_AUD (hypothesis 4)			Two-month maturity IV_AUD (hypothesis 5)			Three-month maturity IV_AUD (hypothesis 6)

Notes: This table presents the performance of IV_AUD to forecast RV_AUD for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_AUD and RV_AUD represent the implied volatility of Australian dollar options and the realized volatility of the Australian dollar, respectively. The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one. * denotes a higher value of R² for each situation (e.g., one-month maturity IV_AUD during the opening period) that leading to better performance of IV_AUD to forecast RV_AUD.

Table 4.3 explains the performance of IV_AUD to forecast RV_AUD for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_AUD ($R^2 = 0.2284$) of Tuesday performs better than that of Monday, Wednesday, Thursday, and Friday to forecast RV_AUD at the corresponding time on Tuesday of the next month. The two-month maturity IV_AUD ($R^2 = 0.3861$) and three-month maturity IV_AUD ($R^2 = 0.2959$) of Tuesday are also better to forecast RV_AUD. However, two-month maturity IV_AUD outperforms one-month and three-month maturity IV_AUD in forecasting RV_AUD. Similarly, two-month maturity IV_AUD ($R^2 = 0.3328$) of Tuesday performs better to forecast RV_AUD for the midday period. The two-month maturity IV_AUD ($R^2 = 0.3933$) of Tuesday is also superior to forecast RV_AUD for the closing period.

Table 4.3: IV_AUD forecast RV_AUD for one-month forecast horizon

Forecast Horizon	One-month maturity IV_AUD (hypothesis 7)			Two-month maturity IV_AUD (hypothesis 8)			Three-month maturity IV_AUD (hypothesis 9)		
	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²

Notes: This table explains the performance of IV_AUD to forecast RV_AUD for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_AUD and RV_AUD represent the implied volatility of Australian dollar options and the realized volatility of the Australian dollar, respectively. The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one. * denotes a higher value of R² for each situation (e.g., one-month maturity IV_AUD during the opening period) that leading to better performance of IV_AUD to forecast RV_AUD.

Table 4.4 shows the performance of IV_CAD to forecast RV_CAD for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CAD ($R^2 = 0.1749$) of Monday performs better than that of Tuesday, Wednesday, and Thursday to forecast RV_CAD on Friday in the same week. The two-month maturity IV_CAD ($R^2 = 0.2769$) and three-month maturity IV_CAD ($R^2 = 0.2106$) of Monday are also better to forecast RV_CAD. However, two-month maturity IV_CAD outperforms one-month and three-month maturity IV_CAD in forecasting RV_CAD. Further, two-month maturity IV_CAD ($R^2 = 0.2437$) of Wednesday performs better to forecast RV_CAD for the midday period. However, two-month maturity IV_CAD ($R^2 = 0.2978$) of Tuesday is superior to forecast RV_AUD for the closing period.

Table 4.4: IV_CAD forecast RV_CAD for within-week forecast horizon

Forecast Horizon	One-month maturity IV_CAD (hypothesis 1)			Two-month maturity IV_CAD (hypothesis 2)			Three-month maturity IV_CAD (hypothesis 3)		
	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²

Notes: This table shows the performance of IV_CAD to forecast RV_CAD for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CAD and RV_CAD represent the implied volatility of Canadian dollar options and the realized volatility of the Canadian dollar, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CAD during the opening period) that leading to better performance of IV_CAD to forecast RV_CAD.

Table 4.5 presents the performance of IV_CAD to forecast RV_CAD for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CAD ($R^2 = 0.4899$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_CAD at the corresponding time on Monday of the next week. The two-month maturity IV_CAD ($R^2 = 0.3629$) and three-month maturity IV_CAD ($R^2 = 0.3435$) of Monday are also better to forecast RV_CAD. However, one-month maturity IV_CAD outperforms two-month and three-month maturity IV_CAD in forecasting RV_CAD. Similarly, one-month maturity IV_CAD ($R^2 = 0.4076$) of Monday performs better to forecast RV_CAD for the midday period. The one-month maturity IV_CAD ($R^2 = 0.4911$) of Monday is also superior to forecast RV_CAD for the closing period.

Table 4.5: IV_CAD forecast RV_CAD for one-week forecast horizon

Notes: This table presents the performance of IV_CAD to forecast RV_CAD for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CAD and RV_CAD represent the implied volatility of Canadian dollar options and the realized volatility of the Canadian dollar, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CAD during the opening period) that leading to better performance of IV_CAD to forecast RV_CAD.

Table 4.6 shows the performance of IV_CAD to forecast RV_CAD for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CAD ($R^2 = 0.1872$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_CAD at the corresponding time on Monday of the next month. The two-month maturity IV_CAD ($R^2 = 0.3471$) and three-month maturity IV_CAD ($R^2 = 0.2723$) of Monday are also better to forecast RV_CAD. However, two-month maturity IV_CAD outperforms one-month and three-month maturity IV_CAD in forecasting RV_CAD. Further, two-month maturity IV_CAD ($R^2 = 0.3442$) of Tuesday performs better to forecast RV_CAD for the midday period. Similarly, two-month maturity IV_CAD ($R^2 = 0.3519$) of Tuesday is superior to forecast RV_CAD for the closing period.

Notes: This table shows the performance of IV_CAD to forecast RV_CAD for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CAD and RV_CAD represent the implied volatility of Canadian dollar options and the realized volatility of the Canadian dollar, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CAD during the opening period) that leading to better performance of IV_CAD to forecast RV_CAD.

Table 4.7 explains the performance of IV_CHF to forecast RV_CHF for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CHF ($R^2 = 0.3419$) of Thursday performs better than that of Monday, Tuesday, and Wednesday to forecast RV_CHF on Friday in the same week. The two-month maturity IV_CHF ($R^2 = 0.3124$) and three-month maturity IV_CHF ($R^2 = 0.2304$) of Thursday are also better to forecast RV_CHF. However, one-month maturity IV_CHF outperforms two-month and three-month maturity IV_CHF in forecasting RV_CHF. Similarly, one-month maturity IV_CHF ($R^2 = 0.3474$) of Thursday performs better to forecast RV_CHF for the midday period. The one-month maturity IV_CHF ($R^2 = 0.3600$) of Thursday is also superior to forecast RV_CHF for the closing period.

Table 4.7: IV_CHF forecast RV_CHF for within-week forecast horizon

Forecast Horizon	One-month maturity IV_CHF (hypothesis 1)			Two-month maturity IV_CHF (hypothesis 2)			Three-month maturity IV_CHF (hypothesis 3)

Notes: This table explains the performance of IV_CHF to forecast RV_CHF for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CHF and RV_CHF represent the implied volatility of Swiss Franc options and the realized volatility of the Swiss Franc, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CHF during the opening period) that leading to better performance of IV_CHF to forecast RV_CHF.

Table 4.8 shows the performance of IV_CHF to forecast RV_CHF for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CHF ($R^2 = 0.4419$) of Tuesday performs better than that of Monday, Wednesday, Thursday, and Friday to forecast RV_CHF at the corresponding time on Tuesday of the next week. The two-month maturity IV_CHF ($R^2 = 0.3596$) and three-month maturity IV_CHF ($R^2 = 0.3745$) of Tuesday are also better to forecast RV_CHF. However, one-month maturity IV_CHF outperforms two-month and three-month maturity IV_CHF in forecasting RV_CHF. Similarly, one-month maturity IV_CHF ($R^2 = 0.3713$) of Tuesday performs better to forecast RV_CHF for the midday period. The one-month maturity IV_CHF ($R^2 = 0.4739$) of Tuesday is also superior to forecast RV_CHF for the closing period.

Notes: This table shows the performance of IV_CHF to forecast RV_CHF for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CHF and RV_CHF represent the implied volatility of Swiss Franc options and the realized volatility of the Swiss Franc, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CHF during the opening period) that leading to better performance of IV_CHF to forecast RV_CHF.

Table 4.9 shows the performance of IV_CHF to forecast RV_CHF for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_CHF ($R^2 = 0.2904$) of Tuesday performs better than that of Monday, Wednesday, Thursday, and Friday to forecast RV_CHF at the corresponding time on Tuesday of the next month. The two-month maturity IV_CHF ($R^2 = 0.3185$) and three-month maturity IV_CHF ($R^2 = 0.2027$) of Tuesday are also better to forecast RV_CHF. However, two-month maturity IV_CHF outperforms one-month and three-month maturity IV_CHF in forecasting RV_CHF. Similarly, two-month maturity IV_CHF ($R^2 = 0.2415$) of Tuesday performs better to forecast RV_CHF for the midday period. The two-month maturity IV_CHF ($R^2 = 0.3214$) of Tuesday is also superior to forecast RV_CHF for the closing period.

