#### Abstract

Let $n$ be a positive integer and $\mathcal{M}$ a set of rational $n \times n$-matrices such that $\mathcal{M}$ generates a finite multiplicative semigroup. We show that any matrix in the semigroup is a product of matrices in $\mathcal{M}$ whose length is at most $2^{n(2 n+3)} g(n)^{n+1} \in 2^{O\left(n^{2} \log n\right)}$, where $g(n)$ is the maximum order of finite groups over rational $n \times n$-matrices. This result implies algorithms with an elementary running time for deciding finiteness of weighted automata over the rationals and for deciding reachability in affine integer vector addition systems with states with the finite monoid property.

## 1 Introduction

## The Burnside Problem

An element $g$ of a semigroup $G$ is called torsion if $g^{i}=g^{j}$ holds for some naturals $i<j$, and $G$ torsion if all its elements are torsion. Burnside [6] asked in 1902 a question which became known as the Burnside problem for groups: is every finitely generated torsion group finite? Schur [28] showed in 1911 that this holds true for groups of invertible complex matrices, i.e., any finitely generated torsion subgroup of $G L(n, \mathbb{C})$ is finite. This was generalised by

Kaplansky [21, p. 105] to matrices over arbitrary fields. The Burnside problem for groups has a negative answer in general: in 1964 Golod and Shafarevich exhibited a finitely generated infinite torsion group $[13,14]$.

## The Maximal Order of Finite Matrix Groups

Schur's result [28] assures that finitely generated torsion matrix groups are finite, but does not bound the group order. Indeed, it is easy to see that any finite cyclic group is isomorphic to a group generated by a matrix in $G L(2, \mathbb{R})$. The same is not true for $G L(n, \mathbb{Q})$ : An elementary proof, see e.g. [23], shows that any finite subgroup of $G L(n, \mathbb{Q})$ is conjugate to a finite subgroup of $G L(n, \mathbb{Z})$. Another elementary proof shows that the order of any finite subgroup of $G L(n, \mathbb{Z})$ divides $(2 n)$ !; see, e.g., [27, Chapter IX]. Thus, denoting the order of the largest finite subgroup of $G L(n, \mathbb{Q})$ by $g(n)$, we have $g(n) \leq(2 n)$ !. It is shown in a paper by Friedland [12] that $g(n)=2^{n} n$ ! holds for all sufficiently large $n$. This bound is attained by the group of signed permutation matrices. Friedland's proof rests on an article by Weisfeiler [34] which in turn is based on the classification of finite simple groups. Feit showed in an unpublished manuscript [9] that $g(n)=2^{n} n$ ! holds if and only if $n \in \mathbb{N} \backslash\{2,4,6,7,8,9,10\} .{ }^{1}$ Feit's proof relies on an unpublished manuscript [33], also based on the classification of finite simple groups, which Weisfeiler left behind before his tragic disappearance.

## Deciding Finiteness of Matrix Groups

Bounds on group orders give a straightforward, albeit inefficient, way of deciding whether a given set of matrices generates a finite group: starting from the set of generators, enlarge it with products of matrices in the set, until either it is closed under product or the bound on the order has been exceeded. One can do substantially better: it is shown in [2] that, using computations on quadratic forms, one can decide in polynomial time if a given finite set of rational matrices generates a finite group.

## Deciding Finiteness of Matrix Semigroups

The Burnside problem has a natural analogue for semigroups. In 1975, McNaughton and Zalcstein [26] positively solved the Burnside problem for matrix semigroups, i.e., they showed, for any field $\mathbb{F}$, that any finitely generated torsion subsemigroup of $\mathbb{F}^{n \times n}$ is finite, using the result for groups by Schur and Kaplansky as a building block. From a computational point of view, McNaughton and Zalcstein's result suggests an approach for deciding finiteness of the semigroup generated by a given set of rational matrices: finiteness is recursively enumerable, by closing the set of generators under product, as described above for groups. On the other hand, infiniteness is recursively enumerable by enumerating elements in the generated semigroup and checking each element whether it is torsion. By the contrapositive of McNaughton and Zalcstein's result, if the generated matrix semigroup is infinite, it has a non-torsion element, witnessing infiniteness. However, deciding whether a given matrix has finite order is nontrivial. Only in 1980 did Kannan and Lipton [19, 20] show that the so-called orbit problem is decidable (in polynomial time), implying an algorithm for checking whether a matrix has finite order.

[^0]Avoiding this problem, Mandel and Simon [25] showed in 1977 that there exists a function $f: \mathbb{N}^{3} \rightarrow \mathbb{N}$ such that if $S$ is a finite subsemigroup of $\mathbb{F}^{n \times n}$, generated by $m$ of its elements, and the subgroups of $S$ have order at most $g$, then $S$ has size (cardinality) at most $f(n, m, g)$. For rational matrices, one may use the function $g(n)$ from above for $g$. By making, in a sense, McNaughton and Zalcstein's proof quantitative, Mandel and Simon explicitly construct such a function $f$, which implies an algorithm, with bounded runtime, for deciding finiteness of a finitely generated rational matrix semigroup. A similar result about the decidability of this problem was obtained independently and concurrently by Jacob [18].

## Size Bounds

Unlike the function $g$ for rational matrix groups, Mandel and Simon's function $f(n, m, g)$ depends on $m$, the number of generators. This is unavoidable: the semigroup generated by the set $\left.\mathcal{M}_{m}:=\left\{\left(\begin{array}{ll}0 & i \\ 0 & 0\end{array}\right): i \in\{0, \ldots, m-1\}\right\}\right\}$ is the set $\mathcal{M}_{m}$ itself, with $\left|\mathcal{M}_{m}\right|=m$ for any $m \in \mathbb{N}$. Further, the growth in $n$ of Mandel and Simon's $f$ is, roughly, a tower of exponentials of height $n$. They write in [25, Section 3]: "However, it is likely that our upper bound $[f(n, m, g)]$ can be significantly improved."

In [4, Chapter VI], Berstel and Reutenauer also show, for the rational case, the existence of a function in $n$ and $m$ that bounds the semigroup size. They write: "As we shall see, the function [...] grows extremely rapidly." An analysis of their proof shows that the growth of their function is comparable with the growth of Mandel and Simon's function. A related approach is taken in [31]. Further proofs of McNaughton and Zalcstein's result can be found, e.g., in $[24,11,8,30]$, but they do not lead to better size bounds.

## Length Bounds

In 1991, Weber and Seidl [32] considered semigroups over nonnegative integer matrices. Using combinatorial and automata-theoretic techniques, they showed that if a finite set $\mathcal{M} \subseteq \mathbb{N}^{n \times n}$ generates a finite monoid, then for any matrix $M$ of that monoid there are $M_{1}, \ldots, M_{\ell} \in \mathcal{M}$ with $\ell \leq\left\lceil e^{2} n!\right\rceil-2$ such that $M=M_{1} \cdots M_{\ell}$; i.e., any matrix in the monoid is a product of matrices in $\mathcal{M}$ whose length is at most $\left\lceil e^{2} n!\right\rceil-2$. Note that this bound does not depend on the number of generators. Weber and Seidl also give an example that shows that such a length bound cannot be smaller than $2^{n-2}$.

