## Foreword

Siberia's forest sector is a topic which recently has gained considerable international interest.

IIASA, the Russian Academy of Sciences, and the Russian Federal Forest Service, in agreement with the Russian Ministry of the Environment and Natural Resources, signed agreements in 1992 and 1994 to carry out a large-scale study on the Siberian forest sector. The overall objective of the study is to focus on policy options that would encourage sustainable development of the sector. The goals are to assess Siberia's forest resources, forest industries, and infrastructure; to examine the forests' economic, social and biospheric functions; with these functions in mind, to identify possible pathways for their sustainable development; and to translate these pathways into policy options for Russian and international agencies.

The first phase of the study concentrated on the generation of extensive and consistent databases of the total forest sector of Siberia and Russia.

The study is now working on its second phase, which will encompass assessment studies of the greenhouse gas balances, forest resources and forest utilization, biodiversity and landscapes, non-wood products and functions, environmental status, transportation infrastructure, forest industry and markets, and socio-economics.

This report, carried out by Prof. Shvidenko, Dr. Venevsky and Prof. Nilsson of the study's core team, is a contribution to the analyses of the topics of greenhouse gas balances and forest resources, and forest utilization.

# Increment and Mortality for Major Forest Species of Northern Eurasia with Variable Growing Stock

and Sten Nilsson*

## 1. Introduction

Current net and gross increments of the stands are the most important biometric indexes, reflecting recent productivity of forests. These indexes are necessary for numerous applications of general ecological analyses (estimation of bioproductivity and elements of global biogeochemical cycles, such as carbon and water cycles), and for analysis of sustainable wood supply.

These are the reasons for the development of a modeling system (MS) with the objective to evaluate current increment (net and gross increment) and mortality in the forests of the Former Soviet Union (FSU). With this purpose in mind, the general structure of the modeling system developed by IIASA's Siberian Forest Study has previously been presented by Shvidenko *et al.* (1995). The modeling system can be used within the framework of the Russian forest inventory system, with respect to aggregated estimates of forest productivity for different purposes.

The system describes the age dynamics of major biometric indexes for stands over site indexes (bonitäts), namely :

- height -  $H(A,N)$ ;
- diameter -  $D(A,N)$ ;
- basal area -  $BA(A,N)$ ;
- growing stock  $GS(A,N)$ ;
- total volume  $TV(A,N)$ ;
- net increment  $dGS(A,N)$ ;
- gross increment  $dTV(A,N)$ ;
- mortality  $M(A,N)=dTV(A,N) - dGS(A,N)$ ;
- percent age of net increment  $pGS(A,N)=(dGS(A,N)/GS(A,N))*100$ ;

- percent age of gross increment  $pTV(A,N)=(dTV(A,N)/TV(A,N))*100$ ;
- percent age of mortality  $pM(A,N)=(M(A,N)/GS(A,N))*100$ ;

A represents the age of the stand, and N is the site index of the stand (there are seven major site indexes in the Russian classification). The exact definitions of the indexes are presented in Appendix 1. These biometric indexes allow us to describe the temporal dynamics of stands at a satisfactory level.

The first step of the development of the modeling system was the construction of mathematical models of fully-stocked stands for the 17 major forest species in the territory of Northern Eurasia. The models are described in Shvidenko, et al. (1996).

Despite the importance of models and yield tables representing fully-stocked stands, such models can only give a generalized understanding of the growth potential for so-called “normal” stands, i.e., the most productive and even aged stands. However, huge areas of the forested territories in Northern Eurasia, especially in Siberia and the Far East, are covered by stands with variable age structures. These stands are partly mixed and are growing in conditions with natural and artificial disturbances of various intensity and frequency.

This paper summarizes the second stage of the development of the modeling system, devoted to the estimation of increment and mortality in stands with variable growing stock in the territory of Northern Eurasia.

It has been possible to estimate the biometric indexes for six species with variable growing stock levels. They are :

CONIFEROUS:

PINE,  
 SPRUCE  
 LARCH;

HARD DECIDUOUS:

OAK.

SOFT DECIDUOUS :

BIRCH,  
 ASPEN;

The above species cover nearly 85% of the Russian forested areas.