Table 4.9: IV_CHF forecast RV_CHF for one-month forecast horizon

Notes: This table shows the performance of IV_CHF to forecast RV_CHF for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_CHF and RV_CHF represent the implied volatility of Swiss Franc options and the realized volatility of the Swiss Franc, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_CHF during the opening period) that leading to better performance of IV_CHF to forecast RV_CHF.

Table 4.10 explains the performance of IV_EUR to forecast RV_EUR for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_EUR ($R^2 = 0.1484$) of Monday performs better than that of Tuesday, Wednesday, and Thursday to forecast RV_EUR on Friday in the same week. The two-month maturity IV_EUR ($R^2 = 0.2241$) and three-month maturity IV_EUR ($R^2 = 0.2158$) of Monday are also better to forecast RV_EUR. However, two-month maturity IV_EUR outperforms one-month and three-month maturity IV_EUR in forecasting RV_EUR. Further, two-month maturity IV_EUR ($R^2 = 0.1863$) of Tuesday performs better to forecast RV_EUR for the midday period. Similarly, two-month maturity IV_EUR ($R^2 = 0.2335$) of Tuesday is superior to forecast RV_EUR for the closing period.

Table 4.10: IV_EUR forecast RV_EUR for within-week forecast horizon

Notes: This table explains the performance of IV_EUR to forecast RV_EUR for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_EUR and RV_EUR represent the implied volatility of Euro options and the realized volatility of the Euro, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_EUR during the opening period) that leading to better performance of IV_EUR to forecast RV_EUR.

Table 4.11 presents the performance of IV_EUR to forecast RV_EUR for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_EUR ($R^2 = 0.4359$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_EUR at the corresponding time on Monday of the next week. The two-month maturity IV_EUR ($R^2 = 0.3579$) and three-month maturity IV_EUR ($R^2 = 0.2679$) of Monday are also better to forecast RV_EUR. However, one-month maturity IV_EUR outperforms two-month and three-month maturity IV_EUR in forecasting RV_EUR. Similarly, one-month maturity IV_EUR ($R^2 = 0.3659$) of Monday performs better to forecast RV_EUR for the midday period. The one-month maturity IV_EUR ($R^2 = 0.4406$) of Monday is also superior to forecast RV_EUR for the closing period.

Table 4.11: IV_EUR forecast RV_EUR for one-week forecast horizon

Forecast Horizon	One-month maturity IV_EUR (hypothesis 4)			Two-month maturity IV_EUR (hypothesis 5)			Three-month maturity IV_EUR (hypothesis 6)

Notes: This table presents the performance of IV_EUR to forecast RV_EUR for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_EUR and RV_EUR represent the implied volatility of Euro options and the realized volatility of the Euro, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_EUR during the opening period) that leading to better performance of IV_EUR to forecast RV_EUR.

Table 4.12 shows the performance of IV_EUR to forecast RV_EUR for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_EUR ($R^2 = 0.2431$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_EUR at the corresponding time on Monday of the next month. The two-month maturity IV_EUR ($R^2 = 0.3721$) and three-month maturity IV_EUR ($R^2 = 0.2877$) of Monday are also better to forecast RV_EUR. However, two-month maturity IV_EUR outperforms one-month and three-month maturity IV_EUR in forecasting RV_EUR. Further, two-month maturity IV_EUR ($R^2 = 0.3116$) of Tuesday performs better to forecast RV_EUR for the midday period. However, two-month maturity IV_EUR ($R^2 = 0.3814$) of Monday is superior to forecast RV_EUR for the closing period.

Table 4.12: IV_EUR forecast RV_EUR for one-month forecast horizon

Notes: This table shows the performance of IV_EUR to forecast RV_EUR for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_EUR and RV_EUR represent the implied volatility of Euro options and the realized volatility of the Euro, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_EUR during the opening period) that leading to better performance of IV_EUR to forecast RV_EUR.

Table 4.13 presents the performance of IV_GBP to forecast RV_GBP for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_GBP ($R^2 = 0.3704$) of Thursday performs better than that of Monday, Tuesday, and Wednesday to forecast RV_GBP on Friday in the same week. The two-month maturity IV_GBP ($R^2 = 0.2749$) and three-month maturity IV_GBP ($R^2 = 0.2619$) of Thursday are also better to forecast RV_GBP. However, one-month maturity IV_GBP outperforms two-month and three-month maturity IV_GBP in forecasting RV_GBP. Further, one-month maturity IV_GBP ($R^2 = 0.2890$) of Wednesday performs better to forecast RV_GBP for the midday period. However, one-month maturity IV_GBP ($R^2 = 0.3865$) of Thursday is superior to forecast RV_GBP for the closing period.

Table 4.13: IV_GBP forecast RV_GBP for within-week forecast horizon

Notes: This table presents the performance of IV_GBP to forecast RV_GBP for the within-week forecast horizon. Hypothesis 1, hypothesis 2, and hypothesis 3 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_GBP and RV_GBP represent the implied volatility of British Pound options and the realized volatility of the British Pound, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_GBP during the opening period) that leading to better performance of IV_GBP to forecast RV_GBP.

Table 4.14 explains the performance of IV_GBP to forecast RV_GBP for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_GBP ($R^2 = 0.4374$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_GBP at the corresponding time on Monday of the next week. The two-month maturity IV_GBP ($R^2 = 0.3897$) and three-month maturity IV_GBP ($R^2 = 0.3484$) of Monday are also better to forecast RV_GBP. However, one-month maturity IV_GBP outperforms two-month and three-month maturity IV_GBP in forecasting RV_GBP. Further, one-month maturity IV_GBP ($R^2 = 0.4271$) of Tuesday performs better to forecast RV_GBP for the midday period. However, one-month maturity IV_GBP ($R^2 = 0.4442$) of Monday is superior to forecast RV_GBP for the closing period.

Table 4.14: IV_GBP forecast RV_GBP for one-week forecast horizon

Forecast Horizon	One-month maturity IV_GBP (hypothesis 4)			Two-month maturity IV_GBP (hypothesis 5)			Three-month maturity IV_GBP (hypothesis 6)		
	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²	Intercept (P-value)	Slope (P-value)	R ²

Notes: This table explains the performance of IV_GBP to forecast RV_GBP for the one-week forecast horizon. Hypothesis 4, hypothesis 5, and hypothesis 6 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_GBP and RV_GBP represent the implied volatility of British Pound options and the realized volatility of the British Pound, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_GBP during the opening period) that leading to better performance of IV_GBP to forecast RV_GBP.

Table 4.15 shows the performance of IV_GBP to forecast RV_GBP for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. For the opening period, one-month maturity IV_GBP ($R^2 = 0.2653$) of Monday performs better than that of Tuesday, Wednesday, Thursday, and Friday to forecast RV_GBP at the corresponding time on Monday of the next month. The two-month maturity IV_GBP ($R^2 = 0.3899$) and three-month maturity IV_GBP ($R^2 = 0.3594$) of Monday are also superior to forecast RV_GBP. However, two-month maturity IV_GBP outperforms one-month and three-month maturity IV_GBP in forecasting RV_GBP. Similarly, two-month maturity IV_GBP ($R^2 = 0.3185$) of Monday performs better to forecast RV_GBP for the midday period. The two-month maturity IV_GBP ($R^2 = 0.3967$) of Monday is also superior to forecast RV_GBP for the closing period.

Table 4.15: IV_GBP forecast RV_GBP for one-month forecast horizon

Forecast Horizon	One-month maturity IV_GBP (hypothesis 7)			Two-month maturity IV_GBP (hypothesis 8)			Three-month maturity IV_GBP (hypothesis 9)

Notes: This table shows the performance of IV_GBP to forecast RV_GBP for the one-month forecast horizon. Hypothesis 7, hypothesis 8, and hypothesis 9 are tested for the opening, midday, and closing period, and results are given in panels A, B, and C, respectively. IV_GBP and RV_GBP represent the implied volatility of British Pound options and the realized volatility of the British Pound, respectively.

The intercept and slope coefficient of the regression equation (3.12) with p-value in the parenthesis and R² are reported. The p-value of 0000 in the parenthesis, indicating that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one.

* denotes a higher value of R² for each situation (e.g., one-month maturity IV_GBP during the opening period) that leading to better performance of IV_GBP to forecast RV_GBP.

4.5 Conclusion

This chapter presents the empirical analysis of the performance of IV to forecast the RV of the underlying currency of options through testing hypothesis 01 to hypothesis 09. The empirical analysis includes: estimating the IV based on the ATM price of call and put options with one-month, two-month and three-month maturity during the opening, midday, and closing period of a trading day; estimating the RV and using it as the proxy for the actual volatility; and assessing the performance of IV to forecast RV of underlying currency of options for the within-week, one-week, and one-month forecast horizon. The MZ regression is conducted based on the 630 sets of PCPs evaluating the performance of IV to forecast RV. The p-value (0000) of slope from regression stated that the null hypothesis is rejected at any level of significance. It implies that the slope coefficient is other than zero and one. Therefore, the coefficient of IV suggests it carry information content and has the explanatory power of the RV. It indicates that the IV with different options maturity subsumes the relevant information of underlying currency volatility for different forecast horizons.