Almeida and Steinberg [1] proved in 2009 a length bound for rational matrices and expressing the zero matrix: if a finite set $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ (with $n>1$ ) generates a finite semigroup that includes the zero matrix 0 , then there are $M_{1}, \ldots, M_{\ell} \in \mathcal{M}$ with $\ell \leq(2 n-1)^{n^{2}}-1$ such that $0=M_{1} \cdots M_{\ell}$. A length bound of $n^{5}$ for expressing the zero matrix was recently given in the nonnegative integer case [22]. It is open whether there is a polynomial length bound for expressing the zero matrix in the rational case.

## Our Contribution

We prove a $2^{O\left(n^{2} \log n\right)}$ length bound for the rational case:

- Theorem 1. Let $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ be a finite set of rational matrices such that $\mathcal{M}$ generates a finite semigroup $\overline{\mathcal{M}}$. Then for any $M \in \overline{\mathcal{M}}$ there are $M_{1}, \ldots, M_{\ell} \in \mathcal{M}$ with $\ell \leq 2^{n(2 n+3)} g(n)^{n+1} \in 2^{O\left(n^{2} \log n\right)}$ such that $M=M_{1} \cdots M_{\ell}$. (Here $g(n) \leq(2 n)!$ denotes the order of the largest finite subgroup of $G L(n, \mathbb{Q})$.)

The example by Weber and Seidl mentioned above shows that any such length bound must be at least $2^{n-2}$. A length bound trivially implies a size bound, and Theorem 1 allows us to obtain the first significant improvement over the fast-growing function of Mandel and Simon.

- Corollary 2. Let $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ be a finite set of $m$ rational matrices that generate a finite semigroup $\overline{\mathcal{M}}$. Then $|\overline{\mathcal{M}}| \leq m^{2^{O\left(n^{2} \log n\right)}}$.

The proof of Theorem 1 is largely based on linear-algebra arguments, specifically on the structure of a certain graph of vector spaces obtained from $\mathcal{M}$. This graph was introduced and analysed by Hrushovski et al. [17] for the computation of the Zariski closure of the generated matrix semigroup.

After the preliminaries (section 2) and the proof of Theorem 1 (section 3), we discuss applications in automata theory (section 4). In particular we show that our result implies the first elementary-time algorithm for deciding finiteness of weighted automata over the rationals.

## 2 Preliminaries

We write $\mathbb{N}=\{0,1,2, \ldots\}$. For a finite alphabet $\Sigma$, we write $\Sigma^{*}=\left\{a_{1} \cdots a_{k}: k \geq 0, a_{i} \in \Sigma\right\}$ and $\Sigma^{+}=\left\{a_{1} \cdots a_{k}: k \geq 1, a_{i} \in \Sigma\right\}$ for the free monoid and the free semigroup generated by $\Sigma$. The elements of $\Sigma^{*}$ are called words. For a word $w=a_{1} \cdots a_{k}$, its length $|w|$ is $k$. We denote by $\varepsilon$ the empty word, i.e., the word of length 0 . For $L \subseteq \Sigma^{*}$, we also write $L^{*}=\left\{w_{1} \cdots w_{k}: k \geq 0, w_{i} \in L\right\} \subseteq \Sigma^{*}$ and $L^{+}=\left\{w_{1} \cdots w_{k}: k \geq 1, w_{i} \in L\right\} \subseteq \Sigma^{*}$.

We denote by $I_{n}$ the $n \times n$-identity matrix, and by $\overrightarrow{0}$ the zero vector. For vectors $v_{1}, \ldots, v_{k}$ from a vector space, we denote their span by $\left\langle v_{1}, \ldots, v_{k}\right\rangle$. In this article, we view elements of $\mathbb{Q}^{n}$ as row vectors.

For some $n \in \mathbb{N} \backslash\{0\}$, let $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ be a finite set of rational matrices, generating a finite semigroup $\overline{\mathcal{M}}$. For notational convenience, throughout the paper, we associate to $\mathcal{M}$ an alphabet $\Sigma$ with $|\mathcal{M}|=|\Sigma|$, and a bijection $M: \Sigma \rightarrow \mathcal{M}$ which we extend to the monoid morphism $M: \Sigma^{*} \rightarrow \overline{\mathcal{M}} \cup\left\{I_{n}\right\}$. Thus we may write $M(\Sigma)$ and $M\left(\Sigma^{*}\right)$ for $\mathcal{M}$ and $\overline{\mathcal{M}} \cup\left\{I_{n}\right\}$, respectively.

We often identify a matrix $A \in \mathbb{Q}^{n \times n}$ with its linear transformation $A: \mathbb{Q}^{n} \rightarrow \mathbb{Q}^{n}$ such that $x \mapsto x A$ for row vectors $x \in \mathbb{Q}^{n}$. To avoid clutter, we extend linear-algebra notions from matrices to words, i.e., we may write $\operatorname{im} w, \operatorname{ker} w, \operatorname{rk} w$ for the image $\operatorname{im}(M(w))=\mathbb{Q}^{n} M(w)$, the kernel $\operatorname{ker}(M(w))=\left\{x \in \mathbb{Q}^{n}: x M(w)=\overrightarrow{0}\right\}$, and the $\operatorname{rank}$ of $M(w)$.

If all matrices in $M(\Sigma)$ are invertible and $M\left(\Sigma^{*}\right)$ is finite, then $M\left(\Sigma^{*}\right)$ is a finite subgroup of $G L(n, \mathbb{Q})$. For $n \in \mathbb{N}$, let us write $g(n)$ for the size of the largest finite subgroup of $G L(n, \mathbb{Q})$. As discussed in the introduction, a non-trivial but elementary proof shows $g(n) \leq(2 n)$ !, and it is known that $g(n)=2^{n} n$ ! holds for sufficiently large $n$.

