

GOBEX-III

Fahrtbericht/Cruise Report
FS POSEIDON
Gotland Becken
Rostock-Kiel
04.03. - 13.03. 1996

Institut für Ostseeforschung an der Universität Rostock

Sektion Marine Geologie

Abstract

Cruise GOBEX-III was the second expedition mounted by the IOW Marine Geology Group under Project GOBEX to investigate the geochemical and sedimentological environment in the Gotland Basin of the Central Baltic Sea. The cruise concentrated on improving the coverage with shallow seismic profiles (GEOCHIRP sonar), shallow sediment cores (Multicorer) and long gravity and Kasten cores of various depths in the Gotland Deep and adjacent basins. Using acoustic methods, we mapped the local accumulations of mud (Schlick) in basin-normal and along-strike profiles. The accumulations of mud and underlying lacustrine clays were sampled by shallow multi-coring and gravity coring (to 12 m, maximum of 10.5 m recovery). Cores were subsampled onboard ship for porewater, sedimentological, and magnetic analyses in shorebased laboratories. A first exploratory survey of sediments was carried out in the Gdańsk Basin by seismic soundings, surface sediment sampling, and gravity coring. Two gravity cores were taken in the Arkona Basin.

Danksagung/Acknowledgements

We thank Kapitän Bülow and his crew for the excellent working conditions and good atmosphere during the cruise. The Institute für Meereskunde Kiel is acknowledged for providing shiptime on POSEIDON. Thanks to the GPI Kiel (Prof. Stoffers, Dr. Kögler) and GEOMAR (Dr. Kassens) and their equipment, we were able to take some excellent cores.

Einführung und Ziele/Background and Objectives:

GOBEX (Gotland Basin Experiment) was initiated in 1993 as a multidisciplinary experiment to investigate the oceanographic, chemical, biological and sedimentological situation in the Gotland Basin of the Central Baltic Sea. It is a direct result of scientific conferences sponsored by ECOPS on the future of Baltic Sea research; scientific goals formulated for GOBEX thus closely reflect its primary purpose: To mount an interdisciplinary and international pilot study of processes in the deep Baltic Sea which may serve as nucleus for future cooperation among Baltic geoscientists.

The "benthic and geological processes" task force of GOBEX defined its contribution as follows: It set out to study the Gotland Basin as an end-member in the dynamic depositional environment of the Baltic Sea. The pilot study with cruise GOBEX II (F/S A. v. HUMBOLDT; August, 1994) as an initial sampling campaign aimed to clarify

pathways of materials, their modifications and post-depositional and biological processes in the final depositional sink. This included the initial identification of mass fluxes of natural and anthropogenic substances, evaluation of transport processes, biological and geochemical processes, and sampling short (<200 years) and long (>1000 years) sedimentary records to hindcast historical and geological environments.

The cores taken during that cruise proved to be very interesting in their potential to hindcast saltwater inflows by characteristic manganese carbonate beds which appear to coincide with historical ingressions of saline waters (Neumann et al., in press). Emeis et al. (submitted) found indications of considerable sediment dynamics in the surficial layer of antropogenically influenced sediments and in trace metal profiles and accumultion rates.

Based on these preliminary results and on acoustic profiles of excellent quality, we decided to enlarge the areal coverage of acoustic profiles and to concentrate them in areas of mud accumulaton and structural features in the Holocene or Pleistocene subsurface. In several areas, the different reflectors were potentially within reach of the long sediment cores (12 m) that can be taken with the F/S POSEIDON. These long cores will be used to identify seismic reflectors and to compile basinal sediment sections that reach back to the Baltic Ice Lake stage of Baltic Sea evolution. Once optimal sediment sections for each stage (emphasis is on the Littorina Stage) have been compiled, we intend to date them and analyse them for a series of paleoclimatic and paleoenvironmental indicators in the sediments. The final goal is to establish a high-resolution history of the Central Baltic Sea evolution over the last 7600 years. Additional tasks during the POEIDON cruise were to take pore water samples for shorebased analyses of the sulfur system in the sediments, and paleomagnetic samples to study the variations in the geomagnetic field.

Participants and Participating Institutions

Instrumentation and Methods

Navigation

All coordinates given are geographical coordinates obtained from GPS navigation. The geoid used is WGS 84. For seismic profiling, a separate GPS system was employed and the positions were automatically stored on the tracks and on paper printout.

Acoustic Work/ IOW (Endler)

We employed a GeoChirp Subbottom Profiler System for the acoustic surveys. The Chirp profiler (transmitted signal 2 to 8 kHz or 1.5 to 11.5 kHz, depending on operating mode) consisted of a deck unit and a tow fish. The penetration depth of the unit was up to 40 m below seafloor and typically had high resolution (0.3-0.5 m). Some examples are give in the Appendix. The shooring rate was 4 per second. Signal processing was performed with a Sonar Enhancement System and data were digitally stored on 8 mm DAT tapes in SEGY format. Navigation data were obtained from a separate GPS and stored.