Further, the R^2 (goodness-of-fit) of regression analysis measures the predictive power of the IV and the higher R^2 leading to the superior performance of IV to forecast RV. After considering higher R^2 from 630 regression analysis for the different forecast horizons, the overall findings are divided into three groups. First, for the within-week forecast horizon, two-month maturity closing period IV_AUD of Monday, IV_CAD, and IV_EUR of Tuesday, and one-month maturity closing period IV_CHF and IV_GBP of Thursday perform better to forecast RV_AUD, RV_CAD, RV_EUR, RV_CHF, and RV_GBP, respectively. It indicates that the IV obtained from the early of a week (Monday or Tuesday) and later of a week (Thursday) content relevant information to forecast RV for the within-week forecast horizon. Second, for the one-week forecast horizon, one-month maturity closing period IV_AUD, IV_CAD, IV_EUR, and IV_GBP of Monday, and IV_CHF of Tuesday is superior to forecast RV_AUD, RV_CAD, RV_EUR, RV_GBP, and RV_CHF, respectively. It suggests that the IV estimated in the early of a week (Monday or Tuesday) holds appropriate information to forecast RV for the one-week forecast horizon. Third, for the one-month forecast horizon, two-month maturity closing period IV_EUR and IV_GBP of Monday, and IV_AUD, IV_CAD, and IV_CHF of Tuesday perform better to forecast RV_EUR, RV_GBP, RV_AUD, RV_CAD, RV_CHF, respectively. It proves that the information content embedded in IV from early of a week (Monday or Tuesday) is informative to forecast RV for the one-month forecast horizon.

CHAPTER 5

Implied Volatility Estimating Currency Options Price

5.1 Introduction

This chapter conducts empirical analysis in two steps for testing hypothesis 10 to hypothesis 18 through the methodology developed in chapter 3. First, calculate the call options model price (CMOD) and put options model price (PMOD) using the ATM one-month, two-month, and three-month maturity IV obtained during the opening, midday, and closing period of a trading day as input for BS options pricing model. Second, estimate the options model pricing error by comparing the CMOD and PMOD with the call and put options market price, respectively, to evaluate the performance of IV for pricing currency options accurately, for the within-week, one-week, and one-month estimate horizon. Further, the within-week estimate horizon indicates that the IV is estimated one day to four days before the date of pricing currency options. Similarly, the one-week and one-month estimate horizon imply that the IV is estimated one-week and one-month before the date of pricing currency options, respectively.

5.2 Calculate options model price

In this section, the call and put options model prices are calculated for the within-week, one-week, and one-month estimate horizon. For the within-week estimate horizon, the appendix Table A5.1a describes the data of AUD options to compute the call options model price (AUDC_MOD) and put options model price (AUDP_MOD) employing one-month maturity IV_AUD. In column 13, the IV_AUD is calculated as in the equation (3.7), and section 4.2 discusses the calculation details. The IV_AUD of Monday, Tuesday, Wednesday, and Thursday is used as input for the equation (3.13) to estimate AUDC_MOD in column 17 at the corresponding time on Friday in the same week for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the IV_AUD of Monday, Tuesday, Wednesday, and Thursday is employed as input for the equation (3.14) to estimate AUDP_MOD in column 18 at the corresponding time on Friday in the same week for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.1b and A5.1c present the details of AUD options data for two-month and three-month maturity IV_AUD, respectively, to estimate AUDC_MOD and AUDP_MOD. Similarly, one-month, two-month and three-month maturity IV is employed to compute the model price of CAD options (appendix Tables A5.4a, A5.4b, and A5.4c), CHF options (appendix Tables A5.7a, A5.7b, and A5.7c), EUR options (appendix Tables A5.10a, A5.10b, and A5.10c), and GBP options (appendix Tables A5.13a, A5.13b, and A5.13c) are described.

For the one-week estimate horizon, the appendix Table A5.2a describes the data of AUD options to estimate AUDC_MOD and AUDP_MOD using one-month maturity IV_AUD. In column 13, the IV_AUD is computed as in the equation (3.7), and section 4.2 discusses the calculation details. The IV_AUD of Monday, Tuesday, Wednesday, Thursday, and Friday is employed as input for the equation (3.13) to calculate AUDC_MOD in column 17 at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next week, respectively, for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the IV_AUD of Monday, Tuesday, Wednesday, Thursday, and Friday is used as input for the equation (3.14) to calculate AUDP_MOD in column 18 at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next week, respectively, for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.2b and A5.2c show the details of AUD options

data for two-month and three-month maturity IV_AUD , respectively, to estimate $AUDC_MOD$ and $AUDP_MOD$. Similarly, one-month, two-month and three-month maturity IV is used to estimate model price for the CAD options (appendix Tables A5.5a, A5.5b, and A5.5c), CHF options (appendix Tables A5.8a, A5.8b, and A5.8c), EUR options (appendix Tables A5.11a, A5.11b, and A5.11c), and GBP options (appendix Tables A5.14a, A5.14b, and A5.14c) are explained.

For the one-month estimate horizon, the appendix Table A5.3a explains the data of AUD options to estimate $AUDC_MOD$ and $AUDP_MOD$ using one-month maturity IV_AUD . In column 13, the IV_AUD is calculated as in the equation (3.7), and section 4.2 discusses the calculation details. The IV_AUD of Monday, Tuesday, Wednesday, Thursday, and Friday is used as input for the equation (3.13) to calculate $AUDC_MOD$ in column 17 at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next month, respectively, for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the IV_AUD of Monday, Tuesday, Wednesday, Thursday, and Friday is used as input for the equation (3.14) to compute $AUDP_MOD$ in column 18 at the corresponding time on Monday, Tuesday, Wednesday, Thursday, and Friday of the next month, respectively, for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.3b and A5.3c provide the details of AUD options data for two-month and three-month maturity IV_AUD , respectively, to calculate $AUDC_MOD$ and $AUDP_MOD$. Similarly, one-month, two-month and three-month maturity IV is employed to compute the model price for the CAD options (appendix Tables A5.6a, A5.6b, and A5.6c), CHF options (appendix Tables A5.9a, A5.9b, and A5.9c), EUR options (appendix Tables A5.12a, A5.12b, and A5.12c), and GBP options (appendix Tables A5.15a, A5.15b, and A5.15c) are explained.

5.3 Estimate options pricing error

The performance of IV to estimate currency options price is evaluated through OPE for the within-week, one-week, and one-month estimate horizon.

For within-week estimate horizon, the appendix Table A5.1a describes the data of AUD options to generate AUDC and AUDP for the one-month maturity IV_AUD. The AUDC_MOD of Friday in column 17 is compared with the call options market price (AUDC_MKT) at the corresponding time on Friday in the same week in column 19 to estimate the call OPE using MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the AUDP_MOD of Friday in column 18 comparing with the put options market price (AUDP_MKT) at the corresponding time on Friday in the same week in column 20 to estimate the put OPE using MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.1b and A5.1c present the details of AUD options for the one-month and two-month maturity IV_AUD, respectively, to estimate the call OPE and put OPE. Similarly, one-month, two-month and three-month maturity IV estimate call and put OPE for CAD options (Tables A5.4a, A5.4b, and A5.4c), CHF options (Tables A5.7a, A5.7b, and A5.7c), EUR options (Tables A5.10a, A5.10b, and A5.10c), and GBP options (Tables A5.13a, A5.13b, and A5.13c) are described.

For one-week estimate horizon, the appendix Table A5.2a explains the data of AUD options to generate AUDC and AUDP for the one-month maturity IV_AUD. The AUDC_MOD of Monday, Tuesday, Wednesday, Thursday and Friday in column 17 is compared with AUDC_MKT at the corresponding time on Monday, Tuesday, Wednesday, Thursday and Friday of the next week in column 19 to compute the call OPE under MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the AUDP_MOD of Monday, Tuesday, Wednesday, Thursday and Friday in column 18 comparing with the AUDP_MKT at the corresponding time on Monday, Tuesday, Wednesday, Thursday and Friday of the next week in column 20 to estimate the put OPE using MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.2b and A5.2c

provide the details of AUD options for the one-month and two-month maturity IV_AUD, respectively, to compute the call OPE and put OPE. Similarly, one-month, two-month and three-month maturity IV calculate call and put OPE for CAD options (Tables A5.5a, A5.5b, and A5.5c), CHF options (Tables A5.8a, A5.8b, and A5.8c), EUR options (Tables A5.11a, A5.11b, and A5.11c), and GBP options (Tables A5.14a, A5.14b, and A5.14c) are explained.

