# First Report of the Regular Limnological Survey of Lake Biwa (Oct. 1965-Dec. 1966)

## IV. Beothos

By

Norio SUZUKI and Syuiti MORI

Ôtsu Hydrobiological Station, Kyoto University, Ôtsu

There are several published work on the benthic communities of Lake Biwa (Tsuda 1962, Ogino 1963, Kato 1963, Mori, Hayashi, and Higashi unpublished), but almost all of these did not include the prolonged successive investigation. The importance of role of bottom fauna in biological dynamics of lakes and as the indicator of characteristics of lakes, has long been recognized, so that the studies of quantitative as well as qualitative changes including seasonal variation in benthic communities extending over a long period of time are required in limnology.

Benthic communities in Lake Biwa are chiefly composed of Oligochaeta, Hirudinea, larvae of Chironomidae and Mollusca, if those living in very shallow littoral region are excluded. However, less informations on Oligochaeta and Hirudinea in Lake Biwa are available. Only several species of Oligochaeta have hitherto been identified by Yamaguchi (1964) : *Criodrilus bathybrates* Stephenson, *Kawamuria japonica* Stephenson, *Brachiura sowerbyi* Beddard, *Limnodrilus grandisetosus* Nomura, *Limnodrilus* sp., *Tubifex* sp.. Besides these, many other species including new species or endemic species of Oligochaeta will be expected to be found in this lake. Few species of Hirudinea were known, that is, *Mimobdella japonica* Blanchard, *Erpobdella* sp., *Glossiphonia* sp., *Helobdella* sp., and about thirty species of Chironomidae were recognized in Lake Biwa by Kato (1962). Fresh water Mollusca has been investigated rather in detail and about fourty species could be found in this lake.

Our survey points and conditions at these points were sketched in Part 1 "General Remark". The 15 × 15 cm Ekman-Birge sampler was used to obtain bottom sample and repeated thrice at each station. The samples were washed in a screen of about eight meshes per centimeter and all organisms removed

were put into small tubes containing 70% of alcohol solution for fixation and preservation.

Identification of Mollusca was made by Mori and that of *Chironomus* and other animals by Suzuki. We must here express our most grateful thanks to Mr. R. Kitagawa, teacher of Komono High School, Mie prefecture, for his kind initiation for identification of Chironomidae. Identification of Oligochaeta and Hirudinea was not made in this report, because of lack of our present knowledge, especially the former was due to taxonomical difficulty. After identification, all organisms were counted and weighted (in fresh) and some were measured the lengths (in the present paper, lengths measured are not shown). The number and total weights are shown in the following table. The number of individuals of Oligochaeta could not always be counted, because they were often cut into small pieces. Average values of numbers of individuals/m<sup>2</sup> and fresh weights/m<sup>2</sup> were generally calculated from three samples (sometimes from two or one samples available). After examining these data the authors consider that the sample size seems to be rather small to estimate exactly the value of standing crop in the area where the samples were collected, however they may be useful for investigating the general trend in variation covering long period. The numbers of pupae of Simuliidae and eggs of some animals could not be obtained in average values of individuals/m<sup>2</sup> and of fresh weight/m<sup>2</sup>, because they were only found attached to the shells of Mollusca.

Discussions on this investigation will be made after accumulating 2 or 3 year's data.

Results of these observations are shown in the following tables.

The “—” mark means no specimens were collected and the “×” means samples were missed at those time.

\* : These were adhered to the shell of Mollusca ? : Could not count
