# Bias of oceanic N<sub>2</sub>O emission estimates by multi-day near-surface stratification in the Peruvian upwelling regime

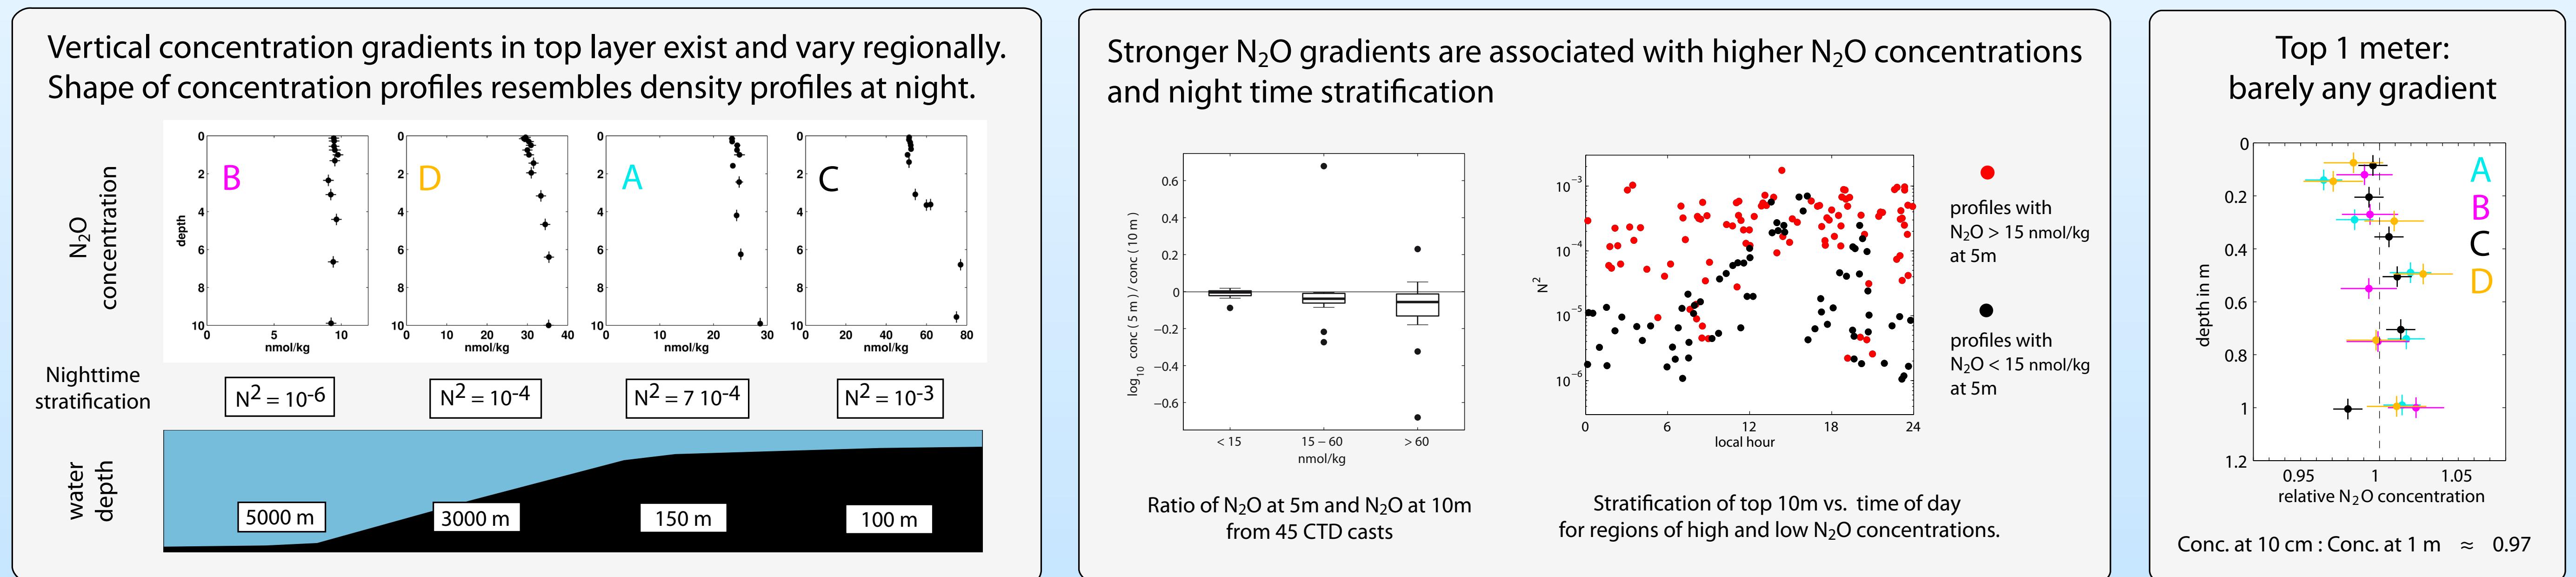

T. Fischer, A. Kock, D.L. Arévalo-Martínez, M. Dengler, P. Brandt, H.W. Bange

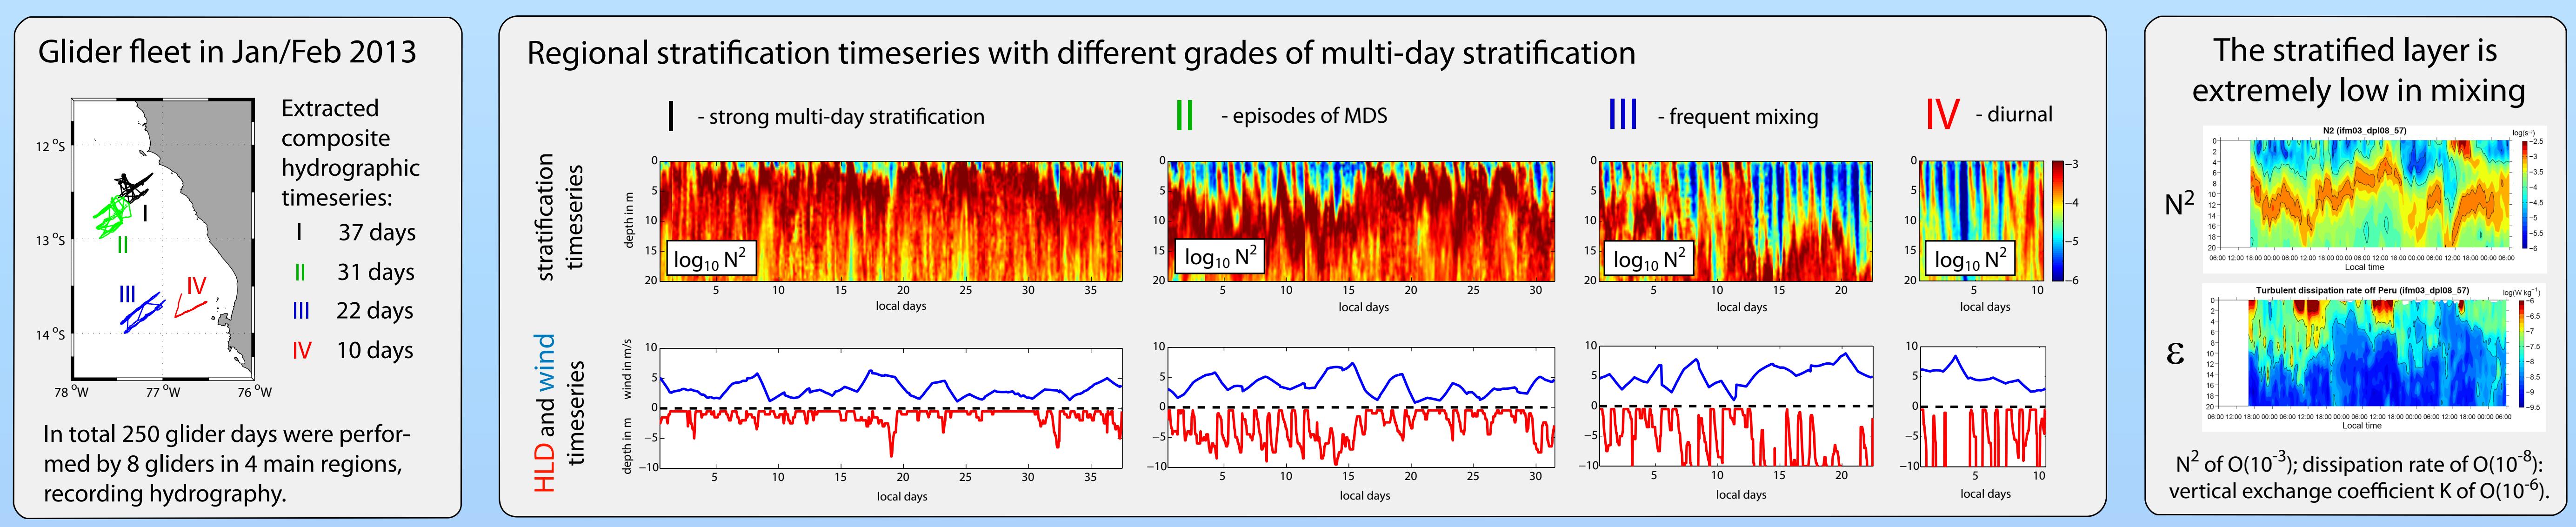

## Measuring nitrous oxide (N<sub>2</sub>O) in the top 10 meters of the Peruvian upwelling

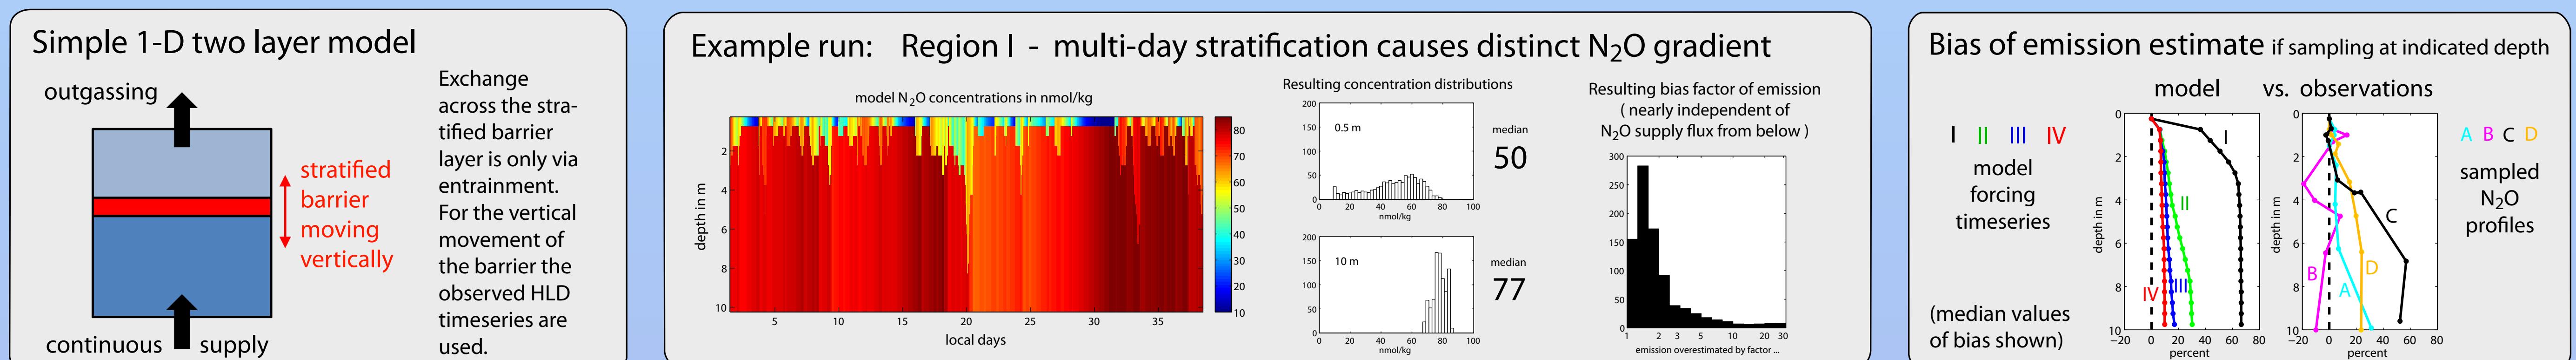

## Near-surface N<sub>2</sub>O gradients exist - associated with shallow nighttime stratification

## Existence of multi-day near-surface stratification is verified by glider surveys

## A 1-D model constrained by the glider timeseries can reproduce the N<sub>2</sub>O gradients

**Conclusion:** Not just diurnal but multi-day stratification seems the necessary condition here causing considerable near-surface N<sub>2</sub>O gradients and bias of emission estimates.

## Acknowledgements

This study was supported by the German Federal Ministry of Education and Research through the joint project SOPRAN (Surface Processes in the Anthropocene) under grant no. SOPRAN II FKZ 03F0611A and SOPRAN III FKZ 03F0662A. --- The friendly support of all crew members of research vessel METEOR during cruise M91 is highly appreciated. Particular thanks to Rudi Link for helping to construct the sampling equipment, and to the heartbeaten who sampled N<sub>2</sub>O during long hours in the dinghy, drifting in the waves while sacrificing their health. Thanks to Gerd Krahmann who processed the glider hydrographic data. The daily ASCAT global wind field data were provided by A. Bentamy and D. Croze-Fillon of Ifremer, France.
