Abstract

We investigate a dynamic oligopoly game with price adjustments. We show that the subgame perfect equilibria are characterised by larger output and lower price levels than the open-loop solution. The individual (and industry) output at the closed-loop equilibrium is larger than its counterpart at the feedback equilibrium. Therefore, firms prefer the open-loop equilibrium to the feedback equilibrium, and the latter to the closed-loop equilibrium. The opposite applies to consumers.

JEL Classification: D43, D92, L13

Keywords: differential games, loop decision rules, subgame perfection

1 Introduction

The aim of this note consists in assessing comparatively the properties of open-loop, feedback and closed-loop memoryless equilibria in a dynamic oligopoly model with price dynamics first introduced by Simaan and Takayama (1978) and then extended by Fershtman and Kamien (1987).

Broadly speaking, the main difference between the open-loop equilibrium on one side and the feedback and closed-loop equilibria on the other, is that the former does not take into account strategic interaction between players through the evolution of state variables over time and the associated adjustment in controls. Under the open-loop rule, players choose their respective plans at the initial date and commit to them forever. Therefore, in general, open-loop equilibria are not subgame perfect, in that they are only weakly time consistent because players make their action 'by the clock' only.¹

A further distinction can be made between the closed-loop equilibrium and the feedback equilibrium, which are both strongly time consistent and therefore subgame perfect because, at any date t , players decide 'by the stock' of all state variables. However, while the closed-loop memoryless equilibrium takes into account the initial and current levels of all state variables,²

¹For an exhaustive discussion of this issue, see ch. 6 in Başar and Olsder (1982, 1995²). However, there are classes of games where open-loop equilibria are subgame perfect. See Clemhout and Wan (1974); Reinganum (1982); Mehlmann and Willing (1983); Dockner, Feichtinger and Jørgensen (1985); Fershtman (1987). For an overview, see Mehlmann (1988); Fershtman, Kamien and Muller (1992).

²The information set associated with the closed-loop decision rule can take several forms. One consists in the level of the state variable(s) at the initial and current dates. This is usually defined as the closed-loop memoryless decision rule. Another consists in the whole path of state variable(s) from the initial date to the present time. This is defined as closed-loop perfect state information rule.

the feedback equilibrium accounts for the accumulated stock of each state variable at the current date. If one player decide according to the feedback rule, then it is optimal for the others to do so as well. Hence, the feedback equilibrium is a closed-loop equilibrium, while the opposite is not true in general.³

We extend the analysis of Fershtman and Kamien (1987) to investigate the open-loop, closed-loop memoryless and feedback equilibria of an industry with more than two players. Then, we characterise the closed-loop equilibrium for this market, to show the following results: (i) both subgame perfect equilibria involve a larger production and a lower price as compared to the open-loop solution; (ii) the steady state price and output levels are, respectively, higher and lower in the closed-loop equilibrium than in the feedback equilibrium. Property (i) can be reformulated by saying that, if firms are unable to initially commit to a given output plan for the whole time horizon, then subgame perfection entails overproduction (for analogous results see Spence, 1979; and Reynolds, 1987). Property (ii) suggests that the feedback rule allows firms to reduce overproduction as compared to the closed-loop rule, precisely because according to the feedback rule they look exclusively at the current level of the state variable.

The remainder of the paper is organised as follows. The model is laid out in section 2. Sections 3 and 4, which illustrate the open-loop and the feedback equilibria, are simply the extension of Fershtman and Kamien's analysis to the oligopoly case. The closed-loop equilibrium is analysed in section 5. A comparative assessment of steady states is given in section 6. Section 7 concludes the paper.

³For an exhaustive exposition of the difference among these equilibrium solutions, see Başar and Olsder (1982, pp. 318-327, and chapter 6, in particular Proposition 6.1).

2 The setup

Probably the simplest way to think about the dynamics of market interaction consists in assuming that prices evolve over time according to some acceptable rules. That is, it consists in taking price as the state variable. This is the problem analysed in Simaan and Takayama (1978) and Fershtman and Kamien (1987).⁴ Here, we present a generalisation of Fershtman and Kamien's setup to the case of N firms.⁵

Consider an oligopoly where, at any $t \in [0; 1]$; N firms produce quantities $q_i(t)$; $i \in \{1; 2; \dots; N\}$; of the same homogeneous good at a total cost $C_i(t) = cq_i(t) + \frac{1}{2}[q_i(t)]^2$; $c > 0$:

In each period, market demand determines the price level $p(t) = A - \sum_{i=1}^N q_i(t)$: In general, however, $p(t)$ will differ from the current price level $p(t)$ since there is price stickness, and price moves according to the following equation:

$$\frac{dp(t)}{dt} - \dot{p}(t) = s [p(t) - p(t)] \quad (1)$$

Notice that the dynamics described by (1) establishes that price adjusts proportionately to the difference between the price level given by the inverse demand function and the current price level, the speed of adjustment being determined by the constant s ; with $0 < s < 1$. This amounts to saying that the price mechanism is sticky, that is, firms face menu costs in adjusting

⁴See also Mehlmann (1988, ch. 5) for an exhaustive exposition of both contributions, and Fershtman and Kamien (1990), and Tsutsui and Mino (1990) for further results on the same model, in the case of a finite horizon.

⁵An interesting application of this model to the analysis of advertising strategies is in Piga (2000). Trade policy issues are investigated by Dockner and Haugh (1990, 1991).

their price to the demand conditions deriving from consumers' preferences: they may not (and, in general, they will not) choose outputs so that the price reaches immediately $p(t)$:

The instantaneous profit function of firm i is:

$$\pi_i(t) = q_i(t) \left[p(t) - c_i - \frac{1}{2}q_i(t) \right] \quad (2)$$

Hence, the problem of firm i is:

$$\max_{q_i(t)} J_i = \int_0^1 e^{-\rho t} q_i(t) \left[p(t) - c_i - \frac{1}{2}q_i(t) \right] dt \quad (3)$$

subject to (1) and to the conditions $p(0) = p_0$; and $p(t) \geq 0$ for all $t \in [0; 1]$:

We solve the problem by considering -in turn- the open-loop solution, the feedback solution and the closed-loop memoryless solution.

3 The open-loop solution

Here we look for the open-loop Nash equilibrium, i.e., we examine a situation where firms commit to a production plan at $t = 0$ and stick to that plan forever.

The Hamiltonian function is:

$$H_i(t) = e^{-\rho t} \left[q_i(t) \left[p(t) - c_i - \frac{1}{2}q_i(t) \right] + \lambda_i(t) \left[A_i q_i(t) - p(t) \right] \right] \quad (4)$$

where $\lambda_i(t) = \mu_i(t)e^{-\rho t}$; and $\mu_i(t)$ is the co-state variable associated to $p(t)$: The supplementary variable $\lambda_i(t)$ is introduced to ease calculations as well as the remainder of the exposition. In the remainder of the paper, superscript OL indicates the open-loop equilibrium level of a variable. The outcome of the open-loop game is summarised by:

Proposition 1 At the open-loop Nash equilibrium, the steady state levels of the price and the individual output are:

$$\begin{aligned} p^{OL} &= A - Nq^{OL}; \\ q^{OL} &= \frac{(A - c)(s + \frac{1}{2})}{(s + \frac{1}{2})(1 + N) + s}; \end{aligned}$$

The pair (p^{OL}, q^{OL}) is a saddle point.

Proof. Consider the first order condition (FOC) w.r.t. $q_i(t)$; calculated using (4):

$$\frac{\partial H_i(t)}{\partial q_i(t)} = p(t) - c - q_i(t) - s_i(t)s = 0; \quad (5)$$

This yields the optimal open-loop output for firm i ; as follows:⁶

$$q_i(t) = \begin{cases} p(t) - c - s_i(t)s & \text{if } p(t) > c + s_i(t)s \\ 0 & \text{otherwise.} \end{cases} \quad (6)$$

The remaining conditions for optimum are:

$$i \frac{\partial H_i(t)}{\partial p(t)} = i q_i(t) + s_i(t)s = \frac{\partial \pi_i(t)}{\partial p(t)} \quad \frac{\partial s_i(t)}{\partial t} = s_i(t)(s + \frac{1}{2}) - q_i(t); \quad (7)$$

$$\lim_{t \rightarrow \infty} \pi_i(t) = 0; \quad (8)$$

Differentiating (6) and using (7), we obtain:

$$\frac{dq_i(t)}{dt} - \dot{q}_i(t) = \frac{dp(t)}{dt} - s[(\frac{1}{2} + s)s_i(t) - q_i(t)]; \quad (9)$$

Now, substitute into (9) (i) $\frac{dp(t)}{dt} = s[A - p(t)]$; with $p(t) = A - Nq(t)$; where a symmetry assumption is introduced for individual firm's output; and (ii) $s_i(t) = p(t) - c - q_i(t)$ from (6). This yields:

$$\frac{dq(t)}{dt} = sA + (s + \frac{1}{2})c - (2s + \frac{1}{2})p(t) + [s(1 - N) + s + \frac{1}{2}]q(t) \quad (10)$$

⁶In the remainder, we consider the positive solution. Obviously, the derivation of the steady state entails non-negativity constraints on price and quantity, that we assume to be satisfied.