## Exterior Algebra

This brief introduction is borrowed and slightly extended from [17, Section 3]. Let $V$ be an $n$-dimensional vector space over a field $\mathbb{F}$. (We will only consider $V=\mathbb{Q}^{n}$.) For any $r \in \mathbb{N}$, let $\mathcal{A}_{r}$ denote the set of maps $B: V^{r} \rightarrow \mathbb{F}$ so that $B$ is linear in each argument and further $B\left(v_{1}, \ldots, v_{r}\right)=0$ holds whenever $v_{i}=v_{i+1}$ holds for some $i \in\{1, \ldots, r-1\}$. These conditions imply that swapping two adjacent arguments changes the sign, i.e.,

$$
B\left(v_{1}, \ldots, v_{i-2}, v_{i-1}, v_{i+1}, v_{i}, v_{i+2}, v_{i+3}, \ldots, v_{r}\right)=-B\left(v_{1}, \ldots, v_{r}\right)
$$

These properties of $\mathcal{A}_{r}$ imply that, given an arbitrary basis $\left\{e_{1}, \ldots, e_{n}\right\}$ of $V$, any $B \in \mathcal{A}_{r}$ is uniquely determined by all $B\left(e_{i_{1}}, \ldots, e_{i_{r}}\right)$ where $1 \leq i_{1}<i_{2}<\ldots<i_{r} \leq n$. For any $v_{1}, \ldots, v_{r} \in V$, define the wedge product

$$
v_{1} \wedge \cdots \wedge v_{r}: \mathcal{A}_{r} \rightarrow \mathbb{F} \quad \text { by } \quad\left(v_{1} \wedge \cdots \wedge v_{r}\right)(B)=B\left(v_{1}, \ldots, v_{r}\right) .
$$

It follows from the properties of $\mathcal{A}_{r}$ above that the wedge product is linear in each argument: if $v_{i}=\lambda u+\lambda^{\prime} u^{\prime}$ then

$$
\left(\bigwedge_{1 \leq i \leq k} v_{i}\right)(B)=\lambda\left(\bigwedge_{1 \leq j<i} v_{j} \wedge u \wedge \bigwedge_{i<j \leq k} v_{j}\right)(B)+\lambda^{\prime}\left(\bigwedge_{1 \leq j<i} v_{j} \wedge u^{\prime} \wedge \bigwedge_{i<j \leq k} v_{j}\right)(B)
$$

Moreover, $\left(v_{1} \wedge \cdots \wedge v_{r}\right)(B)=0$ if $v_{i}=v_{j}$ holds for some $i, j$ with $i \neq j$.
For $r \in \mathbb{N}$ define $\Lambda^{r} V$ as the vector space generated by the length- $r$ wedge products $v_{1} \wedge \cdots \wedge v_{r}$ with $v_{1}, \ldots, v_{r} \in V$. For any basis $\left\{e_{1}, \ldots, e_{n}\right\}$ of $V$, the set $\left\{e_{i_{1}} \wedge \cdots \wedge e_{i_{r}}: 1 \leq i_{1}<\right.$ $\left.\ldots<i_{r} \leq n\right\}$ is a basis of $\Lambda^{r} V$; hence $\operatorname{dim} \Lambda^{r} V=\binom{n}{r}$. Note that $\Lambda^{1} V=V$ and $\binom{n}{r}=0$ for $r>n$. One can view the wedge product as an associative operation $\Lambda: \Lambda^{r} V \times \Lambda^{\ell} V \rightarrow \Lambda^{r+\ell} V$. Define the exterior algebra of $V$ as the direct sum $\Lambda V=\Lambda^{0} V \oplus \Lambda^{1} V \oplus \cdots$. Then also $\wedge: \Lambda V \times \Lambda V \rightarrow \Lambda V$.

It follows that for $u_{1}, \ldots, u_{r} \in V$, we have $u_{1} \wedge \cdots \wedge u_{r} \neq \overrightarrow{0}$ if and only if $\left\{u_{1}, \ldots, u_{r}\right\}$ is linearly independent. Furthermore, for $u_{1}, \ldots, u_{r}, v_{1}, \ldots, v_{r} \in V$ and $u=u_{1} \wedge \cdots \wedge u_{r} \neq \overrightarrow{0}$ and $v=v_{1} \wedge \cdots \wedge v_{r} \neq \overrightarrow{0}$, we have that $u, v$ are scalar multiples if and only if $\left\langle u_{1}, \ldots, u_{r}\right\rangle=$ $\left\langle v_{1}, \ldots, v_{r}\right\rangle$.

The Grassmannian $\operatorname{Gr}(n)$ is the set of subspaces of $\mathbb{Q}^{n}$. By the above-stated properties of the wedge product there is an injective function

$$
\iota: \operatorname{Gr}(n) \rightarrow \Lambda \mathbb{Q}^{n}
$$

such that, for all $W \in \operatorname{Gr}(n)$, we have $\iota(W)=v_{1} \wedge \cdots \wedge v_{r}$ where $\left\{v_{1}, \ldots, v_{r}\right\}$ is an arbitrarily chosen basis of $W$. Note that the particular choice of a basis for $W$ only changes the value of $\iota(W)$ up to a constant. Given subspaces $W_{1}, W_{2} \in \operatorname{Gr}(n)$, we moreover have $W_{1} \cap W_{2}=\{\overrightarrow{0}\}$ if and only if $\iota\left(W_{1}\right) \wedge \iota\left(W_{2}\right) \neq \overrightarrow{0}$.

## 3 Proof of Theorem 1

It is convenient to state and prove our main result in terms of monoids rather than semigroups:

- Theorem 3. Let $M: \Sigma^{*} \rightarrow \mathbb{Q}^{n \times n}$ be a monoid morphism whose image $M\left(\Sigma^{*}\right)$ is finite.

Then for any $w \in \Sigma^{*}$ there is $u \in \Sigma^{*}$ with $M(w)=M(u)$ and

$$
|u| \leq 2^{n(2 n+3)} g(n)^{n+1} \in 2^{O\left(n^{2} \log n\right)}
$$

With this theorem at hand, Theorem 1 follows immediately:
Proof of Theorem 1. Let $M \in \overline{\mathcal{M}}$ be an element of the semigroup generated by $\mathcal{M}$. If $M \neq I_{n}$, by Theorem $3, M$ can be written as a short product. Otherwise, $M=I_{n} \in G$, where $G=\overline{\mathcal{M} \cap G L(n, \mathbb{Q})}$ is a finite group of order at most $g(n)$. For any product $M_{1} \cdots M_{\ell}$ with $\ell>g(n)$, there are $1 \leq i<j \leq \ell$ such that $M_{1} \cdots M_{i}=M_{1} \cdots M_{j}$, and so $M_{1} \cdots M_{\ell}=$ $M_{1} \cdots M_{i} M_{j+1} \cdots M_{\ell}$. Hence, there are $\ell \in\{1, \ldots, g(n)\}$ and $M_{1}, \ldots, M_{\ell} \in \mathcal{M}$ such that $M=I_{n}=M_{1} \cdots M_{\ell}$.

Remark 4. The same argument as in the proof above shows that in a finite monoid $(H, \cdot)$, generated by $G \subseteq H$, for any $h \in H$ there are $\ell \in\{0, \ldots,|H|-1\}$ and $g_{1}, \ldots, g_{\ell} \in G$ with $h=g_{1} \cdots g_{\ell}$.

In the remainder of this section, we prove Theorem 3. We assume that $M: \Sigma^{*} \rightarrow \mathbb{Q}^{n \times n}$ is a monoid morphism with finite image $M\left(\Sigma^{*}\right)$.