For the one-month estimate horizon, the appendix Table A5.3a describes the data of AUD options to generate AUDC and AUDP for the one-month maturity IV_AUD. The AUDC_MOD of Monday, Tuesday, Wednesday, Thursday and Friday in column 17 is compared with AUDC_MKT at the corresponding time on Monday, Tuesday, Wednesday, Thursday and Friday of the next month in column 19 to calculate the call OPE under MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Similarly, the AUDP_MOD of Monday, Tuesday, Wednesday, Thursday and Friday in column 18 is compared with the AUDP_MKT at the corresponding time on Monday, Tuesday, Wednesday, Thursday and Friday of the next month in column 20 to estimate the put OPE using MAE (equation 3.15), MSE (equation 3.16) and RMSE (equation 3.17) methods for the opening, midday, and closing period of a trading day in panels A, B, and C, respectively. Further, appendix Tables A5.3b and A5.3c provide the details of AUD options for the one-month and two-month maturity IV_AUD, respectively, to estimate the call OPE and put OPE. Similarly, one-month, two-month and three-month maturity IV estimate call and put OPE for CAD options (Tables A5.6 a, A5.6b, and A5.6c), CHF options (Tables A5.9a, A5.9b, and A5.9c), EUR options (Tables A5.12a, A5.12b, and A5.12c), and GBP options (Tables A5.15a, A5.15b, and A5.15c) are described.

5.4 Empirical analysis

The empirical analysis is conducted to estimate the currency OPE of one-month, two-month, and three-month maturity IV during the opening, midday, and closing period of a trading day for the within-week, one-week, and one-month estimate horizon. The mean absolute error (MAE), mean squared error (MSE), and root mean squared error (RMSE) methods are employed as in equation (3.15), equation (3.16), and equation (3.17), respectively, to measure OPE. Hypotheses 10 to 18 are examined through evaluating the minimum OPE for the AUD, CAD, CHF, EUR, and GBP options. Table 5.1 analyses the performance of IV_AUD to estimate AUD call (AUDC) and AUD put (AUDP) options price for the within-week estimate horizon. The hypothesis 10, hypothesis 11, and hypothesis 12 are tested for the opening, midday, and closing period of a trading day under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_AUD perform better to calculate AUDC (pricing errors = 0.1389) and AUDP (pricing errors = 0.0687) options price of Friday in the same week. Similarly, two-month maturity, Monday, and closing period IV_AUD is superior to estimate the value of AUDC (pricing error = 0.1374) and AUDP (pricing error = 0.0679) options. Further, the three-month maturity, Monday, and closing period IV_AUD outperform to compute AUDC (pricing error = 0.1397) and AUDP (pricing error = 0.0799) options price. However, two-month maturity, Monday, and closing period IV_AUD provide lower pricing error (AUDC pricing error = 0.1374 and AUDP pricing error = 0.0679) under MAE measure. Similarly, MSE measure generates lower pricing error (AUDC pricing error = 0.0361 and AUDP pricing error = 0.0091) for two-month maturity, Monday, and closing period IV_AUD. The RMSE measure also generates the lower pricing error (AUDC pricing error = 0.1901 and AUDP pricing error = 0.0954) for the two-month maturity, Monday, and closing period IV_AUD. The overall results suggest that two-month maturity, Monday, and closing period IV_AUD is superior to estimate the price of AUDC and AUDP options correctly with a minimum pricing error under all measures.

Table 5. 1: IV_AUD estimate AUD options price for within-week estimate horizon

Notes: This table analyses the performance of IV_AUD to estimate AUD call (AUDC) and AUD put (AUDP) options price for the within-week estimate horizon. The hypothesis 10, hypothesis 11, and hypothesis 12 are tested for the opening, midday, and closing period of a trading day under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

AUDC and AUDP denoting AUD call and AUD put, respectively.

* indicating minimum pricing error for AUDC options price.

** indicating minimum pricing error for AUDP options price.

Table 5.2 analyses the performance of IV_AUD to estimate AUDC and AUDP options price for the one-week estimate horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_AUD perform better to calculate AUDC (pricing errors = 0.1427) and AUDP (pricing errors = 0.0563) options price of Monday in next week. Similarly, two-month maturity, Monday, and closing period IV_AUD is superior to estimate the price of AUDC (pricing error = 0.1497) and AUDP (pricing error = 0.0617) options. Further, the three-month maturity, Monday, and closing period IV_AUD outperform to compute AUDC (pricing error = 0.1551) and AUDP (pricing error = 0.0796) options price. However, one-month maturity, Monday, and closing period IV_AUD show lower pricing error (AUDC pricing error = 0.1427 and AUDP pricing error = 0.0563) under MAE measure. Similarly, MSE measure provides lower pricing error (AUDC pricing error = 0.0441 and AUDP pricing error = 0.0074) for one-month maturity, Monday, and closing period IV_AUD. The RMSE measure also estimates the lower pricing error (AUDC pricing error = 0.2100 and AUDP pricing error = 0.0858) for the one-month maturity, Monday, and closing period IV_AUD. The overall results imply that one-month maturity, Monday, and closing period IV_AUD outperform to estimate the value of AUDC and AUDP options precisely with a minimum pricing error under all measures.

Table 5. 2: IV_AUD estimate AUD options price for one-week estimate horizon

Notes: This table analyses the performance of IV_AUD to estimate AUDC and AUDP options price for the one-week estimate horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The ‘mean absolute error’, ‘mean squared error’ and ‘root mean squared error’ denoting by MAE, MSE and RMSE, respectively.

AUDC and AUDP denoting AUD call and AUD put, respectively.

* indicating minimum pricing error for AUDC options price.

** indicating minimum pricing error for AUDP options price.

Table 5.3 analyses the performance of IV_AUD to estimate AUDC and AUDP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are given in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Tuesday, and closing period IV_AUD outperform to estimate AUDC (pricing errors = 0.1467) and AUDP (pricing errors = 0.0912) options price of Tuesday in next month. Similarly, two-month maturity, Tuesday, and closing period IV_AUD is superior to estimate AUDC (pricing error = 0.1447) and AUDP (pricing error = 0.0777) options price. Further, the three-month maturity, Tuesday, and closing period IV_AUD perform better to compute the price of AUDC (pricing error = 0.1521) and AUDP (pricing error = 0.0942) options. However, two-month maturity, Tuesday, and closing period IV_AUD show lower pricing error (AUDC pricing error = 0.1447 and AUDP pricing error = 0.0777) under MAE measure. Similarly, MSE measure generates lower pricing error (AUDC pricing error = 0.0431 and AUDP pricing error = 0.0128) for two-month maturity, Tuesday, and closing period IV_AUD. The RMSE measure also estimates the lower pricing error (AUDC pricing error = 0.2076 and AUDP pricing error = 0.1132) for the two-month maturity, Tuesday, and closing period IV_AUD. The overall results indicate that two-month maturity, Tuesday, and closing period IV_AUD better to estimate AUDC and AUDP options price accurately with a minimum pricing error under all measures.

Table 5. 3: IV_AUD estimate AUD options price for one-month estimate horizon

Notes: This table analyses the performance of IV_AUD to estimate AUDC and AUDP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are given in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

AUDC and AUDP denoting AUD call and AUD put, respectively.

* indicating minimum pricing error for AUDC options price.

** indicating minimum pricing error for AUDP options price.

Table 5.4 analyses the performance of IV_CAD to estimate CAD call (CADC) and CAD put (CADP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Thursday, and closing period IV_CAD superior to estimate the value of CADC (pricing errors = 0.1247) and CADP (pricing errors = 0.0569) options of Friday in the same week. Similarly, two-month maturity, Thursday, and closing period IV_CAD outperform to the value of CADC (pricing error = 0.1334) and CADP (pricing error = 0.0597) options. Further, the three-month maturity, Thursday, and closing period IV_CAD is superior to compute CADC (pricing error = 0.1389) and CADP (pricing error = 0.0652) options price. However, one-month maturity, Thursday, and closing period IV_CAD provide lower pricing error (CADC pricing error = 0.1247 and CADP pricing error = 0.0569) under MAE measure. Similarly, MSE measure generates lower pricing error (CADC pricing error = 0.0310 and CADP pricing error = 0.0062) for one-month maturity, Thursday, and closing period IV_CAD. The RMSE measure also estimates the lower pricing error (CADC pricing error = 0.1762 and CADP pricing error = 0.0789) for the one-month maturity, Thursday, and closing period IV_CAD. The overall results imply that one-month maturity, Thursday, and closing period IV_CAD outperform to estimate CADC and CADP options price correctly with a minimum pricing error under all measures.

