

Deformation of Pipelines Induced by the Construction of Underlying Twin-Tunnel

Jinlong ZHU*, Dayong ZHU

Abstract: The soil displacement load induced by the metro tunneling is applied to the adjacent pipelines, which leads to the deformation of the pipelines, and affects the safe use of the pipeline. According to the displacement of the soil caused by the excavation of the twin-tunnel, considering the shear deformation of the soil and the angle between the tunnel and the pipeline, the analysis method of the Pasternak foundation beam for the longitudinal displacement of the pipeline caused by tunneling was established. The calculation result was relatively close to that of the numerical simulation based on displacement controlled method (DCM) and the field measured data. The influences of the angle, the distance between tunnel axes, the soil volume loss rate and the relative bending stiffness on the pipeline deformation were analyzed. Finally, the influence of the shearing stiffness of the pipeline was researched based on the Timoshenko beam model.

Keywords: Pasternak foundation; pipeline; shearing stiffness; tunnel

1 INTRODUCTION

During the construction of urban subway, the tunnels crossing pipeline is normally inevitable. However, the displacement load of the upper soil caused by tunneling will be applied on the pipelines, resulting in deformation of the pipelines, which will seriously affect their normal and safe service. Attewell and other researchers [1] first analyzed the influence of tunnel excavation on the longitudinal deformation of the upper pipeline by using the two-stage method based on the Winkler elastic foundation beam model. This method is one of the commonly used methods to describe the pipe-soil interaction [2, 3]. However, the Winkler foundation model does not consider the continuity of foundation deformation and ignores the shearing deformation of soil. Some scholars adopted Pasternak foundation model in the two-stage method and obtained relatively accurate results [4, 5]. A number of researches are confined to single line tunnel; actually the analysis of the influence of twin-tunnel construction on the deformation of the pipeline is of greater importance. Moreover, the researchers are generally concentrated on the condition of pipeline perpendicular to the tunnel. Shi and other researchers [6], based on the centrifuge model test, indicated that the angle size has a great influence on the pipeline settlement and strain caused by tunneling. Moreover, the influence of the pipeline shearing stiffness on the deformation is also one of the factors needed to be considered. In addition to the two-stage equivalent foundation beam method, some scholars have made helpful explorations on this problem based on the numerical simulation by the displacement control method [7, 8]. The displacement control method can directly apply displacement around the tunnel to reflect the stress release caused by excavation. It can simulate the soil loss rate of the stratum with high accuracy.

This paper considered the shearing stiffness of the foundation and the angle of the tunnel and pipeline, and established Pasternak foundation beam analysis method targeting at the pipeline longitudinal displacement caused by tunnel excavation, and compared the calculation results with DCM numerical simulation and field measurement based on a case, and analysed the influence of the angle, the tunnel axes distance, soil loss rate, relative bending stiffness on the pipeline deformation, and finally, the

influence of pipeline shearing stiffness based on Timoshenko beam model was taken into account.

2 SOIL DISPLACEMENT CAUSED BY TUNNEL EXCAVATION

The settlement of the soil below the ground caused by tunneling still conforms to the Gaussian distribution law [9], and the settlement trough width is related to the tunnel depth and the ground settlement trough width coefficient [10]. Combined with Liu's study about the twin-tunnel based on the superposition principle [11], the formula of the formation settlement induced by the twin-tunnel excavation is:

$$S = \frac{1.25R^2V_1}{K(z_1 - z_2)} \left\{ \exp \left[-\frac{\left(x - \frac{L}{2}\right)^2}{2K^2(z_1 - z_2)^2} \right] + \exp \left[-\frac{\left(x + \frac{L}{2}\right)^2}{2K^2(z_1 - z_2)^2} \right] \right\} \quad (1)$$

$$K = \frac{1 - \eta \left(\frac{z_2}{z_1} \right)}{1 - \frac{z_2}{z_1}} K_0 \quad (2)$$

where R is the tunnel radius (m); V_1 is the soil volume loss rates caused by single tunnel excavation; z_1 is the tunnel depth (m); S is the settlement of the soil with z_2 in depth (m), L is the distance of the twin-tunnel axes (m); and K_0 is the settlement trough width coefficient of the ground. K is the settlement trough width coefficient of the soil with z_2 in depth, and η is the parameter about the soil, which is 0.65 for clay soil and 0.50 for sandy soil.