## 2. Basic Approach and Basic Materials

Development of a stand is a complex process, dependent on climatic and edaphic growing conditions, on the initial inner structure of the forest biogeocenosis, and directions and intensity of biotic and abiotic processes in the forest ecosystem. Attempts for a unified description of these complex processes, with different levels of generalizations, are given by local and general yield tables for fully-stocked stands and for stands with different stocking, as well as in different analytical and simulation models. Much discussion has been carried out concerning the problem of current Russian increment estimations (see reviews in Anatanaitis and Zagreev, 1981; Anuchin, 1977).

The first attempt to estimate the current Russian increment of stands with different stocking levels began with the famous Gerkhard formula (Anatanaitis and Zagreev, 1981):

$$dTV(d)=dTV(1.0)*(2.0-1.0*d)*d \quad (1)$$

for shade tolerant species, where  $d$  is stocking level and  $dTV(1.0)$  is the current increment for the fully-stocked stand, and

$$dTV(d)=dTV(1.0)*(1.7-0.7*d)*d \quad (2)$$

for shade intolerant species.

It is obvious that such formulas are very rough. Subsequent investigations have been oriented to search for more adequate model approaches for the current increment estimations (Anatanaitis and Zagreev, 1981). One of the first major efforts to estimate the current increment in Russia was carried out by Naumenko (1941). This Russian forester elaborated tables of current increment as functions of age for different forest species, site indexes, and stocking levels, based on data from 2327 experimental plots with 15700 felled and measured representative trees for the central part of European Russia.

Similar investigations were carried out in Lithuania (Anonymous, 1967; Anonymous, 1972), in other parts of European Russia (Zagreev, 1968), in Ukraine (Nikitin, 1966; Shvidenko *et al.*, 1987) and in Siberia (Verkhunov, 1975). The common conclusion was, that models of the current temporal increment dynamics should be elaborated by forest species, growing conditions (forest types and site indexes), types of stand age and morphological structure, types of management regimes and frequencies and intensities of disturbances (especially in Siberia and the Far East). It was also shown, that the relative current increment for given species with equal site indexes and equal stocking levels vary only slightly with the geographical location.

The most important conclusion was that, by using the forest parameters listed in the previous paragraph, there is the possibility to design relevant models (tables) of the current increment dynamics for a defined stand with an accuracy of  $\pm 25-30\%$ . It means, that such

tables give relatively good estimates on the productivity characteristics for unified stands, i.e., for aggregated estimates of productivity over huge territories.

Nevertheless, in the beginning of the work carried out within the framework of the IIASA Siberian Forest Study, different models and tables on the current increment estimations were only available for some areas of Russia, mainly for European Russia and some former Soviet Republics, also located in Europe. These models and tables were, as a rule, of limited applicability for the Siberian Forest Study and contained either estimates of net current increment or estimates of gross current increment.

The objective of the current work was to design a unified model approach, based on all existing increment data in Russia, in order to estimate net and gross increments and mortality.

The major forest species, described in this work, cover huge territories and grow in different edaphic and climatic conditions. Models and tables, presented below are, to a major extent, based on even aged single-species stands (no more than 20% is represented by non-dominant species), which are managed under specific management regimes. We assume smooth dynamics for the development of the stocking levels without any great increases or catastrophic declines. Applications of the models are relevant for static evaluations at fixed ages, but also for description of the growth processes by integrating the dGS (net increment) and the dTV (gross increment) over age, at variable stocking levels, and for specified site indexes.

In our work we used the following major sources for the initial data:

1) General tables of gross increments for stands with different stocking levels of Pine, Spruce, Birch, Aspen. (Table 147, Zagreev *et al.*, 1992). The age span of these tables is from 5 to 100 years, site indexes vary from 1a to 5a, and the stocking level varies from 0.4 to 1.0.

2) Yield tables for stands in Lithuania with different stocking levels by different types of forest of Pine, Spruce, Birch, Aspen (Tables 2.1-2.4, 2.8-2.11, 2.16-2.19, 2.24-2.27, 2.32-2.35 Kenstavichus *et al.* 1981). The age span for these tables is from 10 to 130 years, site indexes vary from 1 to 5, and the stocking level varies from 0.6 to 1.0. Total volume estimates are absent.