### 3.1 The Maximum-Rank Case

In this subsection we prove:
Proposition 5. Suppose that there is $r \leq n$ with $\mathrm{rk} a=r$ for all $a \in \Sigma$. Let $w \in \Sigma^{*}$ with rk $w=r$. Then there is $u \in \Sigma^{*}$ with $M(w)=M(u)$ and

$$
|u| \leq 2^{2 n+3} g(n)-1 \in 2^{O(n \log n)}
$$

In this subsection we assume that $\operatorname{rk} a=r$ holds for all $a \in \Sigma$. For the proof of Proposition 5, we define a directed labelled graph $G$ whose vertices are the vector spaces im $w$ for $w \in \Sigma^{*}$ such that $\operatorname{rk} w=r$, and whose edges are triples $\left(V_{1}, a, V_{2}\right)$ such that $a \in \Sigma$ and $V_{1} M(a)=V_{2}$. Let $\left(V_{1}, a, V_{2}\right)$ be an edge; then $V_{2} \subseteq \operatorname{im} a$, but $\operatorname{dim} V_{2}=r=\operatorname{rk} a=\operatorname{dim} \operatorname{im} a$, hence $V_{2}=\operatorname{im} a$, i.e., the edge label determines the edge target. We will implicitly use the fact that any path in $G$ is determined by its start vertex and the sequence of its edge labels. Note that if $V_{1}$ is a vertex and $a \in \Sigma$, the edge $\left(V_{1}, a, \operatorname{im} a\right)$ is present in $G$ if and only if rk $V_{1} M(a)=r$ if and only if $V_{1} \cap \operatorname{ker} a=\{\overrightarrow{0}\}$.

The following two lemmas, which are variants of lemmas in [17, Section 6], are statements about the structure of $G$ in terms of its strongly connected components (SCCs).

- Lemma 6. Let $w=w_{1} \cdots w_{k}$ for $w_{1}, \ldots, w_{k} \in \Sigma^{+}$with $\operatorname{rk} w=r$ such that the $k$ vertices $\operatorname{im} w_{1}, \ldots, \operatorname{im} w_{k}$ are all in different SCCs of $G$. Then $k \leq 2\binom{n}{r}$.

Proof. Let $i \in\{2, \ldots, k-1\}$. Since $\operatorname{rk} w_{i}=r=\operatorname{rk}\left(w_{i} w_{i+1}\right)$, we have im $w_{i} \cap \operatorname{ker} w_{i+1}=\{\overrightarrow{0}\}$, thus $\iota\left(\operatorname{im} w_{i}\right) \wedge \iota\left(\operatorname{ker} w_{i+1}\right) \neq \overrightarrow{0}$. On the other hand, for any $j<i$, since $\operatorname{im} w_{i}, \operatorname{im} w_{j}$ are in different SCCs and $\operatorname{im} w_{i}$ is reachable from $\operatorname{im} w_{j}$, the vertex $\operatorname{im} w_{j}$ is not reachable from $\operatorname{im} w_{i}$; therefore we have $\operatorname{im} w_{i} \cap \operatorname{ker} w_{j} \neq\{\overrightarrow{0}\}$, thus $\iota\left(\operatorname{im} w_{i}\right) \wedge \iota\left(\operatorname{ker} w_{j}\right)=\overrightarrow{0}$. It follows that $\iota\left(\operatorname{ker} w_{i+1}\right) \notin\left\langle\iota\left(\operatorname{ker} w_{j}\right): j<i\right\rangle$. Indeed, if $\iota\left(\operatorname{ker} w_{i+1}\right)=\sum_{j<i} \lambda_{j} \iota\left(\operatorname{ker} w_{j}\right)$ for some $\lambda_{1}, \ldots, \lambda_{i-1}$ then, by linearity of the wedge product, $\iota\left(\operatorname{im} w_{i}\right) \wedge \iota\left(\operatorname{ker} w_{i+1}\right)=$ $\sum_{j<i} \lambda_{j}\left(\iota\left(\operatorname{im} w_{i}\right) \wedge \iota\left(\operatorname{ker} w_{j}\right)\right)=\overrightarrow{0}$, a contradiction.

We show by induction on $i$ that $\operatorname{dim}\left\langle\iota\left(\operatorname{ker} w_{j}\right): j \in\{1, \ldots, i\}\right\rangle \geq i / 2$ for all $i \in\{1, \ldots, k\}$. This is clear for $i=1,2$. For the induction step, we have $\operatorname{dim}\left\langle\iota\left(\operatorname{ker} w_{j}\right): j \in\{1, \ldots, i+1\}\right\rangle \geq$ $\operatorname{dim}\left\langle\iota\left(\operatorname{ker} w_{i+1}\right), \iota\left(\operatorname{ker} w_{j}\right): j \in\{1, \ldots, i-1\}\right\rangle \geq 1+(i-1) / 2=(i+1) / 2$. Hence $k / 2 \leq$ $\operatorname{dim}\left\langle\iota\left(\operatorname{ker} w_{j}\right): j \in\{1, \ldots, k\}\right\rangle \leq \operatorname{dim} \Lambda^{n-r} \mathbb{Q}^{n}=\binom{n}{r}$.

- Lemma 7. Let $a_{1} \cdots a_{k} \in \Sigma^{*}$ be (the edge labels of) a shortest path in $G$ from a vertex $\operatorname{im} a_{0}$ to im $a_{k}$. Then $k \leq\binom{ n}{r}$.

Proof. Let $i \in\{0, \ldots, k-2\}$. We have im $a_{i} \cap \operatorname{ker} a_{i+1}=\{\overrightarrow{0}\}$, thus $\iota\left(\operatorname{im} a_{i}\right) \wedge \iota\left(\operatorname{ker} a_{i+1}\right) \neq \overrightarrow{0}$. On the other hand, for any $j>i+1$, since $a_{i+1} \cdots a_{j}$ is a shortest path from $\operatorname{im} a_{i}$ to $\operatorname{im} a_{j}$, there is no edge from $\operatorname{im} a_{i}$ to $\operatorname{im} a_{j}$; therefore we have $\operatorname{im} a_{i} \cap \operatorname{ker} a_{j} \neq\{\overrightarrow{0}\}$, thus $\iota\left(\operatorname{im} a_{i}\right) \wedge \iota\left(\operatorname{ker} a_{j}\right)=\overrightarrow{0}$. It follows that $\iota\left(\operatorname{ker} a_{i+1}\right) \notin\left\langle\iota\left(\operatorname{ker} a_{j}\right): j>i+1\right\rangle$.

By induction it follows that $\operatorname{dim}\left\langle\iota\left(\operatorname{ker} a_{j}\right): j \in\{i+1, \ldots, k\}\right\rangle \geq k-i$ holds for all $i \in\{0, \ldots, k-1\}$. Hence $k \leq \operatorname{dim}\left\langle\iota\left(\operatorname{ker} a_{j}\right): j \in\{1, \ldots, k\}\right\rangle \leq \operatorname{dim} \Lambda^{n-r} \mathbb{Q}^{n}=\binom{n}{r}$.