Note that $dq(t)/dt = 0$ is a linear relationship between $p(t)$ and $q(t)$: This, together with $dp(t)/dt = 0$; also a linear function, fully characterise the steady state of the system. The dynamic system can be immediately rewritten in matrix form as follows:

$$\begin{pmatrix} \dot{p} \\ \dot{q} \end{pmatrix} = \begin{pmatrix} A_i - s & -N \\ s(N - 1) & sA + (s + \frac{1}{2})c \end{pmatrix} \begin{pmatrix} p \\ q \end{pmatrix} \quad (11)$$

As the determinant of the above 2×2 matrix is negative, the equilibrium point is a saddle, with

$$q^{OL} = \frac{(A_i - c)(s + \frac{1}{2})}{(s + \frac{1}{2})(1 + N) + s} ; p^{OL} = A_i - Nq^{OL} \quad (12)$$

This concludes the proof. ■

As in the duopoly case described by Fershtman and Kamien (1987 pp. 1159-61), also here the static Cournot-Nash equilibrium price and output $p^{CN}; q^{CN}$ obtain from (12), in the limit, when $\frac{1}{2} \rightarrow 0$ or $s \rightarrow 1$: For all positive levels of the discount rate and for any ...nite speed of adjustment, the static Cournot price (output) is higher (lower) than the open-loop equilibrium price (output).

4 The feedback solution

In this section, we extend the analysis of the feedback solution investigated by Fershtman and Kamien (1987) to the case of N firms. Using Bellman's value function approach, the feedback solution must satisfy the following set of Hamilton-Bellman-Jacobi equations (see Starr and Ho, 1989):

$$\frac{1}{2} V_i(p(t)) = \max_{q_i(t)} \left[q_i(t) \left(p(t) - c_i - \frac{1}{2} q_i(t) \right) + \frac{\partial V_i(p(t))}{\partial p(t)} s \left(A_i - \sum_{i=1}^N q_i(t) - p(t) \right) \right] \quad (13)$$

where $V_i(p(t))$ is the value function for firm i : Hereinafter, the indication of time will be dropped to ease the exposition. Given the linear-quadratic form of the maximand, we follow Fershtman and Kamien (1987), and propose the quadratic value function:

$$V_i(p) = \frac{k_i p^2}{2} + h_i p + g_i \quad (14)$$

so that

$$\frac{\partial V_i(p)}{\partial p} = k_i p + h_i \quad (15)$$

Henceforth, the superscript F stands for feedback. The outcome of the game is summarised by:

Proposition 2 At the feedback Nash equilibrium, the steady state levels of the price and the individual output are:

$$p^F = \frac{A + N \sum_i c_i \bar{h}_i}{N \sum_i (1 + \bar{k}_i s) + 1};$$

$$q_i^F = \begin{cases} p^F - 1 + \bar{s} \bar{k}_i + \bar{h}_i c_i & \text{if } p^F > \frac{c_i \bar{h}_i}{1 + \bar{s} \bar{k}_i} \\ 0 & \text{otherwise} \end{cases};$$

where

$$\bar{h}_i = \frac{c_i s (a_i - N c) \bar{k}_i}{\frac{1}{2} + s \bar{k}_i + 2N \bar{k}_i s + N + 1};$$

$$\bar{k}_i = \frac{c_i \left(\frac{1}{2} + 2s(N+1) \right)}{2(2N + 1)s^2 + \frac{1}{2} + 4s \left(\frac{1}{2} + N \frac{1}{2} + 2s + sN^2 \right)};$$

Proof. Taking the FOC w.r.t. q_i ; we obtain:

$$q_i^F = p_i - c_i - s \frac{\partial V_i(p)}{\partial p} = p_i - c_i - s(k_i p + h_i); \quad (16)$$

where we invoke the symmetry conditions $g_i = g$; $k_i = k$ and $h_i = h$; so that $q_i = q$ for all i : On the basis of (16) and (1), we find:

$$p^F = \frac{A + N(c_i - hs)}{N(1 - ks) + 1}; \quad (17)$$

where h and k can be calculated by the following procedure. We can rewrite (13) as:

$$\frac{1}{4}V(p)_i \max \left(\frac{1}{4} + \frac{\partial V(p)}{\partial p} s \frac{dp}{dt} \right) = 0; \quad (18)$$

that is:

$$\bar{p}_1 p^2 + \bar{p}_2 p + \bar{p}_3 = 0; \quad (19)$$

where

$$\bar{p}_1 = \frac{k[\frac{1}{2} + s(2 + 2N + ks_i - 2ksN)]_i - 1}{2}; \quad (20)$$

$$\bar{p}_2 = c_i - h(\frac{1}{2} + s + sN)_i - ks(A + Nc + hs_i - 2hsN); \quad (21)$$

$$\bar{p}_3 = \frac{2g\frac{1}{2}_i - c^2 + hs(2A + 2Nc + hs_i - 2hsN)}{2}; \quad (22)$$