3 PIPELINE DEFORMATION

The two-stage foundation beam analysis method is used to study the settlement of the upper pipeline caused by tunnel excavation. It is assumed that the pipeline is always in contact with the soil. The pipeline is regarded as the Pasternak foundation beam, and the generalized displacement load caused by tunnel excavation is applied to the elastic foundation beam, and a balanced differential equation for the longitudinal deformation of the pipeline is

established. The tunnel crosses the pipeline vertically or obliquely, as shown in Fig. 1, when the angle between the two is θ , the displacement of the soil at the location of the pipeline caused by the twin-tunnel excavation is:

$$f(x) = \frac{1.25R^2V_1}{K(z_1 - z_2)} \left\{ \exp \left[-\frac{\left(x \sin \theta - \frac{L}{2}\right)^2}{2K^2(z_1 - z_2)^2} \right] + \exp \left[-\frac{\left(x \sin \theta + \frac{L}{2}\right)^2}{2K^2(z_1 - z_2)^2} \right] \right\} \quad (3)$$

Figure 1 Calculation sketch

The two-parameter Pasternak foundation model contains the spring layer and the shear layer reflecting the soil properties, and the relationship between the ground reaction force and the soil layer displacement is:

$$p(x) = -G \frac{d^2 f(x)}{dx^2} + kf(x) \quad (4)$$

where, $p(x)$ is the ground reaction force, G is the foundation shear modulus (N/m), and k is the foundation bed coefficient (Pa/m). Based on the simplified elastic space method [12, 13], for a foundation with an elastic modulus of E (Pa), the Poisson's ratio of ν , and a thickness of h , there is:

$$G = \frac{EH}{6(1+\nu)} \quad (5)$$

$$k = \frac{E}{H} \quad (6)$$

According to Xu Ling's research, the additional stress at the base where 6 times of pipeline diameter below the pipeline decreases into a negligible extent, so the H value is taken as 6 times the pipeline diameter [14].

The pipeline is set as an Euler-Bernoulli beam, and the equilibrium differential equation of the pipeline with z_2 in depth is:

$$\frac{d^4 w}{dx^4} - \frac{2rG}{D} \frac{d^2 w}{dx^2} + \frac{2rk}{D} w = \frac{2rk}{D} f(x) - \frac{2rG}{D} f(x)'' \quad (7)$$

where w is the settlement of the pipeline, r is the pipeline radius, and D is the bending stiffness of the pipeline.

Tunnel excavation does not affect the pipeline in the distance, and there is:

$$w(x)|_{x \rightarrow \pm\infty} = 0 \quad (8)$$

$$w(x)'|_{x \rightarrow \pm\infty} = 0 \quad (9)$$

Combining Eq. (3) and Eq. (7) to Eq. (9), the numerical fitting curve of the pipeline settlement $w(x)$ can be calculated by numerical analysis software.

4 ENGINEERING APPLICATION

The total length of the tunnel of Zhenpu Road ~ Zhijiang Ocean Park Station of Hangzhou Metro Line 6 is about 2745 m. It is constructed by two earth pressure balance shield machines. The left and right tunnels have the same buried depth. The tunnel diameter is 3.1 m. The twin-tunnel crosses a rigid concrete rainwater pipeline near the Ocean Park Station. The tunnels are 15 m in depth, and the distance of tunnel axes is 12 m, and the pipeline is 3.2 m in depth, 1.1 m in diameter and $1.7 \times 10^9 \text{ N}\cdot\text{m}^2/\text{m}$ in bending stiffness, and the angle between the tunnel and the pipeline is 75° . The soil layer is mainly silty clay, mucky silty clay containing silt, and according to the thickness-weighted average, the elastic modulus of the soil is $2.4 \times 10^7 \text{ Pa}$ and the Poisson's ratio is 0.36.