Table 5. 4: IV_CAD estimate CAD options price for within-week estimate horizon

Notes: This table analyses the performance of IV_CAD to estimate CAD call (CADC) and CAD put (CADP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

CADC and CADP denoting CAD call and CAD put, respectively.

* indicating minimum pricing error for CADC options price.

** indicating minimum pricing error for CADP options price.

Table 5.5 analyses the performance of IV_CAD to estimate CADC and CADP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_CAD outperform to compute the value of CADC (pricing errors = 0.1136) and CADP (pricing errors = 0.0551) options of Monday in next week. Similarly, two-month maturity, Monday, and closing period IV_CAD is better to estimate the price of CADC (pricing error = 0.1186) and CADP (pricing error = 0.0573) options. Further, the three-month maturity, Monday, and closing period IV_CAD outperform to calculate CADC (pricing error = 0.1372) and CADP (pricing error = 0.0599) options price. However, one-month maturity, Monday, and closing period IV_CAD provide lower pricing error (CADC pricing error = 0.1136 and CADP pricing error = 0.0551) under MAE measure. Similarly, MSE measure generates lower pricing error (CADC pricing error = 0.0236 and CADP pricing error = 0.0061) for one-month maturity, Monday, and closing period IV_CAD. The RMSE measure also computes the lower pricing error (CADC pricing error = 0.1417 and CADP pricing error = 0.0778) for the one-month maturity, Monday, and closing period IV_CAD. The overall results suggest that one-month maturity, Monday, and closing period IV_CAD perform better to estimate the value of CADC and CADP options precisely with a minimum pricing error under all measures.

Table 5. 5: IV_CAD estimate CAD options price for one-week estimate horizon

Notes: This table analyses the performance of IV_CAD to estimate CADC and CADP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

CADC and CADP denoting CAD call and CAD put, respectively.

* indicating minimum pricing error for CADC options price.

** indicating minimum pricing error for CADP options price.

Table 5.6 analyses the performance of IV_CAD to estimate CADC and CADP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Tuesday, and closing period IV_CAD outperform to calculate CADC (pricing errors = 0.1201) and CADP (pricing errors = 0.0709) options price of Tuesday in next month. Similarly, two-month maturity, Tuesday, and closing period IV_CAD is superior to estimate the price of CADC (pricing error = 0.1197) and CADP (pricing error = 0.0649) options. Further, the three-month maturity, Tuesday, and closing period IV_CAD is better to estimate CADC (pricing error = 0.1342) and CADP (pricing error = 0.0691) options price. However, two-month maturity, Tuesday, and closing period IV_CAD show lower pricing error (CADC pricing error = 0.1197 and CADP pricing error = 0.0649) under MAE measure. Similarly, MSE measure provides lower pricing error (CADC pricing error = 0.0273 and CADP pricing error = 0.0103) for two-month maturity, Tuesday, and closing period IV_CAD. The RMSE measure also generates the lower pricing error (CADC pricing error = 0.1651 and CADP pricing error = 0.1014) for the two-month maturity, Tuesday, and closing period IV_CAD. The overall results indicate that two-month maturity, Tuesday, and closing period IV_CAD outperform to calculate the value of CADC and CADP options precisely with a minimum pricing error under all measures.

Notes: This table analyses the performance of IV_CAD to estimate CADC and CADP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively. The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively. CADC and CADP denoting CAD call and CAD put, respectively.

* indicating minimum pricing error for CADC options price.

** indicating minimum pricing error for CADP options price.

Table 5.7 analyses the performance of IV_CHF to estimate CHF call (CHFC) and CHF put (CHFP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_CHF perform better to compute CHFC (pricing errors = 0.1792) and CHFP (pricing errors = 0.0945) options price of Friday in the same week. Similarly, two-month maturity, Monday, and closing period IV_CHF is superior to calculate the value of CHFC (pricing error = 0.1744) and CHFP (pricing error = 0.0902) options. Further, the three-month maturity, Monday, and closing period IV_CHF outperform to estimate CHFC (pricing error = 0.2110) and CHFP (pricing error = 0.1060) options price. However, two-month maturity, Monday, and closing period IV_CHF generate lower pricing error (CHFC pricing error = 0.1744 and CHFP pricing error = 0.0902) under MAE measure. Similarly, MSE measure shows lower pricing error (CHFC pricing error = 0.0749 and CHFP pricing error = 0.0154) for two-month maturity, Monday, and closing period IV_CHF. The RMSE measure also estimates the lower pricing error (CHFC pricing error = 0.2737 and CHFP pricing error = 0.1240) for the two-month maturity, Monday, and closing period IV_CHF. The overall results imply that two-month maturity, Monday, and closing period IV_CHF superior to compute the value of CHFC and CHFP options correctly with a minimum pricing error under all measures.

Table 5. 7: IV_CHF estimate CHF options price for within-week estimate horizon

Notes: This table analyses the performance of IV_CHF to estimate CHF call (CHFC) and CHF put (CHFP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively. CHFC and CHFP denoting CHF call and CHF put, respectively.

* indicating minimum pricing error for CHFC options price.

** indicating minimum pricing error for CHFP options price.

Table 5.8 analyses the performance of IV_CHF to estimate CHFC and CHFP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_CHF perform better to estimate the value of CHFC (pricing errors = 0.1385) and CHFP (pricing errors = 0.0838) options of Monday in next week. Similarly, two-month maturity, Monday, and closing period IV_CHF outperform to compute CHFC (pricing error = 0.1646) and CHFP (pricing error = 0.0965) options price. Further, the three-month maturity, Monday, and closing period IV_CHF is superior to calculate the price of CHFC (pricing error = 0.1679) and CHFP (pricing error = 0.1060) options, However, one-month maturity, Monday, and closing period IV_CHF show lower pricing error (CHFC pricing error = 0.1385 and CHFP pricing error = 0.0838) under MAE measure. Similarly, MSE measure shows lower pricing error (CHFC pricing error = 0.0358 and CHFP pricing error = 0.0170) for one-month maturity, Monday, and closing period IV_CHF. The RMSE measure also estimates the lower pricing error (CHFC pricing error = 0.1893 and CHFP pricing error = 0.1303) for the one-month maturity, Monday, and closing period IV_CHF. The overall results indicate that one-month maturity, Monday, and closing period IV_CHF outperform to estimate CHFC and CHFP options price precisely with a minimum pricing error under all measures.

Table 5. 8: IV_CHF estimate CHF options price for one-week estimate horizon

Horizon	Options	One-month maturity			Two-month maturity			Three-month Maturity

Notes: This table analyses the performance of IV_CHF to estimate CHFC and CHFP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively.OP, MD and CL denoting opening period, midday period and closing period, respectively.

The ‘mean absolute error’, ‘mean squared error’ and ‘root mean squared error’ denoting by MAE, MSE and RMSE, respectively.

CHFC and CHFP denoting CHF call and CHF put, respectively.

* indicating minimum pricing error for CHFC options price.

** indicating minimum pricing error for CHFP options price.

Table 5.9 analyses the performance of IV_CHF to estimate CHFC and CHFP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Tuesday, and closing period IV_CHF better to estimate CHFC (pricing errors = 0.1625) and CHFP (pricing errors = 0.1425) options price of Tuesday in next month. Similarly, two-month maturity, Tuesday, and closing period IV_CHF is superior to calculate CHFC (pricing error = 0.1576) and CHFP (pricing error = 0.1308) options price. Further, the three-month maturity, Tuesday, and closing period IV_CHF outperform to estimate the value of CHFC (pricing error = 0.1891) and CHFP (pricing error = 0.1442) options. However, two-month maturity, Tuesday, and closing period IV_CHF provide lower pricing error (CHFC pricing error = 0.1576 and CHFP pricing error = 0.1308) under MAE measure. Similarly, MSE measure provides lower pricing error (CHFC pricing error = 0.0482 and CHFP pricing error = 0.0330) for two-month maturity, Tuesday, and closing period IV_CHF. The RMSE measure also estimates the lower pricing error (CHFC pricing error = 0.2195 and CHFP pricing error = 0.1817) for the two-month maturity, Tuesday, and closing period IV_CHF. The overall results suggest that two-month maturity, Tuesday, and closing period IV_CHF outperform to calculate CHFC and CHFP options price accurately with a minimum pricing error under all measures.

Table 5. 9: IV_CHF estimate CHF options price for one-month estimate horizon

Notes: This table analyses the performance of IV_CHF to estimate CHFC and CHFP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively. The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively. CHFC and CHFP denoting CHF call and CHF put, respectively.

* indicating minimum pricing error for CHFC options price.