The next lemmas discuss cycles $w \in \Sigma^{+}$in $G$, i.e., (the edge labels of) paths in $G$ such that $\operatorname{im} w \cap \operatorname{ker} w=\{\overrightarrow{0}\}$. A cycle $w$ is said to be around $\operatorname{im} w_{0}$ if $\operatorname{im} w=\operatorname{im} w_{0}$. The following lemma says, loosely speaking, that cycles around a single vertex "generate a group".

- Lemma 8. Let $w_{0} \in \Sigma^{+}$with $\mathrm{rk} w_{0}=r$, and let $P \in \mathbb{Q}^{r \times n}$ be a matrix with im $P=\operatorname{im} w_{0}$. Then for every cycle $w \in \Sigma^{+}$around $\operatorname{im} w_{0}$ there exists a unique invertible matrix $M^{\prime}(w) \in$ $G L(r, \mathbb{Q})$ such that $P M(w)=M^{\prime}(w) P$. Moreover, for any nonempty set $C \subseteq \Sigma^{+}$of cycles around $\operatorname{im} w_{0}, M^{\prime}\left(C^{+}\right)$is a finite subgroup of $G L(r, \mathbb{Q})$.

Proof. Let $w \in \Sigma^{+}$be a cycle around im $w_{0}$. Since im $P \cap \operatorname{ker}(M(w))=\{\overrightarrow{0}\}$, it follows that $\operatorname{im}(P M(w))=\operatorname{im} w=\operatorname{im} P$. So the rows of $P M(w)$ are linear combinations of rows of $P$, and vice versa, hence there is a unique $M^{\prime}(w) \in G L(r, \mathbb{Q})$ with $P M(w)=M^{\prime}(w) P$.

Let $C \subseteq \Sigma^{+}$be a nonempty set of cycles around $\operatorname{im} w_{0}$. For any $w_{1}, w_{2} \in C$ we have $M^{\prime}\left(w_{1} w_{2}\right) P=P M\left(w_{1} w_{2}\right)=P M\left(w_{1}\right) M\left(w_{2}\right)=M^{\prime}\left(w_{1}\right) P M\left(w_{2}\right)=M^{\prime}\left(w_{1}\right) M^{\prime}\left(w_{2}\right) P$, and since the rows of $P$ are linearly independent, it follows that $M^{\prime}\left(w_{1} w_{2}\right)=M^{\prime}\left(w_{1}\right) M^{\prime}\left(w_{2}\right)$. Thus, $M^{\prime}\left(C^{+}\right)$is a semigroup.

Towards a contradiction, suppose $M^{\prime}\left(C^{+}\right)$were infinite. Since the rows of $P$ are linearly independent, it follows that $M^{\prime}\left(C^{+}\right) P$ is infinite, thus $P M\left(C^{+}\right)$is infinite. Since im $w_{0}=$ $\operatorname{im} P$, there is a matrix $B \in \mathbb{Q}^{n \times r}$ with $M\left(w_{0}\right)=B P$. Since the columns of $B$ are linearly independent, the set $B P M\left(C^{+}\right)$is infinite. But this set equals $M\left(w_{0} C^{+}\right)$, contradicting the finiteness of $M\left(\Sigma^{*}\right)$. Thus the semigroup $M^{\prime}\left(C^{+}\right)$is finite. As $M^{\prime}\left(C^{+}\right) \subseteq G L(r, \mathbb{Q})$, it follows that $M^{\prime}\left(C^{+}\right)$is a finite group.

The following lemma allows us, loosely speaking, to limit the number of cycles in a word.

- Lemma 9. Let $w_{0}, w_{1}, \ldots, w_{k} \in \Sigma^{+}$such that $w_{1}, \ldots, w_{k}$ are cycles around $\mathrm{im} w_{0}$. Then there exist $\ell \leq g(n)-1$ and $\left\{u_{1}, \ldots, u_{\ell}\right\} \subseteq\left\{w_{1}, \ldots, w_{k}\right\}$ such that $M\left(w_{0} w_{1} \cdots w_{k}\right)=$ $M\left(w_{0} u_{1} \cdots u_{\ell}\right)$.

Proof. We can assume $k \geq 1$. Let $C=\left\{w_{1}, \ldots, w_{k}\right\}$. Let $P$ and $M^{\prime}(w)$ for $w \in C$ as in Lemma 8. By Lemma 8, the set $M^{\prime}\left(C^{+}\right)$is a finite subgroup of $G L(r, \mathbb{Q})$, so we have $\left|M^{\prime}\left(C^{+}\right)\right| \leq g(r) \leq g(n)$. By Remark 4, there are $\ell \leq g(n)-1$ and $u_{1}, \ldots, u_{\ell} \in C$ such that $M^{\prime}\left(w_{1}\right) \cdots M^{\prime}\left(w_{k}\right)=M^{\prime}\left(u_{1}\right) \cdots M^{\prime}\left(u_{\ell}\right)$. Since $\operatorname{im} w_{0}=\operatorname{im} P$, there is a matrix $B \in \mathbb{Q}^{n \times r}$ with $M\left(w_{0}\right)=B P$. Hence we have $M\left(w_{0} w_{1} \cdots w_{k}\right)=B P M\left(w_{1}\right) \cdots M\left(w_{k}\right)=$ $B M^{\prime}\left(w_{1}\right) \cdots M^{\prime}\left(w_{k}\right) P=B M^{\prime}\left(u_{1}\right) \cdots M^{\prime}\left(u_{\ell}\right) P=B P M\left(u_{1}\right) \cdots M\left(u_{\ell}\right)=M\left(w_{0} u_{1} \cdots u_{\ell}\right)$.

The following lemma allows us to add cycles to a word.

- Lemma 10. Let $w \in \Sigma^{+}$be a cycle in $G$. Then there exists $\rho(w) \in \mathbb{N} \backslash\{0\}$ such that $M\left(w_{0}\right)=M\left(w_{0} w^{\rho(w)}\right)$ holds for all $w_{0} \in \Sigma^{+}$with $\operatorname{im} w_{0}=\operatorname{im} w$.

Proof. Let $P \in \mathbb{Q}^{r \times n}$ be a matrix with $\operatorname{im} P=\operatorname{im} w$. By Lemma 8, there exists $M^{\prime}(w) \in$ $G L(r, \mathbb{Q})$ such that $P M(w)=M^{\prime}(w) P$ and $\left\{M^{\prime}(w)^{i}: i \in \mathbb{N}\right\}$ is a finite group. Define $\rho(w)$ to be the order of this group, i.e., $M^{\prime}(w)^{\rho(w)}=I_{r}$. Let $w_{0} \in \Sigma^{+}$with $\operatorname{im} w_{0}=\operatorname{im} w$. Since $\operatorname{im} w_{0}=\operatorname{im} P$, there is a matrix $B \in \mathbb{Q}^{n \times r}$ with $M\left(w_{0}\right)=B P$. Hence $M\left(w_{0}\right)=B P=$ $B I_{r} P=B M^{\prime}(w)^{\rho(w)} P=B P M(w)^{\rho(w)}=M\left(w_{0}\right) M(w)^{\rho(w)}=M\left(w_{0} w^{\rho(w)}\right)$.