Based on results of the acoustic surveys, we targeted sediment and water-column stations to areas where echograms indicated high sediment accumulation and where the acoustic stratigraphy promised recent sediment cover. This approach was very successful and yielded generally good results in sediment cores recovered.

Equipment used for Geological Work and Sediment sampling

Four different tools were used to obtain sediment samples.

The Niemistö-Lot, a short gravity corer with a plastic tube of 8 cm diameter and 50 cm length, which is used to log physical properties of surface sediments.

A multicorer, which provides up to eight sediment cores from an area of 1.5 m² to a depth of 45 cm and ideally recovers bottom water. Several of these sub-cores were sliced in 1 cm thick discs on board and either stored frozen for shorebased analyses, or centrifuged to obtain porewater samples. Other subcores were left intact for future subsampling.

A gravity corer (Schwerelot) with an inner plastic liner and a top weight of initially 1200 kg, later of 850 kg. A maximum length of 10 m sediment was recovered with this weight, which was found to be sufficient for penetrating the soft sediment of the Gotland Basin. The liners were cut into sections of 1 m length, capped, and stored for shorebased logging.

A Kastenlot of 15x15 cm diameter and variable length, weighted by 1200 to 2200 kg of lead. The longest core recovered was 970 cm. These cores were opened on board, slabs and u-channels were taken over the entire length for x-ray photography and magnetic measurements, and the cores were described after visual examination. In addition, discrete samples were taken for porewater and sediment analyses.

Cruise Narrative

R/V POSEIDON left Rostock-Warnemünde on March 4, 1996 at 12:00z and headed for the Gotland Basin. The southern Baltic Sea was covered with sea ice of considerable thickness (<30 cm) to approximately 14°E after the severe winter. Eastward of the Kadettrinne, the water was open and the sea was calm, so that all instrumentation was set up and checked. During the transit the wind increased to 6 Bft from the N and several of the scientific crew paid their dues to Poseidon. Fortunately, the weather improved considerably on the day of arrival to the area of operation. Figure 1 is a map giving all stations and survey tracks in the Gotland Basin area.

The first station was occupied at HELCOM station 271 on March 6 at 08:00z (Station 201300/Poseidon 204; station list is in Table 2). Here, a sediment trap mooring was deployed with two traps (Type....) and an Aanderra current meter, as well as with 5 temperature loggers (Fig. 2). Our program consisted of several futile and finally successful runs with water sampling bottles (4L) to depths of 150 m in order to obtain deep water to fill the cups. At 10:14 GMT (=z-1 hour), the trap was finally deployed and the ship relocated to our first sediment sampling station 201301. This station is located in an area where the Littorina mud is relatively thin and underlying layers were in reach of the corer. Fig. 3 depicts a section of acoustic profile an the position of station

201301 ($57^{\circ}20.16'N/19^{\circ}57.41'E$). After two runs with the Niemistölot, a multicorer was run which overpenetrated and was discarded. A second multicorer was successfully deployed and recovered 8 subcores. All core descriptions are given in the Appendix. Following this, we obtained a Kastenlot with 1070 cm sediment. The thick varved clay at the base (brownish-pink with light, cream-colored interlayers) was intensely fractured and disrupted by synsedimentary features.

Following the sampling program, the first of a series of GEOCHIRP-profil were run during the night. Start, turning, and end points of these profiles are given in Table 3. Conditions were excellent and the digitally recorded soundings are of very good quality.

On March 7, operations continued a 08:23 GMT at Station 201302 ($57^{\circ}N15.05'N/20^{\circ}11.95'E$) with a Kastenlot that was discarded because it was only partly filled. Figure 4 depicts the location on an acoustic profile. The station was selected to obtain an expanded interval of Littorina mud from what appears to be a contour deposit at the foot of the eastern basin slope. Here, acoustic reflectors thought to be Littorina mud were exceptionally thick. After three Niemistölote, which also overpenetrated, a Kastenlot recovered 687 cm of plastic, water-rich Littorina mud that was intensely laminated and stained with black iron monosulfide. As a last tool, we ran the Multicorer in several runs. One of these yielded sediment, but may have overpenetrated in spite of wooden support beams which were attached to the frame to prevent it from sinking into the mud. Several other attempts were unsuccessful and the operation was aborted.