** indicating minimum pricing error for CHFP options price.

Table 5.10 analyses the performance of IV_EUR to estimate EUR call (EURC) and EUR put (EURP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_EUR outperform to calculate EURC (pricing errors = 0.1761) and EURP (pricing errors = 0.1021) options price of Friday in the same week. Similarly, two-month maturity, Monday, and closing period IV_EURF is superior to estimate the value of EURC (pricing error = 0.1736) and EURP (pricing error = 0.0830) options. Further, the three-month maturity, Monday, and closing period IV_EUR superior to compute the value of EURC (pricing error = 0.2326) and EURP (pricing error = 0.1302) options. However, two-month maturity, Monday, and closing period IV_EUR generate lower pricing error (EURC pricing error = 0.1736 and EURP pricing error = 0.0830) under MAE measure. Similarly, MSE measure generates lower pricing error (EURC pricing error = 0.0595 and EURP pricing error = 0.0219) for two-month maturity, Monday, and closing period IV_EUR. The RMSE measure also estimates the lower pricing error (EURC pricing error = 0.2439 and EURP pricing error = 0.1481) for the two-month maturity, Monday, and closing period IV_EUR. The overall results indicate that two-month maturity, Monday, and closing period IV_EUR better to estimate the price of EURC and EURP options precisely with a minimum pricing error under all measures.

Table 5. 10: IV_EUR estimate EUR options price for within-week estimate horizon

Notes: This table analyses the performance of IV_EUR to estimate EUR call (EURC) and EUR put (EURP) options price for the within-week horizon. The hypothesis10, hypothesis11, and hypothesis12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

EURC and EURP denoting EUR call and EUR put, respectively.

* indicating minimum pricing error for EURC options price.

** indicating minimum pricing error for EURP options price.

Table 5.11 analyses the performance of IV_EUR to estimate EURC and EURP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_EUR is superior to compute the price of EURC (pricing errors = 0.1798) and EURP (pricing errors = 0.0746) options of Monday in next week. Similarly, two-month maturity, Monday, and closing period IV_EUR outperform to estimate the value of EURC (pricing error = 0.1826) and EURP (pricing error = 0.0821) options price. Further, the three-month maturity, Monday, and closing period IV_EUR outperform to estimate EURC (pricing error = 0.1848) and EURP (pricing error = 0.1013) options price. However, one-month maturity, Monday, and closing period IV_EUR generate lower pricing error (EURC pricing error = 0.1798 and EURP pricing error = 0.0746) under MAE measure. Similarly, MSE measure provides lower pricing error (EURC pricing error = 0.0658 and EURP pricing error = 0.0121) for one-month maturity, Monday, and closing period IV_EUR. The RMSE measure also generates the lower pricing error (EURC pricing error = 0.2565 and EURP pricing error = 0.1101) for the one-month maturity, Monday, and closing period IV_EUR. The overall results imply that one-month maturity, Monday, and closing period IV_EUR outperform to estimate the price of EURC and EURP options correctly with a minimum pricing error under all measures.

Table 5. 11: IV_EUR estimate EUR options price for one-week estimate horizon

Horizon	Options	One-month maturity			Two-month maturity IV_EUR			Three-month Maturity

Notes: This table analyses the performance of IV_EUR to estimate EURC and EURP options price for the one-week horizon. The hypothesis13, hypothesis14, and hypothesis15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively. The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively. EURC and EURP denoting EUR call and EUR put, respectively.

* indicating minimum pricing error for EURC options price.

** indicating minimum pricing error for EURP options price.

Table 5.12 analyses the performance of IV_EUR to estimate EURC and EURP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Tuesday, and closing period IV_EUR better to estimate the price of EURC (pricing errors = 0.2065) and EURP (pricing errors = 0.1094) options of Tuesday in next month. Similarly, two-month maturity, Tuesday, and closing period IV_EUR is superior to estimate EURC (pricing error = 0.1965) and EURP (pricing error = 0.0994) options price. Further, the three-month maturity, Tuesday, and closing period IV_EUR outperform to estimate the value of EURC (pricing error = 0.2063) and EURP (pricing error = 0.1224) options price. However, two-month maturity, Tuesday, and closing period IV_EUR provide lower pricing error (EURC pricing error = 0.1965 and EURP pricing error = 0.0994) under MAE measure. Similarly, MSE measure generates lower pricing error (EURC pricing error = 0.0760 and EURP pricing error = 0.0219) for two-month maturity, Tuesday, and closing period IV_EUR. The RMSE measure also estimates the lower pricing error (EURC pricing error = 0.2757 and EURP pricing error = 0.1480) for the two-month maturity, Tuesday, and closing period IV_EUR. The overall results indicate that two-month maturity, Tuesday, and closing period IV_EUR superior to estimate the value of EURC and EURP options precisely with a minimum pricing error under all measures.

Table 5. 12: IV_EUR estimate EUR options price for one-month estimate horizon

Notes: This table analyses the performance of IV_EUR to estimate EURC and EURP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively. EURC and EURP denoting EUR call and EUR put, respectively.

* indicating minimum pricing error for EURC options price.

** indicating minimum pricing error for EURP options price.

Table 5.13 analyses the performance of IV_GBP to estimate GBP call (GBPC) and GBP put (GBPP) options price for the within-week horizon. The hypothesis 10, hypothesis 11, and hypothesis 12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Thursday, and closing period IV_GBP perform better to compute GBPC (pricing errors = 0.0762) and GBPP (pricing errors = 0.0914) options price of Friday in the same week. Similarly, two-month maturity, Thursday, and closing period IV_GBP outperform to estimate GBPC (pricing error = 0.1985) and GBPP (pricing error = 0.0954) options price. Further, the three-month maturity, Thursday, and closing period IV_GBP is superior to calculate GBPC (pricing error = 0.2010) and GBPP (pricing error = 0.1051) options price. However, one-month maturity, Thursday, and closing period IV_GBP provide lower pricing error (GBPC pricing error = 0.0762 and GBPP pricing error = 0.0914) under MAE measure. Similarly, MSE measure provides lower pricing error GBPC (pricing error = 0.0314 and GBPP pricing error = 0.0201) for one-month maturity, Thursday, and closing period IV_GBP. The RMSE measure also generates the lower pricing error (GBPC pricing error = 0.2670 and GBPP pricing error = 0.1417) for the one-month maturity, Thursday, and closing period IV_GBP. The overall results suggest that one-month maturity, Thursday, and closing period IV_GBP outperform to estimate GBPC and GBPP options price precise with a minimum pricing error under all measures.

Table 5. 13: IV_ GBP estimate GBP options price for within-week estimate horizon

Notes: This table analyses the performance of IV_GBP to estimate GBP call (GBPC) and GBP put (GBPP) options price for the within-week horizon. The hypothesis 10, hypothesis 11, and hypothesis 12 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively.

The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

GBPC and GBPP denoting GBP call and GBP put, respectively.

* indicating minimum pricing error for GBPC options price.

** indicating minimum pricing error for GBPP options price.

Table 5.14 analyses the performance of IV_GBP to estimate GBPC and GBPP options price for the one-week horizon. The hypothesis 13, hypothesis 14, and hypothesis 15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Monday, and closing period IV_GBP outperform to estimate the value of GBPC (pricing errors = 0.1987) and GBPP (pricing errors = 0.0899) options of Monday in next week. Similarly, two-month maturity, Monday, and closing period IV_GBP is better to compute GBPC (pricing error = 0.2000) and GBPP (pricing error = 0.1010) options price. Further, the three-month maturity, Monday, and closing period IV_GBP is superior to estimate GBPC (pricing error = 0.2012) and GBPP (pricing error = 0.1112) options price. However, one-month maturity, Monday, and closing period IV_GBP provide lower pricing error (GBPC pricing error = 0.1987 and GBPP pricing error = 0.0899) under MAE measure. Similarly, MSE measure generates lower pricing error (GBPC pricing error = 0.0616 and GBPP pricing error = 0.0172) for one-month maturity, Monday, and closing period IV_GBP. The RMSE measure also estimates the lower pricing error (GBPC pricing error = 0.2556 and GBPP pricing error = 0.1311) for the one-month maturity, Monday, and closing period IV_GBP. The overall results imply that one-month maturity, Monday, and closing period IV_GBP outperform to estimate the value of GBPC and GBPP options price precisely with a minimum pricing under all measures.

Table 5. 14: IV_GBP estimate GBP options price for one-week estimate horizon

Notes: This table analyses the performance of IV_GBP to estimate GBPC and GBPP options price for the one-week horizon. The hypothesis 13, hypothesis 14, and hypothesis 15 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively. The 'mean absolute error', 'mean squared error' and 'root mean squared error' denoting by MAE, MSE and RMSE, respectively.

GBPC and GBPP denoting GBP call and GBP put, respectively.

* indicating minimum pricing error for GBPC options price.