Expression (19) is satisfied if expressions (20), (21) and (22), i.e., coefficients \bar{p}_1 ; \bar{p}_2 and \bar{p}_3 are simultaneously zero. This makes up a system of three equations in three unknowns, g ; h ; k ; with the following solutions:

$$g = \frac{c^2_i - hs(2A + 2Nc + hs_i - 2hsN)}{2\frac{1}{2}}; \quad (23)$$

$$h = \frac{c_i - s(a_i - Nc)\bar{k}}{\frac{1}{2} + s - \bar{k}s_i - 2N\bar{k}s + N + 1}; \quad (24)$$

$$k = \frac{\frac{1}{2} + 2s(N + 1) \pm \sqrt{\frac{1}{2}^2 + 4s(\frac{1}{2} + N\frac{1}{2} + 2s + sN^2)}}{2(2N_i - 1)s^2}; \quad (25)$$

We choose the smaller solution for k in (25), which yields - when $N = 2$ - the same expression as in Fershtman and Kamien (1987, Theorem 2, p. 1157).

This establishes that

$$\bar{k} = \frac{\frac{1}{2} + 2s(N + 1) - \sqrt{\frac{1}{2}^2 + 4s(\frac{1}{2} + N\frac{1}{2} + 2s + sN^2)}}{2(2N_i - 1)s^2}; \quad (26)$$

This concludes the proof. ■

5 The closed-loop solution

The closed-loop memoryless solution remains to investigate. We use superscript CL to denote the closed-loop equilibrium levels of the relevant variables. The Hamiltonian of firm i is given by (4), and the outcome is summarised by the following:

Proposition 3 At the closed-loop Nash equilibrium, the steady state levels of the price and the individual output are:

$$\begin{aligned} p^{CL} &= A_i - Nq^{CL}; \\ q^{CL} &= \frac{(A_i - c)(\frac{1}{2} + sN)}{(N + 1)\frac{1}{2} + (N^2 + N + 1)s}. \end{aligned}$$

The pair (p^{CL}, q^{CL}) is a saddle point.

Proof. The first order condition w.r.t. q_i calculated using (4), obviously coincide with condition (5) calculated in the open-loop case:

$$\frac{\partial H_i}{\partial q_i} = p_i - c_i - q_i - s_i s = 0: \quad (27)$$

This yields the closed-loop output for firm i ; as follows (again, in the remainder we shall consider only the positive solution):

$$q_i^{CL} = \begin{cases} p_i - c_i - s_i s & \text{if } p > c + s_i s \\ 0 & \text{otherwise.} \end{cases} \quad (28)$$

The remaining conditions for optimum are:

$$i \frac{\partial H_i}{\partial p} - \sum_{j \in i} \frac{\partial H_i}{\partial q_j} \frac{\partial q_j^{CL}}{\partial p} = \frac{\partial s_i}{\partial t} + \frac{1}{2} s_i \quad (29)$$

Now consider that

$$\frac{\partial H_i}{\partial q_j} = i_{-j} s; \quad \frac{\partial q_j^{CL}}{\partial p} = 1; \quad (30)$$

Therefore:

$$\sum_{j \in i} \frac{\partial H_i}{\partial q_j} \frac{\partial q_j^{CL}}{\partial p} = i \sum_{j \in i} s \quad (31)$$

is the additional term in the co-state equation, characterising the strategic interaction among firms, which is not considered by definition in the open-loop solution (see, e.g., Driskill and McAfee, 1989). Equation (29) may be rewritten as: $\dot{q}_i + s_i s + \sum_{j \in i} s_j s = \frac{\partial s_i}{\partial t} + \frac{1}{2} s_i$; and, invoking symmetry,

one obtains:

$$\frac{\partial s}{\partial t} = i q + s (\frac{1}{2} + N s) \quad (32)$$

Then we have the transversality condition:

$$\lim_{t \rightarrow \infty} e^{-\rho t} p = 0 \quad (33)$$

Differentiating (28) w.r.t. time and using (32), we obtain:

$$\frac{dq_i}{dt} = \frac{dp}{dt} i s [(\frac{1}{2} + w) s_i i q_i] \quad (34)$$

Now, substitute into (34) the expressions (i) $dp=dt = s f p_i p g$; with $p(t) = A_i N q$; where a symmetry assumption is introduced for individual firm's output; and (ii) $s_s = p_i c_i q$ which obtains from (27). This yields:

$$\frac{dq}{dt} = \frac{1}{2} (c_i p + q) + s [A_i p + q_i N (p_i c)] \quad (35)$$