We then occupied station 201303 ($57^{\circ}11.09'N/19^{\circ}55.68'E$) from 15:13 GMT and obtained a fine multicorer from this southerly position. Figure 5 shows the site on an acoustic profile. The bottom water in the cores was devoid of oxygen and gave an Eh reading of -80 mV. The sediment surface was covered with brownish, gelatinous debris and white remains of bacterial mats (?) overlying a black, grainy sediment with flocs. Until 15:50 GMT, two Niemistölote were also taken at Station 201303, and the ship resumed the seismic survey of lines 6 to 9. Again, sea conditions were very favorable and the data are of good quality.

On March 8, long gravity cores were taken at positions previously sampled by kastens and multicores. Station 201304 is at $57^{\circ}11.14'N/19^{\circ}55.69'E$ and yielded 1010 cm of core (Ice lake brownish clay at the base). Station 201305 is at $57^{\circ}15.41'N/20^{\circ}11.81'E$ and, after two futile attempts and a reduction of head weight from 1.2 to 0.85 t, yielded 900 cm of Littorina mud. Station 201306 at $57^{\circ}22.66'N/20^{\circ}17.84'E$ yielded 900 cm of sediment and ended brown clay at the base. We then relocated the ship to a small basin SW of Klints

Bank (station 201307; 57°00'N, 019°26.99'E in water 182 m deep). A gravity core brought 995 cm of sediment which was brownish clay at the base, and two Niemistö-Lote were taken. At 22:13 z the ship resumed the survey of acoustic profil 10 and then transited to the Gdansk Basin.

After a transit of 100 nm, the GEOCHIRP was deployed at 05:55 GMT on March 9 for an initial survey across the intended sediment sampling station #201308 (54°49.9'N/019°18.4'E, 117 m water depth). The soundings show a gradually thickening wedge of mud overlying acoustically banded layers presumed to be lacustrine clays. Having finished the survey, we took a gravity corer at 11:09 GMT. The corer overpenetrated about 2 m and yielded 10.7 m of sediment with grey clay at the base. In addition, we sampled a multicorer and two Niemistölote. The multicorer provided 45 cm of sediment with bottom water. The Eh of the bottom water was +180 mV and the silty to slightly sandy sediment was covered with a dense, brownish bacterial mat of *Beggiatoa*. After coring, four additional seismic profiles were collected in roughly N-S and E-W directions. Some shallow gas caused acoustic turbidity at several depressions, but the subsurface was very uniforma and lacked structure.

On March 10, the program was to collect a 12 m Kastencore at the location of station #201309. An initial attempt with a head weight of 850 kg of lead yielded only 3 m of seidment and it was decided to try again with a full set of weights (2.2 t). Unfortunately, this was excessive and the second attempt resulted in two severely damaged kastens. Operations were aborted and the ship set out to transit to the coring locations in the Arkona Basin at 09:00 GMT.

The next day (March 11) saw increased winds from the E (6 Bft) and cold temperatures with ice on deck. At 08:00z we decided to try taking the Schwerelote at the two positions in the Arkona Basin and we reduced the head weight of the corer to approximately 1.6 t. At the first position (station # 201310) we recovered 985 cm of sediment with the 11 m long corer; t the base we found brown "Rosa" clay of the ice lake stage. At the second position (station # 201311) we cored only 785 cm, again bottoming out in brown clay. Upon pulling the corer out of the seafloor, the winch registered a pull-out weight of >5t, which may indicate a stiff, harder layer which was not penetrated. At 09:50z operations finished and the ship headed towards Warnemünde. We arrived in Rostock on 11. 3. 96 at 18:00z. The ship was unloaded on 12.3. and departed to Kiel at 16:00 z. The expedition ended in Kiel on 13.3. after the transit and unloading of all equipment.

Zeit: 1015 Breite: 57° 18,0' N Länge: 020° 14,0' E (Ankerstein)

Die Verankerung kann mit der Position:

Breite: 57° 17,95' N Länge: 020° 14,1' E

als richtig angenommen werden.

Magnetische Mißweisung: 4° E Grad

Akustischer Anruf nach dem Auslegen

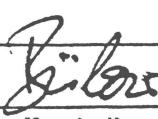

nein

o.k.

Zeit: 1022

Bemerkungen:

DIE VERANKERUNG WURDE ÜBER DAS HECK AUSGELEGT.

Kapitän

Position: 54°49.9'N/ 019°18.9'E

117 m Wassertiefe

Multicorerbeschreibung

SCHLICK, leicht sandig,
grauschwarz bis schwarz,
mit Monosulfid imprägniert.
Unten undeutlich gebändert und
ansonsten homogen.
0-0.2 cm: Bakterienmatte (*Beggiatoa*),
bräunlich und filzig mit Detritusaufgabe.
0.2-0.7 cm: Schwarze, flockige Schicht
Sehr wasserreich bis 6 cm.
Sulfidgeruch im gesamten Tiefenintervall
