Autoimmune diseases are believed to be highly dependent on loss of immune tolerance to self-antigens. Currently, no treatments have been successful clinically in inducing autoantigen-specific tolerance, including efforts to utilize antigen-specific immunotherapy (ASIT) to selectively correct the aberrant autoimmunity. Soluble antigen arrays (SAGAs) represent a novel autoantigen delivery system composed of a linear polymer, hyaluronic acid (HA), displaying multiple copies of conjugated autoantigen. We have previously reported that Soluble Antigen Arrays proteolipid protein (SAGA<sub>PLP</sub>) induced tolerance to a specific multiple sclerosis (MS) autoantigen, proteolipid peptide (PLP). Utilizing SAGA technology, we have developed a new ASIT as a possible type 1 diabetes (T1D) therapeutic by conjugating human insulin to HA, known as Soluble Antigen Array Insulin (SAGA<sub>Ins</sub>). Three types were synthesized: low valency <sub>lv</sub>SAGA<sub>Ins</sub> (2 insulins per HA), medium valency <sub>mv</sub>SAGA<sub>Ins</sub> (4 insulins per HA) and, high valency <sub>hv</sub>SAGA<sub>Ins</sub> (9 insulins per HA) to determine if valency differentially modulates the *ex vivo* activity of insulin-binding B cells (IBCs). Extensive biophysical characterization was performed for the SAGA molecules. SAGA<sub>Ins</sub> molecules were successfully used to affect the biologic activity of IBCs by inducing desensitization of the B cell antigen receptors (BCR). SAGA<sub>Ins</sub> bound specifically to insulin-

LC-MS data confirming Ins-Alk was synthesized and RP-HPLC chromatograms for conjugation efficiency for <sub>mv</sub>SAGA<sub>Ins</sub> and <sub>hv</sub>SAGA<sub>Ins</sub>.

reactive B cells without blocking epitopes recognized by antibodies against the Fc regions of membrane immunoglobulin or CD79 transducer components of the BCR. Pre-incubation of IBCs (125Tg) with SAgA<sub>Ins</sub>, but not HA alone, rendered the IBCs refractory to re-stimulation. SAgA<sub>Ins</sub> induced a decrease in BCR expression and IP3R-mediated intracellular calcium release. Surprisingly, SAgA<sub>Ins</sub> binding to BCR on the surface of IBCs induced the observed effects at both high and low SAgA<sub>Ins</sub> valency. Future studies aim to test the effects of SAgA<sub>Ins</sub> on disease progression in the VH125.NOD mouse model of T1D.

## INTRODUCTION

Autoimmune diseases, such as multiple sclerosis (MS),<sup>1, 2</sup> type 1 diabetes (T1D),<sup>3-7</sup> neuromyelitis optica,<sup>8, 9</sup> and lupus erythematosus,<sup>10, 11</sup> involve loss of tolerance to self-antigens in autoreactive B cells, leading to tissue damage, disability, and death. In individuals afflicted by T1D, the insulin-producing beta cells in the pancreas are targeted by an autoimmune response, resulting in cell death.<sup>3</sup> While production of autoantibodies is a strong predictor of the development of T1D, no studies have shown such antibodies to be pathogenic. Instead, studies have suggested B cells may contribute to the development of disease via their antigen presenting function and/or cytokine production.<sup>3-7</sup> Rituximab works by depleting B cells and has been used to treat certain autoimmune disease, including T1D. However, this monoclonal anti-CD20 antibody causes global B cell depletion, increasing risk of infection, and can exhibit limited efficacy.<sup>12-14</sup> Antigen-specific immune therapy (ASIT) has emerged as a potential means to selectively induce immune tolerance,<sup>15, 16</sup> via an intervention similar to allergy shot therapies, which often use soluble antigens to restore tolerance towards specific allergens.<sup>17</sup> Since B cells specificity is determined by cell surface antigen receptors, antigen-specific strategies to selectively tolerize or delete autoreactive B cells offer a promising approach to ASIT.