As in the open-loop case, $dq=dt = 0$ is a linear relationship between p and q : This, together with $dp=dt = 0$; which is also a linear function, yields

$$p^{CL} = A_i \frac{N (A_i c) (\frac{1}{2} + sN)}{(N + 1) \frac{1}{2} + (N^2 + N + 1) s}; \quad (36)$$

$$q^{CL} = \frac{(A_i c) (\frac{1}{2} + sN)}{(N + 1) \frac{1}{2} + (N^2 + N + 1) s};$$

as the unique steady state of the system.⁷ The dynamic system can be immediately rewritten in matrix form to verify that the pair (p^{CL}, q^{CL}) is a saddle point. The proof of this is omitted for the sake of brevity. ■

6 Comparative assessment of steady states

Now we can compare the steady state levels of price and individual output in the three cases analysed above, as well as in the static case. The following result emerges.

Proposition 4 For all $s \in [0; 1]$ and all $N \in [1; \infty)$;

$$\begin{aligned} q^{CL} &> q^F > q^{OL} > q^{CN} ; \\ p^{CN} &> p^{OL} > p^F > p^{CL} ; \end{aligned}$$

The proof is straightforward. In words, confining our attention to the equilibria of the dynamic setting, all subgame perfect equilibria entails a higher (individual and industry) output and a lower market price than the open-loop equilibrium (which is not subgame perfect). Therefore, Proposition 4 produces a relevant Corollary:

Corollary 1 From the firms' viewpoint, the open-loop equilibrium is preferred to both the feedback equilibrium and the closed-loop memoryless equilibrium. On the contrary, the closed-loop memoryless equilibrium is socially preferred to the feedback and open-loop equilibria.

Fershtman and Kamien (1987, pp. 1159-61) also investigate the properties of the limit games, where the speed of adjustment s tends to infinity or

⁷Of course by "unique" we mean the only steady state with positive price and outputs.

$\frac{1}{2}$ becomes nil. They establish that, in such cases, the open-loop equilibrium coincides with the Nash equilibrium of the static game. However, considering an infinitely high speed of price adjustment seems more a mathematical curiosum than a theoretically relevant case, in that whenever $s > 1$; the instantaneous change in price is larger than the error $p(t) - p^*(t)$: If we confine to $s \in [0; 1]$; we obtain the following Corollary to Proposition 1:

Corollary 2 When $s = 1$;

$$q^{OL} = \frac{(A - c)(1 + \frac{1}{2})}{(N + 1)(1 + \frac{1}{2}) + 1}$$

which is larger than the static Cournot-Nash output

$$q^{CN} = \frac{A - c}{N + 2}$$

for all $N \geq 1$ and all $\frac{1}{2} > 0$:

In the limit, as $\frac{1}{2} \rightarrow 0$; $q^{OL} \rightarrow q^{CN}$ for all admissible N and s :

Finally, one can check what happens to the steady state levels of output as N tends to infinity, to verify the following Corollary to Proposition 4:

Corollary 3 As the number of firms becomes infinitely large, optimal individual output tends to zero independently of the solution concept.

Therefore, as the market becomes perfectly competitive, open-loop, closed-loop and feedback solutions coincide with the static Cournot-Nash solution, which is itself reproducing the perfectly competitive outcome.

7 Concluding remarks

We have investigated the properties of a dynamic oligopoly game with sticky prices. The foregoing analysis shows that subgame perfection always entails larger output and lower price levels in steady state, as compared to

the weakly time consistent open-loop solution. In particular, the individual and industry output associated to the closed-loop equilibrium is larger than its counterpart at the feedback equilibrium. Two further (and related) remarks are in order. First, the foregoing analysis highlights that the larger the relevant information set, the larger the overproduction compared to the (commitment) open-loop equilibrium. The second is that among the sub-game perfect solution concepts, the feedback rule appears to be able to minimise overproduction. Accordingly, while firms would prefer the open-loop equilibrium to the feedback equilibrium, and the latter to the closed-loop equilibrium, the opposite holds from the social standpoint.