3) Tables of gross increment for stands in European Russia with different stocking levels of Pine, Spruce, Oak, Birch, Aspen (Tables 93-102, Tiurin *et al.*, 1945). The age span of these tables is from 10 to 90 years, site indexes vary from 1 to 4, and the stocking level varies from 0.6 to 1.0

4) Yield tables for model stands for Larch and Pine in different regions of Siberia (Tables 1-5, 11-18, 28-30, 40-52, 58, 83-86, Falaleev *et al.*, 1975). The age span of these tables varies from 20 (50) to 140 (200) years, site indexes from 3 to 5a, and the stocking level varies from 0.4 to 0.7. Estimates of the total volumes are absent as a rule. Total volume estimates are only presented in tables for Larch stands in Northern Yakutia and Buriatia.

5) Yield tables for model Larch stands in the Far East (Tables 150, 151, 153, Koriakin, 1990). The age span of these tables varies from 20 to 240 years, site indexes from 3 to 5a, and the stocking level varies from 0.4 to 0.8. Estimates of the total volumes are

absent as a rule. Total volume estimates are presented only in tables for Larch stands in the Magadan region.

6) Dynamics of the relative current increment for Larch stands in the Southern Far East (Table 158, Koriakin, 1990). The age span of this table varies from 50 to 210 years, site indexes from 1 to 5a, and the stocking level varies from 0.3 to 0.9.

For definitions of general tables, regional tables, model tables, growth tables etc., see Appendix I.

### 3. General Approach for Calculation of Three-Dimensional Functions for Biometric Indexes

#### 3.1. Calculation of the Growth Functions

The Mitcherlich (Richard-Chapman) growth function was chosen as the basic mathematical function for employing experimental data, and forming yield tables into a simple, but adequate modeling system. The growing stock, total volume and their derivatives, such as annual gross increment, annual net increment and natural mortality, as well as the percentages of these parameters are dependent on the stand age ( $A$ ) and the three different coefficients in the Mitcherlich function ( $c_1, c_2, c_3$ ). For example, total volume ( $TV$ ) can be calculated as:

$$TV = c_1 \cdot (1 - \exp(-c_2 \cdot A))^{c_3} \quad (3)$$

The coefficients have explicit biological meanings ( $c_1$  is the maximal value of the growth function (the asymptote),  $c_1 \cdot c_2 \cdot (1 - \frac{1}{c_3})^{(c_3-1)}$  is the maximal increment value (slope of the curve) and  $\frac{\ln(c_3)}{c_2}$  is the turning point of the growth function).

Using the estimates of the coefficients of the Mitcherlich function, it is possible to calculate annual increments and percentages of annual increments. For example, for the gross increment ( $dTV$ ) and the percentage of the gross increment  $P_{TV}$  we get:

$$dTV = c_1 \cdot c_2 \cdot c_3 \cdot (1 - \exp(-c_2 \cdot A))^{(c_3-1)} \cdot \exp(-c_2 \cdot A) \quad (4)$$

and

$$P_{TV} = c_2 \cdot c_3 \cdot \exp(-c_2 \cdot A) / (1 - \exp(-c_2 \cdot A)) \quad (5)$$

The difference between gross increment ( $dTV$ ) and net increment ( $dGS$ ), both calculated as derivatives of the Mitcherlich function, gives us the mortality ( $dM$ ):

$$dM = dTV - dGS. \quad (6)$$

$dM$  is the natural mortality, when the stocking level is equal to 1.0 (i.e. mortality, caused by the concurrence between individual trees), and the mortality equal to the sum of natural, pathological and mechanical mortalities, when the stocking level is less than 1.0. The coefficients of the Mitcherlich function vary for different forest species and geographical locations.

For stands of different densities (stocking)  $d$ , the growth functions can be formulated as three-dimensional functions and each of the three coefficients of the Mitcherlich function will be dependent on site index ( $N$ ) and density ( $d$ ) ( $d$  has a range from 0.3 to 1.0). The most simple form of such functions, for the coefficient estimations, is a system of polynomial nonlinear equations.