** indicating minimum pricing error for GBPP options price.

Table 5.15 analyses the performance of IV_GBP to estimate GBPC and GBPP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. For MAE measure, one-month maturity, Tuesday, and closing period IV_GBP perform better to estimate GBPC (pricing errors = 0.1908) and GBPP (pricing errors = 0.1261) options price of Tuesday in next month. Similarly, two-month maturity, Tuesday, and closing period IV_GBP is superior to estimate the value of GBPC (pricing error = 0.1898) and GBPP (pricing error = 0.1161) options. Further, the three-month maturity, Tuesday, and closing period IV_GBP outperform to compute GBPC (pricing error = 0.2308) and GBPP (pricing error = 0.1388) options price. However, two-month maturity, Tuesday, and closing period IV_GBP show lower pricing error (GBPC pricing error = 0.1898 and GBPP pricing error = 0.1161) under MAE measure. Similarly, MSE measure generates lower pricing error (GBPC pricing error = 0.0714 and GBPP pricing error = 0.0322) for two-month maturity, Tuesday, and closing period IV_GBP. The RMSE measure also estimates the lower pricing error (GBPC pricing error = 0.2672 and GBPP pricing error = 0.1794) for the two-month maturity, Tuesday, and closing period IV_GBP. The overall results indicate that two-month maturity, Tuesday, and closing period IV_GBP superior to estimate GBPC and GBPP options price correctly with a minimum pricing error under all measures.

Table 5. 15: IV_GBP estimate GBP options price for one-month estimate horizon

Notes: This table analyses the performance of IV_GBP to estimate GBPC and GBPP options price for the one-month horizon. The hypothesis 16, hypothesis 17, and hypothesis 18 are tested for the opening period, midday period, and closing period under MAE, MSE and RMSE measures and results are reported in the panels A, B, and C, respectively. OP, MD and CL denoting opening period, midday period and closing period, respectively. The ‘mean absolute error’, ‘mean squared error’ and ‘root mean squared error’ denoting by MAE, MSE and RMSE, respectively.

GBPC and GBPP denoting GBP call and GBP put, respectively.

* indicating minimum pricing error for GBPC options price.

** indicating minimum pricing error for GBPP options price.

5.5 Conclusion

This chapter presents the empirical analysis for evaluating the performance of IV to estimate the call and put options price through testing hypothesis 10 to hypothesis 18. The empirical analysis includes: calculating the CMOD and PMOD using the ATM one-month, two-month, and three-month maturity IV obtained during the opening, midday, and closing period of a trading day as input for BS options pricing model; and estimating the OPE by comparing the CMOD and PMOD with the call and put options market price, respectively. The MAE, MSE, and RMSE measures estimate the call and put OPEs employing 1260 sets (630 sets for each call and put options) of options model price and options market price for the within-week, one-week, and one-month estimate horizon.

After considering the minimum call and put OPE, this chapter presents three groups of findings. First, for the within-week estimate horizon, two-month maturity closing period IV_AUD, IV_CHF, and IV_EUR of Monday is superior to generate the call and put OPE for AUD, CHF, and EUR options, respectively, under all measures. Further, the one-month maturity closing period IV_CAD and IV_GBP of Thursday is significant to estimate the call and put OPE for CAD and GBP options, respectively, under all measures. It indicates that the two-month maturity IV from early of a week (Monday or Tuesday) and one-month maturity IV from later of a week (Thursday) in the closing trading period contain relevant information to calculate the value of currency options for the within-week estimate horizon. Second, for the one-week estimate horizon, one-month maturity closing period IV_AUD, IV_CAD, IV_CHF, IV_EUR, and IV_GBP of Monday is superior to estimate the call and put OPE for AUD, CAD, CHF, EUR, GBP options, respectively, under all measures. It reveals that the one-month maturity IV from early of a week (Monday or Tuesday) in the closing trading period holds appropriate information to price currency options price for the one-week estimate horizon. Third, for the one-month estimate horizon, two-month maturity closing period IV_AUD, IV_CAD, IV_CHF, IV_EUR, and IV_GBP of Tuesday is excellent to generate the call and put OPE for AUD, CAD, CHF, EUR, GBP options, respectively, under all measures. It suggests that the two-month maturity IV from early of a week (Monday or Tuesday) in the closing trading period subsumes vital information to compute the value of currency options for the one-month estimate horizon.

CHAPTER 6

Conclusion of Thesis

6.1 Introduction

The empirical analysis is conducted for testing hypotheses 01 to 09 and hypotheses 10 to 18 in chapters 4 and 5, respectively, and a summary of the results is discussed in this chapter to conclude the thesis. The empirical findings in chapter 4 based on the analysis (i) IV forecast RV for the underlying currency of options for the within-week horizon, (ii) IV forecast RV for the underlying currency of options for the one-week horizon, and (iii) IV forecast RV for the underlying currency of options for the one-month horizon. Further, chapter 5 provides empirical results based on the analysis (i) IV estimate currency options price for the within-week estimate horizon, (ii) IV estimate currency options price for the one-week estimate horizon, and (iii) IV estimate currency options price for the one-month estimate horizon. This chapter also includes research significance, research limitations, and recommendations for future research.

6.2 Research findings

Table 6.1 is developed based on the empirical findings from chapter 4. The significant results from the analysis of IV forecast RV of underlying currency of options for the within-week horizon in Tables 4.1, 4.4, 4.7, 4.10, and 4.13 for AUD, CAD, CHF, EUR, and GBP, respectively, are reproduced in panel A. For example, the R^2 values 0.3362, 0.2809, and 0.3796 reported in column 5 are obtained from Table 4.1 for two-month maturity IV in the opening, midday, and closing period, respectively. Similarly, the key empirical results based on the analysis of IV forecast RV of underlying currency for the one-week horizon in Tables 4.2, 4.5, 4.8, 4.11, and 4.14 for AUD, CAD, CHF, EUR, and GBP, respectively, are presented in panel B. Further, the key findings from the investigation of IV forecast RV of underlying currency for the one-month horizon in Tables 4.3, 4.6, 4.9, 4.12, and 4.15 for AUD, CAD, CHF, EUR, and GBP, respectively, are given in panel C.

In Panel A for IV_AUD, the higher value of R^2 (0.3796) indicates that the 2-month maturity, Monday (begin-week day), and closing period IV is superior to forecast RV_AUD, which is reported in column 6. Similarly, a summary of the results from the analysis of IV to forecast RV with a higher value of R^2 for each currency is given in column 6. The overall mixed results leading to two critical findings in the last column: (i) two-month maturity, begin-week day, and closing period IV_AUD, IV_CAD, and IV_EUR are superior to forecast RV_AUD, RV_CAD, and RV_EUR for within-week forecast horizon, and (ii) one-month maturity, end-week day, and closing period IV_CHF and IV_GBP are superior to forecast RV_CHF and RV_GBP for within-week forecast horizon. In panel B, column 6 provides consistent results for all currencies with a critical finding in the last column that 1-month maturity, begin-week day, and closing period IV is superior to forecast RV of all underlying currency for the one-week forecast horizon. Finally, panel C reported consistent results for underlying currency in column 6 and provided a significant finding in the last column that two-month maturity, begin-week day, and closing period IV is superior to forecast RV of all underlying currency for one-month forecast horizon.

Table 6.1: Analysis IV to forecast RV of currency for different forecast horizons

Notes: This table is developed based on the empirical findings from chapter 4. The significant results from the analysis of IV forecast RV of underlying currency of options for the within-week horizon in Tables 4.1, 4.4, 4.7, 4.10, and 4.13 for AUD, CAD, CHF, EUR, and GBP, respectively, are reproduced in panel A. Monday and Tuesday, Wednesday, and Thursday and Friday are begin-week day, mid-week day, and end-week day, respectively. 9.30 to 10.00, 12.30 to 13.00, and 15.30 to 16.00 are opening, midday, and closing period, respectively.

* denotes higher value of R² among opening, midday, and closing period that is leading to the performance of IV to forecast RV.

Table 6.2 is constructed with the critical findings of empirical analysis in chapter 5. The results of minimum pricing error analysis are consistent under all measures for all currency options price in chapter 5. However, we have reproduced the minimum pricing error only under the MSE measure in Table 6.2 for illustration purposes. The minimum pricing error from the analysis of IV estimating the price of AUD, CAD, CHF, EUR, and GBP options for the within-week horizon in Tables 5.1, 5.4, 5.7, 5.10, and 5.13 respectively, are reported in Panel A. For example, the minimum pricing errors 0.0361 and 0.0091 for AUDC and AUDP, respectively, are obtained from Table 5.1 for two-month maturity, Monday, and closing period IV under MSE measure, reported in column 6. Similarly, the minimum pricing error from the investigation of IV estimating the price of AUD, CAD, CHF, EUR, and GBP options for the one-week horizon in Tables 5.2, 5.5, 5.8, 5.11, and 5.14, respectively, are given in Panel B. Further, the minimum pricing error from the analysis of IV estimating the price of AUD, CAD, CHF, EUR, and GBP options for the one-month horizon in Tables 5.3, 5.6, 5.9, 5.12, and 5.15 respectively, are presented in Panel C.