The settlement monitoring data of the ground was fitted with the Peck formula as shown in Fig. 2, and the obtained formation loss rate of the ground was 0.75%, and the settlement trough width coefficient was 0.68.

Figure 2 Peck formula fitting of the ground settlement

Figure 3 Three-dimensional model

The case was calculated respectively by the above foundation beam method, 3D finite difference program FLAC3D simulation, and field measurement and the obtained results were compared and verified. In the

numerical simulation, in order to keep consistent with the foundation beam method, the soil was set as linear elastic constitutive model, and the pipeline was simulated by beam element, and the elastic modulus of the beam element was $3e^{10}$ Pa and the Poisson's ratio was 0.2. The model size was $100 \times 35 \times 60$ m, as shown in Fig. 3. The bottom of the model was fully constrained, and the side is horizontally constrained, and the top surface is free.

The numerical simulation used the displacement control method based on the soil volume loss rates (DCM) [15, 16], in which a non-uniform contraction boundary displacement condition was applied around the tunnel, as shown in Fig. 4. The horizontal and vertical displacement expressions for the tunnel boundary nodes are:

$$u_x = -\frac{g}{2}(1 + \sin\alpha) \cdot \cos\alpha \tag{10}$$

$$u_y = -\frac{g}{2}(1 + \sin\alpha) \cdot \sin\alpha \tag{11}$$

where $g = 2R(\sqrt{1+V_1} - 1)$, and g is the gap parameter (m), and u_x, u_y are the horizontal and vertical displacement of the tunnel boundary.

Figure 4 Sectional contraction displacement mode

Figure 5 Comparison of the longitudinal displacement curve of the pipeline

Fig. 5 shows the longitudinal displacement curve of the pipeline based on the two-stage foundation beam method, DCM method and field measurement (the position located directly above the middle of the twin-tunnel is the midpoint of the pipeline). It can be seen that there are some differences between the two obtained curves in the foundation beam method and the numerical simulation method, and the latter changes more gently, but the trends of the two are similar, and basically conform to the

measured results, which proves the effectiveness of the two-stage foundation beam method.

5 INFLUENCE FACTORS ANALYSIS

The settlement of the pipeline caused by tunneling is related to the relative location of the tunnel and pipeline, the design and construction of the tunnel, and the stiffness of the pipeline, such as the angle between the pipeline and the tunnel, the distance between the axes of the twin-tunnel, the soil volume loss rates, and the relative bending stiffness. Based on the previous case, the single factor impact analysis was carried out to obtain the settlement curve of the pipeline under different parameters, as shown in Fig. 6 to Fig. 9, where the relative bending stiffness of the pipeline is $\lambda = D/Ei^3r$ [2]. It can be seen from the figure that the angle between the tunnel and the pipeline has little effect on the settlement of the middle part of the pipeline, and on the whole, the settlement of the pipeline decreases with the increase of the angle. For the spacing L of the tunnel axes, as the L increases, the maximum settlement decreases, and the soil volume loss rate of the twin-tunnel excavation produces a superposition effect on the pipeline. When L is shorter than 20 m, the maximum settlement is located at the midpoint of the pipeline, and if L is longer than 20 m, the superposition effect of the two tunnels' excavation is weakened, and the maximum settlement occurs at the symmetric "double valleys" of the displacement curve. As to the soil volume loss rate, it can be seen that the pipeline settlement value is sensitive to it. Therefore, one of the keys to control the settlement of the pipeline is to control the construction quality of the tunnel and reduce the soil loss. The bending stiffness of the pipeline also has a significant effect on the settlement value of the pipeline. As the relative stiffness of the pipeline decreases, the settlement becomes smaller, and the deformation curve becomes smoother.