As a rule, we used the quadric polynomials to design these coefficients:

$$c_i = \sum_{l=0}^2 \sum_{m=0}^2 c_{ilm} * N^l * d^m \quad (7)$$

For example, for the calculation of the total volume of Pine, these coefficients are estimated to be:

$$\begin{aligned} c_1 &= 4.174 \cdot N^2 - 66.982 \cdot N - 193.159 \cdot d^2 + 1778.316 \cdot d - 174.997 \cdot d \cdot N + 207.467 \\ c_2 &= (0.034 \cdot N^2 - 0.430 \cdot N + 0.362 \cdot d^2 - 2.136 \cdot d + 0.113 \cdot d \cdot N + 4.285) / 100 \\ c_3 &= (0.389 \cdot N^2 - 2.872 \cdot N + 8.230 \cdot d^2 - 12.963 \cdot d + 0.776 \cdot d \cdot N + 27.684) / 10 \end{aligned} \quad (8)$$

### 3.2. Calculation of the Gross Increment Dependency on the Growing Stock Level

Based on the availability and the characteristics of the initial data, the following approach has been used.

- 1) A non-linear regression with the Levenberg-Marquart method is executed in order to estimate the coefficients of the Mitcherlich function by age, site index and stocking variations, assuming functional dependence (4) for the gross increments. The computer exercises have shown that the estimation of the exponential coefficient is particularly important, as all the functions designed are very sensitive to variation of this coefficient.
- 2) Quadratic regressions give us a statistical dependence of the three coefficients by site indexes and stockings. This stage allows us to design a three-dimensional growth function for total volume by age, site index and stocking. There are possibilities to use other non-linear expressions for the regression calculations. However, more sophisticated regressions can generate considerable calculation errors and do not coincide with the simplicity and transparency of the developed system. The analyses so far, showed that linear regressions can not be used due to the low accuracy of the results, while quadric regressions seem to give adequate results.
- 3) Finally, all total volume and gross increments functions generated, are evaluated by experts with respect to the stand variables employed in the functions. The statistical characteristics of all the approximations are checked. The procedure of checking includes comparisons with general tables for fully-stocked stands. The iterative procedure described can be restarted if the results are not explicit enough, or are in contradiction with, logical requirements of the process described.

It should be noted, that one can use the designed three dimensional total volume functions by age, site index and stocking for estimation of total volumes, gross increments and percentages of gross increment of biologically similar forest species. From the experimental data, the growing stock can be calculated by using the basal areas (BA) from fully-stocked stands evaluated in the previous steps of this study (Shvidenko *et al.*, 1996).

However, usually the stocking variations for a separate region are very small and one is forced to find separate specific methods for the construction of the final three-dimensional approximated surface. From a mathematical point of view, this is a problem of the multidimensional approximation of the plane with irregular points by an analytical function. Such a problem can only be solved, in some cases, with a "good" configuration of experimental data sets.

Computer analyses for two coniferous species (Larch and Pine) allow us to conclude that such manipulations can be made within the limits of the accuracy of the function coefficients.

This is very important, as the data for Larch gross and net increments over different growing stock levels are rather poor, and Larch is the most common forest species in the territory of the former USSR.

### 3.3. Calculation of the Net Increment Dependency on the Growing Stock Level

Basically, it can be assumed that the dependency of growing stock by the growing stock level  $d$  can be calculated in the following way:

$$GS(d) = d*GS(1.0) \quad (9)$$

where,  $GS(1.0)$  is the growing stock of completely fully stocked stands, estimated from the general tables (Shvidenko *et al.*, 1996), and  $d$  is the stocking level.

The net increment in this case could be assumed as a linear function over the stocking level:

$$dGS(d) = d*dGS(1.0) \quad (10)$$

where,  $dGS(1.0)$  is the net increment of a fully stocked stand estimated from general tables (Shvidenko *et al.*, 1996).

However, analyses of experimental data for real stands e.g., in Latvia (Kenstavichus *et al.*, 1981) have shown, that the dependence of growing stock on the stocking level can differ from a linear approach. Hence, the net increment will not have a simple linear behavior over the stocking level (as the time derivatives from the growing stock).

To construct the functions  $GS(A,d)$  and  $dGS(A,d)$  for some of the forest species we used the following equation, presented by Kenstavichus *et al.* (1981):

$$H(d) = H_B*(e*d + f) + g*(d_B - d) \quad (11)$$

where  $d$  is a stocking level, ranging from 0.3 to 1.0;  $d_B$  is the basic stocking level, which is averaged for sample plots in investigated stands;  $H_B$  is an averaged height of stands with the stocking level  $d_B$ , which is actually averaged for sample plots in investigated stands;  $e, f$  and  $g$  are regression coefficients.