In now classic studies, Dintzis and co-workers analyzed the delivery of antigens bound to polymers, and reported two different antigen-specific responses dictated by the following properties: polymer molecular weight, solubility, and antigen valency and spacing. An immunogenic response was seen when polymers delivering haptens were large (>100 kDa), rigid, and poorly soluble. A tolerogenic effect occurred when polymers delivering haptens were smaller (<100 kDa), flexible, soluble, and often with relatively lower hapten density.<sup>18-21</sup> Interestingly, the molecular properties that encourage immune tolerance are also favorable for accessing B cell compartments in secondary lymphoid organs (<100 kDa)<sup>22, 23</sup> and may promote selectivity to antigen-specific B cells over other professional antigen presenting cells (pAPCs). We hypothesized that an antigen delivery system exhibiting molecular properties capable of inducing tolerance by engaging antigen-specific B cells may be a viable therapeutic for T1D.

Our group has previously described a novel antigen delivery system known as Soluble Antigen Arrays (SAGAs), which were originally designed based on ‘Dintzis rules’. SAGAs are constructed using a hydrophilic linear polymer hyaluronic acid (HA) grafted with multiple repeating autoantigen. SAGA prototypes used proteolipid protein peptide (PLP<sub>139–151</sub>) to treat experimental autoimmune encephalomyelitis induced by this same peptide.<sup>24–32</sup> SAgA<sub>PLP</sub> suppressed disease progression in many studies of this murine model used to mimic MS in humans. Our studies indicated SAGA engagement of B cell antigen receptors (BCRs) induced anergy, a known mechanism of peripheral immune tolerance. cSAgA<sub>PLP</sub> constructed via a non-hydrolyzable linker chemistry (i.e. covalent) rather than a hydrolyzable linker (SAgA<sub>PLP</sub>) showed greater binding *in vitro* to B cells and greater disease suppression *in vivo*.<sup>31, 32</sup> In sum, SAGAs were able to target antigen-specific B cells, crosslink surface BCRs, and sustain receptor occupancy to effectively suppress autoreactive B cells.

We hypothesized that SAGAs composed of multiple human insulin molecules conjugated to HA may silence or delete B cells obtained from non-obese diabetic (NOD) mice transgenic for anti-insulin immunoglobulin heavy chain (VH125.NOD). Human insulin was conjugated onto HA using Copper-catalyzed Azide-Alkyne Cycloaddition (CuAAC) linker chemistry. Soluble Antigen Array Insulin (SAGA<sub>Ins</sub>) products with different valency were synthesized (Scheme 1) and their biophysical properties were studied. Activity of SAGA<sub>Ins</sub> was determined in B cells from both 125Tg (NOD) and VH125.NOD mice to confirm their ability to ligate BCR on the surface of insulin-specific B cells (IBCs). To further validate specificity, B cells (CD43<sup>-</sup>) purified from spleens of VH125.NOD mice and MD4 B cells (hen egg lysozyme (HEL) reactive) were mixed at approximately the same frequency as IBCs, thereby defining the ability of SAGA<sub>Ins</sub> to selectively block binding of insulin to IBCs but not HEL binding to MD4 B cells. Lastly, to determine if SAGA<sub>Ins</sub> can induce immune markers of anergy in IBCs, B cells from 125Tg mice were cultured *in vitro* with or without SAGA<sub>Ins</sub>, or HA alone. These cells were subsequently assayed for surface levels of BCR as well as other markers to determine cell stimulation or anergy.

## Experimental

**Materials**—Cell Prime™ r-insulin recombinant human insulin was purchased from EMD Millipore Corporation (Chicago, IL). *N*-(3-dimethylaminopropyl)-*N*'-ethylcarbodiimide hydrochloride (EDC), 2-(*N*-morpholino)ethane-sulfonic acid sodium salt (MES), tris(3-hydroxypropyl)triazolylmethylamine, sodium ascorbate (NaAsc), and Propargyl-*N*-hydroxysuccinimide ester were purchased from Sigma-Aldrich (St. Louis, MO) and used as received without further purification. Hyaluronic acid (HA) sodium salt (MW 16 kDa) was purchased from Lifecore Biomedical (Chaska, MN). 11-azido-3,6,9-trioxundecan-1-amine (NH<sub>2</sub>-PEG<sub>3</sub>-N<sub>3</sub>), *N*-hydroxysuccinimide, Copper (II) sulfate pentahydrate (CuSO<sub>4</sub> • 5H<sub>2</sub>O) was purchased from Acros Organics (Geel, Belgium). Alkyne-functionalized peptide bearing an *N*-terminal 4-pentynoic acid (homopropargyl, hp) modification, hpPLP<sub>139–151</sub> (hp-HSLGKWLGHDPDKF-OH) was originally synthesized in our laboratory via solid phase peptide synthesis. Larger quantities of hp PLP<sub>139–151</sub> peptide was obtained from Biomatik USA, LLC (Wilmington, DE). VH125.NOD and MD4 mice were purchased from The Jackson Laboratory and 125Tg mice were a kind gift from the laboratory of Dr. Rachel