The following lemma allows us to limit the length of paths within an SCC.

- Lemma 11. Let $a \in \Sigma$, and let $w \in \Sigma^{*}$ be a path in $G$ from $\operatorname{im} a$ such that $\operatorname{im} a$ and $\operatorname{im} w$ are in the same SCC. Then there exists $u \in \Sigma^{*}$ with $M(a w)=M(a u)$ and

$$
|u| \leq 2^{n+2} g(n)-2 \in 2^{O(n \log n)}
$$

Figure 1 Illustration of the paths $w$ and $w^{\prime}$ in Lemma 11. Edges are depicted as solid arrows, paths as dashed arrows.

Proof. For any $b_{1}, b_{2} \in \Sigma$ such that $\operatorname{im} b_{1}, \operatorname{im} b_{2}$ are in the $\operatorname{SCC}$ of $\operatorname{im} a$, let $s\left(b_{1}, b_{2}\right) \in \Sigma^{*}$ be a shortest path from im $b_{1}$ to $\operatorname{im} b_{2}$. By Lemma 7, we have $\left|s\left(b_{1}, b_{2}\right)\right| \leq\binom{ n}{r}$.

Suppose $w=a_{1} \cdots a_{k}$ for $a_{i} \in \Sigma$. For $i \in\{1, \ldots, k\}$ define the cycle $w_{i}:=s\left(a_{i}, a\right) s\left(a, a_{i}\right)$ around $\operatorname{im} a_{i}$. By Lemma 10, we have $M(a w)=M\left(a w^{\prime}\right)$ for

$$
w^{\prime}:=a_{1} w_{1}^{\rho\left(w_{1}\right)} a_{2} w_{2}^{\rho\left(w_{2}\right)} \cdots a_{k} w_{k}^{\rho\left(w_{k}\right)}
$$

For $i \in\{1, \ldots, k\}$ also define the cycle $v_{i}:=s\left(a, a_{i}\right) s\left(a_{i}, a\right)$ around $\operatorname{im} a$. Then we have:

$$
w^{\prime}=a_{1} s\left(a_{1}, a\right) v_{1}^{\rho\left(w_{1}\right)-1} s\left(a, a_{1}\right) a_{2} s\left(a_{2}, a\right) v_{2}^{\rho\left(w_{2}\right)-1} s\left(a, a_{2}\right) \cdots a_{k} s\left(a_{k}, a\right) v_{k}^{\rho\left(w_{k}\right)-1} s\left(a, a_{k}\right)
$$

Figure 1 illustrates the paths $w$ and $w^{\prime}$. Define a set of cycles $C \subseteq \Sigma^{*}$ around im $a$ by

$$
C:=\left\{a_{1} s\left(a_{1}, a\right), v_{1}, s\left(a, a_{1}\right) a_{2} s\left(a_{2}, a\right), v_{2}, \ldots, s\left(a, a_{k-1}\right) a_{k} s\left(a_{k}, a\right), v_{k}\right\} .
$$

Since $w^{\prime} \in C^{*} s\left(a, a_{k}\right)$, by Lemma 9 , there exist $\ell \leq g(n)-1$ and $u_{1}, \ldots, u_{\ell} \in C$ such that $M(a w)=M\left(a w^{\prime}\right)=M\left(a u_{1} u_{2} \cdots u_{\ell} s\left(a, a_{k}\right)\right)$. For all $v \in C$ we have $|v| \leq 2\binom{n}{r}+1 \leq 2^{n+2}$, and $\left|s\left(a, a_{k}\right)\right| \leq\binom{ n}{r} \leq 2^{n}$. Hence the lemma holds for $u:=u_{1} u_{2} \cdots u_{\ell} s\left(a, a_{k}\right)$, as $|u| \leq$ $2^{n+2}(g(n)-1)+2^{n} \leq 2^{n+2} g(n)-2$.

We are ready to prove Proposition 5.

Proof of Proposition 5. Decompose the word $w$ into $w=a_{1} w_{1} a_{2} w_{2} \cdots a_{k} w_{k}$ for $a_{i} \in \Sigma$ so that for all $i \in\{1, \ldots, k\}$ the vertices $\operatorname{im} a_{i}, \operatorname{im} w_{i}$ are in the same SCC, and for all $i \in\{1, \ldots, k-1\}$ the vertices $\operatorname{im} w_{i}, \operatorname{im} a_{i+1}$ are in different SCCs. By Lemma 6, we have $k \leq 2\binom{n}{r} \leq 2^{n+1}$. For all $i \in\{1, \ldots, k\}$, by Lemma 11, there is $u_{i} \in \Sigma^{*}$ with $\left|u_{i}\right| \leq 2^{n+2} g(n)-2$ such that $M\left(a_{i} w_{i}\right)=M\left(a_{i} u_{i}\right)$. Hence the proposition holds for $u:=a_{1} u_{1} a_{2} u_{2} \cdots a_{k} u_{k}$, as $|u| \leq 2^{n+1}\left(2^{n+2} g(n)-2+1\right) \leq 2^{2 n+3}-1$.

### 3.2 The General Case

In this subsection we prove Theorem 3. For $r \in\{0, \ldots, n\}$ let $d_{r} \in \mathbb{N}$ be the smallest number such that for any $w \in \Sigma^{*}$ with rk $w \geq r$ there is $u \in \Sigma^{*}$ with $M(w)=M(u)$ and $|u| \leq d_{r}$. Also write $h$ for the bound from Proposition 5.

- Proposition 12. For any $r \in\{0, \ldots, n-1\}$ we have $d_{r} \leq d_{r+1}+\left(d_{r+1}+1\right) h$.

Proof. Let $w \in \Sigma^{*}$ with rk $w \geq r$. We need to show that there is $u \in \Sigma^{*}$ with $M(w)=M(u)$ and $|u| \leq d_{r+1}+\left(d_{r+1}+1\right) h$. Decompose $w$ into $w=w_{0} a_{1} w_{1} a_{2} w_{2} \cdots a_{k} w_{k}$ for $a_{i} \in \Sigma$ such that $\operatorname{rk} w_{0}>r$ and for all $i \in\{1, \ldots, k\}$ we have $\operatorname{rk}\left(a_{i} w_{i}\right)=r$ and $\operatorname{rk} w_{i}>r$. (This decomposition is unique; in particular, $a_{k} w_{k}$ is the shortest suffix of $w$ with rank $r$.) By the definition of $d_{r+1}$, for all $i \in\{0, \ldots, k\}$ there exists $u_{i} \in \Sigma^{*}$ with $M\left(w_{i}\right)=M\left(u_{i}\right)$ and $\left|u_{i}\right| \leq d_{r+1}$. Then $M(w)=M\left(u_{0} a_{1} u_{1} a_{2} u_{2} \cdots a_{k} u_{k}\right)$.