We used the basic stocking levels and regression coefficients presented for different species in the above mentioned work (Kenstavichus *et al.*, 1981). Hence, the basic stocking level shown in this study is the same for all species (0.7).

It can easily be seen that the expression (11) assumes:

$$e * d_B + f = l \quad (12)$$

Therefore, the average height of a stand over stocking levels can be expressed as a linear function by the average height of a fully-stocked stand:

$$H(d) = A(d) * H(1.0) + B(d) \quad (13)$$

where:

$$A(d) = \frac{e * (d - d_B) + 1}{(1 - d_B) * e + 1} \quad (14)$$

and:

$$B(d) = g * ((d - d_B) - A(d) * (1 - d_B)), \quad (15)$$

The above mentioned Lithuanian authors proposed to estimate the growing stock of a stand by using a quadratic regression:

$$GS(d) = (C_1 + C_2 * H(d) + C_3 * H^2(d)) * d \quad (16)$$

However, this formula assumes linear dependency of the stand's basal area over the averaged height and seems to be too rough for our purposes. Therefore, we applied a cubic regression function to estimate the growing stock:

$$GS(d) = (C_1 + C_2 * H(d) + C_3 * H^2(d) + C_4 * H^3(d)) * d \quad (17)$$

The final equation for calculation of the growing stock dependency over stocking levels will be the following:

$$GS(d, Age) = d * GS(1.0, Age) + \Delta GS(d, Age), \quad (18)$$

where  $(A)$  is the age of a stand and the last term presents a nonlinear variation for the approximate formula (9). Formula 18 can be calculated as:

$$\Delta GS(d, A) = d * (q_0(d) + q_1(d) * H(1.0, A) + q_2(d) * H^2(1.0, A) + q_3(d) * H^3(1.0, A)), \quad (19)$$

where

$$\begin{aligned} q_0(d) &= C_2 * B(d) + C_3 * B^2(d) + C_4 * B^3(d), \\ q_1(d) &= C_2 * (A(d) - 1) + 2 * C_3 * A(d) * B(d) + 3 * C_4 * A(d) * B^2(d), \\ q_2(d) &= C_3 * (A^2(d) - 1) + 3 * C_4 * A^2(d) * B(d), \\ q_3(d) &= C_4 * (A^3(d) - 1), \end{aligned} \quad (20)$$

where  $A(d)$  and  $B(d)$  are calculated by formulas 14, 15 and  $C_i$  are the regression coefficients in formula 17.

Taking into account formulas 18 and 19 we can estimate the net increment over different stocking levels:

$$\frac{dGS(d, Age)}{dAge} = d * \frac{dGS(1.0, Age)}{dAge} + \frac{d(\Delta GS(d, Age))}{dAge}, \quad (21)$$

where

$$\begin{aligned} \frac{d(\Delta GS(d, Age))}{dAge} &= d * (q_1(d) * \frac{d(H(1.0, Age))}{dAge} + 2 * q_2(d) * H(1.0, Age) * \frac{d(H(1.0, Age))}{dAge} + \\ &+ 3 * q_3(d) * H^2(1.0, Age) * \frac{d(H(1.0, Age))}{dAge}) \end{aligned} \quad (22)$$

It means that we can design the net increment functions over different stocking levels if we have regression equation 15 and growth functions over average height for fully-stocked stands.

The estimates of coefficients  $e$ ,  $f$  and  $g$  for the different species in equation 9 are shown in the Table 1.

<b>Species</b>	<b>e</b>	<b>f</b>	<b>g</b>
PINE	0.125	0.912	0
SPRUCE	-0.05	1.035	-1.25
BIRCH	0.140	0.902	0
ASPEN	0.1	0.93	0
OAK	0.429	0.7	0

Table 1. The coefficients of height dependency of stocking levels.

The calculations of the net increment dependency over stocking levels showed that the overall procedure of estimation is very sensitive to the estimate of the above coefficients. The coefficients  $e$ ,  $f$  and  $g$  for pine, spruce and birch were taken directly from Table 2.55 by Kenstavichus *et al.* (1981). The coefficients for oak and aspen were estimated from tables for model stands, presented in the same book.