Friedman (National Jewish Health, Department of Biomedical Research). CD43 negative selections were purchased from Miltenyi Biotec and Millipore Sigma respectively. B76 and HM79 were produced in the Cambier laboratory and were directly conjugated to fluorochromes (Thermo Fisher Scientific). 5  $\mu$ M Indo-1 acetoxymethyl calcium indicator were purchased from Molecular Probes. All other chemicals and reagents were analytical grade and used as received.

**Synthesis and Labeling of Soluble Antigen Arrays—**Soluble antigen arrays (SAGAs) were synthesized and characterized as previously reported.<sup>31, 32</sup> Protein conjugation was determined through gradient reverse-phase analytical high-performance liquid chromatography (RP-HPLC).

**Synthesis of Alkyne-Functionalized Human Insulin (Ins-Alk)—**Synthesis of *Ins-alk* was adapted from Patent No.: US 8,906,850 B2. 120.00 mg of powdered human insulin is dissolved in 3000  $\mu$ L of anhydrous DMSO at room temperature followed by the addition of 120  $\mu$ L of triethylamine (TEA). The solution is stirred for 30 min at room temperature. Next, 1.2 equivalents of Propargyl-N-hydroxysuccinimidyl ester is slowly added to the insulin-TEA solution as a 1.0 M solution of the Propargyl-N-hydroxysuccinimidyl ester in THF. The reaction is mixed for 1h and then quenched via the addition of 9.7  $\mu$ L of a stock solution containing 250  $\mu$ L of ethanolamine in 5,000  $\mu$ L of DMSO followed by mixing for five min. (37.8 mg, 30.51%); LCMS (TOF ESI+) expected [M]<sup>+</sup>: 5918.66, found: 5918.66.

**Synthesis of Azide Functionalized Hyaluronic Acid (HA-N<sub>3</sub>)—**Synthesis of HA-N<sub>3</sub> was adapted from Hu *et al* and Di Meo *et al*. Sodium hyaluronate (93.9  $\mu$ mol, 16 kDa average MW) was added to a 250 mL round bottom flask with stir bar, followed by 100 mL of 50 mM 2-(N-morpholino)ethanesulfonic acid (MES) buffer (pH = 4.0). The mixture was stirred until in solution (~15 min) before EDC (23.1 mmol) was added neat, then *N*-hydroxysuccinimide (18.8 mmol) was added neat. The mixture was stirred for 5 min before H<sub>2</sub>N-PEG<sub>3</sub>-N<sub>3</sub> (4.51 mmol) in 20 mL MES buffer was added. The solution was then stirred for 24 h at room temperature before being dialyzed in 6–8 kDa cutoff dialysis tubing against 4.5 L of 1.0 M NaCl solution for 24 h, then 4.5 L of deionized water (4  $\times$  12 hours). The volume in the bag was then transferred to vials, frozen, and lyophilized to yield a white powder (1.61 g, 95.0%).

**Synthesis of SAgA Insulin (SAgA<sub>Ins</sub>)—**Three different reactions with 5 equivalents of Ins-Alk relative to HA-N<sub>3</sub> (to make <sub>lv</sub>SAgA<sub>Ins</sub> and <sub>mv</sub>SAgA<sub>Ins</sub>) and 10 equivalents of Ins-Alk relative to HA-N<sub>3</sub> (<sub>hv</sub>SAgA<sub>Ins</sub>) were set up with the following conditions. HA-N<sub>3</sub> (0.81  $\mu$ mol) was added as a 15  $\mu$ M solution in phosphate buffer (50 mM, pH= 7.0) to a 100 mL round bottom flask with stir bar. Followed by the addition of insulin-alkyne, a 4.0 mM or 8.1 mM solution in DMF (5 and 10 equivalents relative to HA-N<sub>3</sub> respectively) was also added. Then a premixed solution of THPTA (60  $\mu$ mol) and CuSO<sub>4</sub> • 5H<sub>2</sub>O (12  $\mu$ mol) in phosphate buffer (50 mM, pH= 7.0) was added to the alkyne/azide mixture. Then a 100  $\mu$ L aliquot was removed for HPLC analysis. NaAsc (242  $\mu$ mol) was then added to the reaction mixture as a 100 mM solution in phosphate buffer (pH= 7.0). One reaction with 5 equivalence of Ins-Alk relative to HA-N<sub>3</sub> was stirred at room temperature for 24h until some alkyne component was