Define a new alphabet $\Sigma_{r}$ and a monoid morphism $M_{r}: \Sigma_{r}^{*} \rightarrow \mathbb{Q}^{n \times n}$ with $M_{r}\left(\Sigma_{r}\right)=$ $\left\{M\left(a_{i} u_{i}\right): i \in\{1, \ldots, k\}\right\}$, and note that $\mathrm{rk} M_{r}(b)=r$ for all $b \in \Sigma_{r}$. Then there is a word $y \in \Sigma_{r}^{*}$ such that $M_{r}(y)=M\left(a_{1} u_{1} \cdots a_{k} u_{k}\right)$. By Proposition 5, there is $x \in \Sigma_{r}^{*}$ with $M_{r}(y)=M_{r}(x)$ and $|x| \leq h$. Obtain the word $v \in \Sigma^{*}$ from $x$ by replacing each letter $b \in \Sigma_{r}$ in $x$ by $a_{i} u_{i}$ for $i \in\{1, \ldots, k\}$ such that $M_{r}(b)=M\left(a_{i} u_{i}\right)$. Then $M_{r}(x)=M(v)$, and thus $M(w)=M\left(u_{0} a_{1} u_{1} \cdots a_{k} u_{k}\right)=M\left(u_{0}\right) M_{r}(y)=M\left(u_{0}\right) M_{r}(x)=M\left(u_{0}\right) M(v)=M\left(u_{0} v\right)$, where $\left|u_{0} v\right|=\left|u_{0}\right|+|v| \leq d_{r+1}+\left(d_{r+1}+1\right)|x| \leq d_{r+1}+\left(d_{r+1}+1\right) h$.

We can now prove our main result.
Proof of Theorem 3. We prove by induction that for all $r \in\{0, \ldots, n\}$ we have $d_{r} \leq$ $(h+1)^{n-r} d_{n}+(h+1)^{n-r}-1$. For the base case, $r=n$, this is trivial. For the step, let $r<n$. We have:

$$
\begin{aligned}
d_{r} & \leq h+(h+1) d_{r+1} & & \text { (Proposition 12) } \\
& \leq h+(h+1)\left((h+1)^{n-r-1} d_{n}+(h+1)^{n-r-1}-1\right) & & \text { (induction hypothesis) } \\
& =h+(h+1)^{n-r} d_{n}+(h+1)^{n-r}-h-1 & &
\end{aligned}
$$

This completes the induction proof. Hence $d_{0} \leq(h+1)^{n}\left(d_{n}+1\right)=2^{n(2 n+3)} g(n)^{n}\left(d_{n}+1\right)$. The rank- $n$ matrices in $M(\Sigma)$ generate a finite subgroup of $G L(n, \mathbb{Q})$. So it follows by Remark 4 that $d_{n}+1 \leq g(n)$. Thus $d_{0} \leq 2^{n(2 n+3)} g(n)^{n+1}$.

## 4 Algorithmic Applications

Theorem 1 gives an exponential-space algorithm for deciding finiteness of a finitely generated rational matrix semigroup. In fact, the following theorem shows that deciding finiteness is in the second level of the weak EXP hierarchy (see e.g. [16] for a definition).

- Theorem 13. Given be a finite set $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ of rational matrices, the problem of deciding finiteness of the generated semigroup $\overline{\mathcal{M}}$ is in coNEXP ${ }^{\mathrm{NP}}$.

Proof. For a NEXP ${ }^{\text {NP }}$ algorithm deciding infiniteness, non-deterministically guess in exponential time some $M=M_{1} \cdots M_{\ell}, M_{i} \in \mathcal{M}$, with $\ell=2^{n(2 n+3)} g(n)^{n+1}+1$ as a witness for infiniteness. Then, using a call to an NP oracle, check whether there are $M_{1}^{\prime}, \ldots, M_{r}^{\prime} \in \mathcal{M}$ such that $M=M_{1}^{\prime} \cdots M_{r}^{\prime}$ for some $0 \leq r<\ell$. If the call is successful then reject, otherwise accept.

Correctness of the algorithm immediately follows from Theorem 1: if $\overline{\mathcal{M}}$ is finite, then the $M_{1}^{\prime}, \ldots, M_{r}^{\prime} \in \mathcal{M}$ such that $M=M_{1}^{\prime} \cdots M_{r}^{\prime}$ are guaranteed to exist.

## 115:10 On the Size of Finite Rational Matrix Semigroups

This is the first improvement of the non-elementary algorithm of Mandel and Simon [25].
Another immediate consequence of Theorem 1 is an upper bound on the complexity of the membership problem for finite matrix semigroups:

- Theorem 14. Given a finite set of rational matrices $\mathcal{M} \subseteq \mathbb{Q}^{n \times n}$ such that $\overline{\mathcal{M}}$ is finite and $A \in \mathbb{Q}^{n \times n}$, the problem of deciding whether $A \in \overline{\mathcal{M}}$ is in NEXP.

In the remainder of this section, we discuss implications of Theorem 13 to decision problems in automata theory.

### 4.1 Weighted Automata

The motivation for Mandel and Simon to study the finiteness problem originated from investigating the decidability of the finiteness problem (originally called boundedness problem in [25]) for weighted automata. A weighted automaton over $\mathbb{Q}$ is a quintuple $\mathcal{A}=(n, \Sigma, M, \alpha, \eta)$ where $n \in \mathbb{N}$ is the number of states, $\Sigma$ is the finite alphabet, $M: \Sigma \rightarrow \mathbb{Q}^{n \times n}$ maps letters to transition matrices, $\alpha \in \mathbb{Q}^{n}$ is the initial state vector, and $\eta \in \mathbb{Q}^{n}$ is the final state vector. We extend $M$ to the monoid morphism $M: \Sigma^{*} \rightarrow \mathbb{Q}^{n \times n}$ as before. Such an automaton defines a function $|\mathcal{A}|: \Sigma^{*} \rightarrow \mathbb{Q}$ by defining $|\mathcal{A}|(w)=\alpha M(w) \eta^{T}$, where the superscript $T$ denotes transpose. We say, $\mathcal{A}$ is finite if the image of $|\mathcal{A}|$ is finite, i.e., if $|\mathcal{A}|\left(\Sigma^{*}\right) \subseteq \mathbb{Q}$ is a finite set. The finiteness problem asks whether a given automaton is finite.