## 4. Results

The results presented below include coefficients of the models and tables of stand characteristics by different site indexes and stockings for Pine, Spruce, Larch, Oak, Birch and Aspen.

The following stand characteristics are presented:

1. growing stock  $GS(A, N, d)$ ,
2. total volume  $TV(A, N, d)$ ,
3. net increment  $dGS(A, N)$ ;
4. gross increment  $dTV(A, N)$ ;
5. mortality  $dM(A, N, d) = dTV(A, N, d) - dGS(A, N, d)$ ;
6. percentage of net increment  $pGS(A, N, d) = (dGS(A, N, d) / GS(A, N, d)) * 100$ ;
7. percentage of gross increment  $pTV(A, N, d) = (dTV(A, N, d) / TV(A, N, d)) * 100$ ;
8. percentage of mortality  $pM(A, N, d) = (M / GS) * 100$ ;

The estimates presented were validated based on some limited experimental data and rather numerous yield tables of model (real) stands. Unfortunately, the major part of the model yield tables, generated during the last decades in the former USSR, do not include data on the total productivity, and experimental data is absent for some parts of the distribution areas of the species studied. However, we consider the results presented as a unified modeling aggregation of existing knowledge with limitations based on the initial data. The complete tables generated from this approach are presented in Appendix 2.

# Appendix 1

## Definitions

In the following we present definitions of some terms which are central in the paper.

$GS(A)$  - **growing stock** at age  $A$ , amount of the total stem volume of all living trees of a stand, expressed in  $m^3$  per hectare.

$TV(A)$  - **total volume** (total production) by age  $A$ , total volume produced of all stem wood by a stand up to age  $A$ , expressed in  $m^3$  per hectare.

$M(A)$  - **accumulated mortality**, the accumulated stem volume of trees which died of natural causes up to age  $A$ , expressed in  $m^3$  per hectare. Hence,

$$TV(A) = GS(A) + M(A).$$

$dTV(A)$  - **gross increment** per year at age  $A$ , is defined as:

$$dTV(A) = TV(A) - TV(A-1),$$

or

$$dTV(A) = f'(A),$$

where  $TV(A) = f(A)$  is the functional expression for the total volume by age.

$dGS(A)$  - **net increment** per year at age  $A$ , is defined as :

$$dGS(A) = GS(A) - GS(A-1),$$

or

$$dGS(A) = g'(A),$$

where  $GS(A) = g(A)$  is the functional expression for the growing stock by age.

$dM(A)$  - **mortality** per year for age  $A$  is the difference between gross and net increment

$$dM(A) = dTV(A) - dGS(A).$$

**Gross increment** per year as percent of total production to date can be approximately calculated as:

$$P_{TV}(A) = \frac{dTV(A) \cdot 200}{TV(A) + TV(A-1)},$$

or explicitly as:

$$P_{TV}(A) = \frac{f'(A) \cdot 100}{f(A)}$$

**Net increment** per year, as percentage of growing stock to date, can be calculated in the same manner.

**The average diameter D** is DBH, calculated as the average quadratic value of DBH's of the trees constituting a stand.

**The average height H** is the value, calculated from the regression equation as the height of the tree with the diameter equal to D.

**Basal area BA** is the sum of areas of all trees in the stand at breast height, expressed in m<sup>2</sup> per hectare.

**Density or stocking** is determined as the ratio between the sum of the basal areas of the measured stand at breast height and the sum of the basal areas of an ideal stand according to yield tables.

**Site indexes** are determined in Russia by average height at a certain age of stands.

**Type of age structure (TASS)** is a classification system of stands, which reflect the variation of age inside a separate stand.

**General tables** are yield tables for fully stocked stands for an entire area, dominated by a certain species and are valid for all of the former USSR. They are used as general standards for different comparisons, and for forest inventories and forest management, if regional tables are absent.

**Regional tables** are yield tables generated for a specified area which is dominated by a certain species. There are different types of regional tables: for normal (or fully stocked stands); for model (or not fully stocked stands), for different TASS; for specific goals of the forest management (so-called goal programs of forest regeneration); for forest plantations with different initial densities; etc. They are used for the local forest inventory and by the forest management.

**Growth tables (or models)** are regional tables (or models) of dependency of net or/and gross growth of different stand characteristic.

## **Appendix 2**