Figure 8 Longitudinal displacement curve of the pipeline with different soil volume loss rates

Figure 9 Longitudinal displacement curve of the pipeline with different relative bending stiffness

6 EFFECT OF SHEARING STIFFNESS ON PIPELINE DEFORMATION

As above, the pipeline is regarded as the Euler-Bernoulli beam model, in which only the bending stiffness can be considered while in the Timoshenko beam model, both the bending stiffness and the shearing stiffness of the pipeline can be taken into account. According to the

Figure 10 Influence of shearing stiffness on longitudinal displacement of different pipelines

In the deformation analysis of the three types of pipelines, other parameters of pipeline, tunnel and formation are set as above, and as calculated by Eq. (7) and Eq. (12) respectively, the effect of shearing stiffness on the longitudinal deformation of pipelines caused by the tunneling is shown in Fig. 10. It can be seen that for different types of pipelines, the shearing stiffness has little influence on the settlement curve of the pipeline, and the maximum settlement error without consideration of the shearing stiffness does not exceed 1%. Therefore, for common pipelines, in the calculation of the settlement value caused by tunnel excavation, the impact of the

equilibrium differential equation of the displacement and rotation angle, the settlement equation of the Timoshenko beam on the Pasternak foundation can be obtained.

$$\left(\frac{2rG}{C} + 1\right) \frac{d^4 w}{dx^4} - \left(\frac{2rk}{C} + \frac{2rG}{D}\right) \frac{d^2 w}{dx^2} + \frac{2rk}{D} w = \frac{2r}{D} (kf(x) - Gf''(x)) - \frac{2r}{C} (kf''(x) - Gf^{(4)}(x)) \tag{12}$$

where the shear strength of the pipeline $C = \kappa G_b A$, the shear correction coefficient $\kappa = 6(1+m^2)^2 / [7(1+m^2)^2 + 20m^2]$

(Cowper correction theory), m is the ratio of the inner and outer diameter of the pipeline), and G_b is the shear modulus of the pipeline (Pa), and A is the cross-sectional area of the pipeline (m^2).

Combining Eq. (3), Eq. (8), and Eq. (9), the numerical fitting curve of pipeline settlement can be calculated by the numerical analysis software.

Table 1 Calculation parameters of pipelines

Category	Diameter / m	Wall thickness / m	Elastic modulus / Pa	Shear modulus / Pa
Ductile iron pipe	2.6	0.03	1.5e11	7.5e10
Concrete pipe	3.0	0.2	3e10	1.2e10
Steel pipe	2.5	0.02	2.06e11	7.9e10

In order to analyze the influence of the shearing stiffness of the pipeline on the deformation, the common pipelines, such as the ductile iron pipe, the concrete pipe and the steel pipe were taken as the research subjects. Because of the obvious shearing stiffness of the deep beam, the diameter and wall thickness of each pipe was set large, as shown in Tab. 1.

shearing stiffness of pipelines can be ignored.

7 CONCLUSION

(1) According to the displacement of the soil caused by the excavation of the twin-tunnel, considering the shear deformation of the soil and the angle between the tunnel and the pipeline, the analysis method of the Pasternak foundation beam for the longitudinal displacement of the pipeline caused by tunnel excavation is established. The calculation result is relatively close to that of the numerical simulation based on displacement controlled method

(DCM) and the field measured data. This method can be used to estimate the settlement of the continuous rigid pipeline caused by the construction of the underlying twin-tunnel.

(2) The angle between the tunnel and the pipeline has little effect on the settlement in the middle of the pipeline, and on the whole, the settlement of the pipeline decreases with the increase of the angle. The maximum settlement of the pipeline decreases with the increase of the soil volume loss rate and the relative bending stiffness, and increases with the increase of the spacing of tunnel axes.

(3) For the common pipelines, when calculating the settlement value caused by tunnel excavation, the error without consideration of the shearing stiffness is not more than 1%, and the influence of the shearing stiffness can be ignored. It is reasonable to use the Euler-Bernoulli beam model.