Column 7 of Table 6.2 provides a summary of the results from the analysis of IV to estimate options price with a minimum pricing error for each currency options. Panel A shows mixed results in column 7 with two critical findings in the last column. First, two-month maturity, begin-week day, and closing period IV_AUD, IV_CHF, and IV_EUR are superior to estimate the price of AUD, CHF, and EUR options, respectively, for the within-week estimate horizon. Second, one-month maturity, end-week day, and closing period IV_CAD and IV_GBP perform better to compute the value of CAD and GBP, respectively, for the within-week estimate horizon. In panel B, the overall results for all currency options are consistent in column 7 and provided a crucial finding in the last column that one-month maturity, begin-week day, and closing period IV is significant to calculate the value of all currency options for the one-week estimate horizon. Finally, panel C reported consistent results for all currency options in column 7 and provided a critical finding that two-month maturity, begin-week day, and closing period IV is appropriate to estimate the price of all currency options for the one-month estimate horizon.

Notes: This table is constructed with the critical findings of empirical analysis in chapter 5. The results of minimum pricing error analysis are consistent under all measures for all currency options price in chapter 5. However, we have reproduced the minimum pricing error only under the MSE measure in Table 6.2 for illustration purposes. Monday and Tuesday, Wednesday, and Thursday and Friday are begin-week day, mid-week day, and end-week day, respectively. 9.30 to 10.00, 12.30 to 13.00, and 15:30 to 16.00 are opening, midday, and closing period, respectively. * denotes call and put options minimum pricing error under MSE (mean squared error) measure.

The key findings in Tables 6.1 provide a mixed picture for IV of holding information to forecast RV for the within-week forecast horizon. It suggests that the IV does not hold relevant information to forecast the volatility of the underlying currency of options for one day to four days forecast horizon. Therefore, the IV is not appropriate to estimate the currency options price for the within-week estimate horizon as reported mixed results in Table 6.2

Further, the critical findings in Table 6.1 show that the one-month and two-month maturity, begin-week day, and closing period IV holds relevant information to forecast RV for the one-week and one-month forecast horizon, respectively. It suggests that the information content embedded in one-month and two-month maturity IV is significant to forecast the volatility of the underlying currency of options one-week and one-month forecast horizon, respectively. Therefore, one-month and two-month maturity IV is appropriate to estimate the currency options price for the one-week and one-month estimate horizon, respectively, as reported in Table 6.2.

The overall results provide four critical insights. First, three-month maturity IV does not contain vital information about future volatility of the underlying currency and pricing currency options. Second, IV incorporates all information is not relevant to compute the value of currency options for less than a week estimate horizon. Third, IV of the closing period on Monday or Tuesday subsumes most of the essential information compared to other periods of a trading day and other days of a week to forecast volatility of the underlying currency and estimate the price of currency options. Fourth, the shorter (longer) maturity IV provides essential information to price currency options for the shorter (longer) estimate horizon.

6.3 Research significance

The use of foreign currency options as a hedging tool and for speculative purposes has developed significantly over the past four decades. Therefore, the accuracy of currency options pricing plays a crucial role in managing financial risk, providing a source of financial leverage for speculators as well as preventing the opportunity for abnormal arbitrage profit. If the currency options are overpriced, the hedgers and speculators experience the higher cost for buying or holding currency options. However, the options become profitable for the options seller or writer. Further, the cost of hedging and speculation is less when options are underpriced. It also makes an opportunity cost loss for the options seller. However, the arbitragers make a profit from both underpricing and overpricing of options. Therefore, an accurate prediction of the volatility of the underlying currency is very critical to prevent currency options from being under or overpriced.

The IV is widely used to estimate the volatility of FX. Most of the studies involving IV often find that the most relevant information for predicting the volatility of an underlying asset can be found in the options price. Therefore, this study is particularly interested in FX volatility prediction for pricing currency options. However, it is argued that the daily IV holds the discrete information regarding the FX movement at a specific time of the trading day, which is not sufficient for estimating options prices accurately. For example, the IV holds information based on the closing options price of trading day $t-1$ may not be relevant for computing the price of options in the opening or midday of trading day t . It means the daily IV weakens the ability to capture the critical intraday information, which is essential for accurately forecasting the FX movement for pricing options. This study, therefore, introduces intraday IV through estimating IV for the price of options with different maturity during the opening, midday, and closing period of a trading day. The intraday IV approach will add a new dimension in the literature for the pricing currency option with higher accuracy.

This study has three significant contributions to this area of research. First, this study develops the intraday IV approach based on the one-month, two-month, and three-month maturity currency options traded during the opening, midday, and closing period of a trading day, to capture the most relevant information from the continuous movement of FX market of a trading day. Second, the research findings confirm that the one-month and two-month maturity intraday IV holds vital information to forecast the volatility of the underlying currency of options for the

one-week and one-month forecast horizon, respectively. Third, this study argues that the information content embedded in the one-month and two-month maturity intraday IV is appropriate to estimate the value of currency options for the one-week and one-month estimate horizon, respectively.

6.4 Research Limitations

This section discusses some limitations of the research. The study has employed the average of bid-ask quotations for options price rather than using trading data due to the unavailability of trading prices at the intraday level. According to Hentschel (2003), errors in options price leads to reasonable errors in IV measure, which is especially true for options far from the money. Depending on the inventory of the dealers, the 'true price' (TP) is closer to the bid price or ask price at any specific point of time. Over time, the TP is expected to be the centre of the bid-ask spread (Ho & Stoll, 1981). However, the TP does not always have to lie between the bid and ask quotes (Vijh, 1990). This study tried to eliminate the effects of the bid-ask spread for the IV estimation by using ATM options price; however, the limitation still exists.

The sample data obtained for this research from the exchange-traded market is not as big as the OTC market. BIS (2019) reported that the currency options are traded not only in the exchanges, but a considerable volume of currency options also traded in the interbank market. Currently, the interest of the currency options traders has shifted from exchanges to OTC trading due to the customisation benefit of OTC currency options over options traded in exchanges. Moreover, the study limits the data sample in the five currency options that represent the developed markets. Consequently, the research findings may not be appropriate to apply for the other FX markets that experience different characteristics such as currency markets of emerging countries.

The sample data period of this study restricts the range from 1 January 2010 to 31 December 2017 due to the large volume of high-frequency data that needs to be collected. Therefore, our research captures particular economic circumstances in the context of the post-GFC crisis period. Thus, the research results may be not suitable to apply for different economic circumstances such as for the pre and during crisis period. However, the information content of the IV during a crisis period is also peculiarly relevant (Bates, 2012; Hilal et al., 2011) as it provides incremental and valuable information to hedge financial risk and to bring us a better understanding of market sentiment and behaviour. Therefore, further research need to be implemented in the future to provide a more comprehensive picture about IV performance in forecasting volatility and pricing currency options price.

6.5 Recommendations for future research

Given the limitation of this research, this study provides some recommendations for future research. An accurate and straightforward estimation framework for calculating volatility and currency options price plays a crucial role in improving volatility forecasting and options price estimating performance. As mentioned earlier, the application of average bid-ask quotations causes errors in measuring volatility, which subsequently leads to errors in pricing currency options. Therefore, it requires more attention to construct a feasible estimator of IV that minimise the noise and bias of IV estimate. It creates room for new lines of future research.

Another avenue for potential further research concerns extending this research to the emerging currency options. As each type of FX market contains peculiar characteristics, the investigations of intraday IV in developing markets is necessary to provide a fully comprehensive view for its performance in forecasting the volatility of the underlying currency and estimating the value of currency options.

Given that the dataset of this study captures the time frame of the post-crisis market, another direction of the future research is to following up study that includes intraday data from a variety of periods of different economic circumstances, such as pre-GFC (for the period before 2008), and the GFC period of 2008/2009. The objective of these future research is to examine how the intraday IV model performs in different market conditions.

Notes: GBP, IR_GBP, IR_USD, IV_GBPC, IV_GBPP, IV_GBP, GBPC_MOD, GBPP_MOD, GBPC_MKT, and GBPP_MKT represents British Pound, interest rate of GBP, interest rate of US dollar, implied volatility of GBP call options price, implied volatility of GBP put options price, implied volatility of GBP options [(IV_GBPC + IV_GBPP)/2], GBP call options model price, GBP put options model price, GBP call options market price, and GBP put options market price, respectively. The one-week estimate horizon indicates that the IV_GBP is calculated one-week before the date of estimating GBPC_MOD and GBPP_MOD.