It is clear that if $M\left(\Sigma^{*}\right)$ is finite then $\mathcal{A}$ is finite. The converse is not generally true: e.g., any automaton $\mathcal{A}$ whose initial state vector is the zero vector satisfies $|\mathcal{A}|\left(\Sigma^{*}\right)=\{0\}$, hence is finite, regardless of $M\left(\Sigma^{*}\right)$. However, it is argued in the proof of Corollary 5.4 in [25] that, given an automaton $\mathcal{A}$, one can compute, in exponential time, a polynomial-size automaton $\mathcal{B}$ with monoid morphism $M_{\mathcal{B}}$ such that (i) $|\mathcal{A}|=|\mathcal{B}|$, and (ii) $\mathcal{A}$ (and hence $\mathcal{B}$ ) is finite if and only if $M_{\mathcal{B}}\left(\Sigma^{*}\right)$ is finite. ${ }^{2}$ Mandel and Simon use this argument to show that the finiteness problem for weighted automata over $\mathbb{Q}$ is decidable. Theorem 13 then immediately gives:

- Corollary 15. The finiteness problem for weighted automata over $\mathbb{Q}$ can be decided in coNEXP ${ }^{\text {NP }}$.

### 4.2 Affine Integer Vector Addition Systems with States

We show that Theorem 1 together with Corollary 2 imply an upper bound for the reachability problem in affine integer vector addition systems with states with the finite monoid property (afmp- $\mathbb{Z}$-VASS) studied in [5]. An affine $\mathbb{Z}$-VASS in dimension $d \in \mathbb{N}$ is a tuple $\mathcal{V}=(d, Q, T)$ such that $Q$ is a finite set of states and $T \subseteq Q \times \mathbb{Z}^{d \times d} \times \mathbb{Z}^{d} \times Q$ is a finite transition relation. Setting $\mathcal{M}:=\left\{A \in \mathbb{Z}^{d \times d}:(q, A, \vec{b}, r) \in T\right\}$, in afmp- $\mathbb{Z}$-VASS we additionally require that $\overline{\mathcal{M}}$ is finite. A configuration of $\mathcal{V}$ is a tuple $(q, \vec{v}) \in Q \times \mathbb{Z}^{d}$ which we write as $q(\vec{v})$. We define the step relation $\rightarrow \subseteq\left(Q \times \mathbb{Z}^{d}\right)^{2}$ such that $q(\vec{v}) \rightarrow r(\vec{w})$ if and only if there is a transition $(q, A, \vec{b}, r) \in T$ such that $\vec{w}=A \cdot \vec{v}+\vec{b}$. Moreover, we denote by $\rightarrow^{*}$ the reflexive transitive closure of $\rightarrow$. For a configuration $q(\vec{v})$, we define the reachability set of $q(\vec{v})$ as $\mathcal{R}(q(\vec{v})):=\left\{r(\vec{w}): q(\vec{v}) \rightarrow^{*} r(\vec{w})\right\}$. Given configurations $q(\vec{v})$ and $r(\vec{w})$, reachability is the problem of deciding whether $r(\vec{w}) \in \mathcal{R}(q(\vec{v}))$. Note that $\mathcal{R}(q(\vec{v}))$ is in general infinite despite $\overline{\mathcal{M}}$ being finite.

[^1]The reachability problem for afmp-Z-VASS was shown decidable in [5] by a reduction to reachability in $\mathbb{Z}$-VASS. A $\mathbb{Z}$-VASS is an afmp- $\mathbb{Z}$-VASS in which every transition is of the form $\left(q, I_{d}, \vec{b}, r\right)$. The reachability problem for $\mathbb{Z}$-VASS is known to be NP-complete, see e.g. [15]. The size of the $\mathbb{Z}$-VASS obtained in the reduction given in [5] grows in $|\overline{\mathcal{M}}|$ and hence leads to a non-elementary upper bound for reachability in afmp-Z-VASS assuming Mandel and Simon's bound. The results of this paper enable us to significantly improve this upper bound.

- Corollary 16. The reachability problem for afmp-Z्Z-VASS can be decided in EXPSPACE.

Proof. Let $\mathcal{V}=(d, Q, T)$ be an afmp- $\mathbb{Z}$-VASS and let $\mathcal{M}$ be defined as above. Set $\|\mathcal{M}\|:=$ $|\overline{\mathcal{M}}| \cdot d^{2} \cdot \max \{\log (\|A\|+1): A \in \overline{\mathcal{M}}\}$, where $\|A\|$ is the largest absolute value of all entries of $A$. Since $\left\|A_{1} \cdots A_{n}\right\| \leq d^{n} \cdot\left\|A_{1}\right\| \cdots\left\|A_{n}\right\|$ for all $A_{1}, \ldots, A_{n} \in \mathbb{Z}^{d \times d}$ and $n \in \mathbb{N}$, by Theorem 1 and Corollary 2 we have

$$
\|\mathcal{M}\| \leq|T|^{2^{O\left(d^{2} \cdot \log d\right)}} \cdot d^{2} \cdot 2^{d(2 d+3)} g(d)^{d+1} \cdot(\log d+\|T\|) \leq\|T\|^{2^{O\left(d^{2} \cdot \log d\right)}}
$$

where $\|T\|:=\sum_{(q, A, \vec{b}, r) \in T} d^{2} \cdot\lceil\log \|A\|+\log \|\vec{b}\|+1\rceil$. It can be deduced from the proof of $[5$, Thm. 7] that reachability in $\mathcal{V}$ can be decided in non-deterministic space that is polynomially bounded in the encoding of $\mathcal{V}$ and poly-logarithmically in $\|\mathcal{M}\|$, from which the desired exponential space upper bound follows.

## 5 Conclusion

The main result of this paper has been to show that any element in the finite multiplicative semigroup $\overline{\mathcal{M}}$ generated by a finite set $\mathcal{M}$ of $m$ rational $n \times n$ matrices can be obtained as a product of generators of length at most $2^{O\left(n^{2} \log n\right)}$. This length bound immediately gives that $|\overline{\mathcal{M}}|$ is bounded by $m^{2^{O\left(n^{2} \log n\right)}}$.

There remain two immediate questions that we did not answer in this article. The first is whether the order of growth of $|\overline{\mathcal{M}}|$ we obtained is tight. If $\overline{\mathcal{M}}$ is a group its order can be bounded by $2^{n} n$ ! for almost all $n$, and this bound is attained by the group of signed permutation matrices. In contrast, in the semigroup case $|\overline{\mathcal{M}}|$ also depends on $m$. We conjecture that our doubly exponential upper bound is not optimal and that it is possible to establish an exponential upper bound of $|\overline{\mathcal{M}}|$ in terms of $m$ and $n$. The second open question concerns the precise complexity of deciding finiteness of matrix semigroups. We have been unable to establish any non-trivial lower bounds on this problem and conjecture that our coNEXP ${ }^{\text {NP }}$ upper bound can significantly be improved, possibly by adapting techniques of Babai et al. [2].

[^0]:    ${ }^{1}$ A list of the maximal-order finite subgroups of $G L(n, \mathbb{Q})$ for $n \in\{2,4,6,7,8,9,10\}$ can be found in [3, Table 1].

[^1]:    ${ }^{2}$ We remark that this automaton $\mathcal{B}$ has the minimal number of states among the automata defining the function $|\mathcal{A}|$. This minimal automaton goes back to [29] and has been further studied in, e.g., [7, 10].