consumed to furnish  ${}_{1v}\text{SAgA}_{\text{Ins}}$ . While two other reactions were stirred at elevated temperature (40°C) for 24 h until all alkyne component was consumed to produce both  ${}_{mv}\text{SAgA}_{\text{Ins}}$  and  ${}_{hv}\text{SAgA}_{\text{Ins}}$ . Additional 100  $\mu\text{L}$  aliquots were removed throughout the course of the reaction to determine the extent of conjugation. Upon completion of the reaction, the solution was quenched by adding 0.5 mL of 50 mM EDTA, then transferred to 6–8 kDa dialysis tubing and dialyzed against 4.5 L of 1.0 M NaCl (3  $\times$  8 hours), then 4.5 L of deionized  $\text{H}_2\text{O}$  (6  $\times$  8 hours). The volume in the bag was then transferred to vials, frozen, and lyophilized.

**Analytical Characterization of Click Soluble Antigen Arrays**—NMR spectra were collected on a Bruker Avance AVIII 500 MHz spectrometer equipped with a dual carbon/proton cryoprobe (unless otherwise noted), and all samples were dissolved in 650  $\mu\text{L}$  of  $\text{D}_2\text{O}$  for analysis. MestReNova 11.0 was used for NMR data analysis. The amide methyl resonance ( $\delta \sim 1.90\text{--}2.05$  ppm) of all  ${}^1\text{H}$  NMR spectra was normalized to an integration of 3.0, and the sum of all other signals in the range of  $\delta \sim 1.0\text{--}4.0$  ppm was used to ratiometrically determine the number of azide functionalization sites during HA- $\text{N}_3$  synthesis.

RP-HPLC and SEC analysis were conducted using a Waters Alliance HPLC system equipped with either a diode array detector or dual wavelength UV/Vis detector. For the quantitative determination of peptide conjugation by RP-HPLC, the following equation was used:

$$N_{\text{con}} = \left[ \left( \frac{n_{\text{pep}}}{n_{\text{HA}}} \right) \left( \frac{V_{\text{pre}} - V_{\text{sam}}}{V_{\text{pre}}} \right) \right] \left( 1 - \frac{PA_t}{PA_{\text{start}}} \right) \quad \text{Equation 1}$$

where  $N_{\text{con}}$  = number of conjugated peptides per backbone,  $n_{\text{pep}}$  = moles of peptide used in reaction,  $n_{\text{HA}}$  = moles of HA- $\text{N}_3$  used in reaction,  $V_{\text{pre}}$  = total reaction volume before NaAsc is added,  $V_{\text{sam}}$  = volume of “pre-NaAsc” sample removed from reaction mixture,  $PA_t$  = measured peak area of peptide at time  $t$ ,  $PA_{\text{start}}$  = measured peak area of free peptide before NaAsc is added to the reaction. General chromatographic conditions employed a Waters XBridge  $\text{C}_4$ , 3.5  $\mu\text{m}$ , 300  $\text{\AA}$  stationary phase under ion pairing (0.05% TFA in  $\text{H}_2\text{O}$  and MeCN) mobile phase conditions, utilizing a linear elution gradient (5–70%) with detection at 214 nm.

### Biophysical Characterization

Determination of protein concentrations was done with  $\epsilon_{280 \text{ nm}}$  ( $3 \text{ mL} \cdot \text{g}^{-1} \cdot \text{cm}^{-1}$ ) for human insulin. For derivatized polymers, the concentrations were determined on a total protein basis (the same absorbance) so that the total concentration of insulin is unchanged. Other polymers and fluorescence concentrations were determined by weight.

**Far UV Circular Dichroism**—Far UV circular dichroism spectroscopy was performed using an Applied Photophysics Chirascan equipped with a 6-cell holder (Applied Photophysics, Leatherhead, UK).<sup>33</sup> Proteins were at concentrations of  $\sim 0.1$  mg/ml, in 10 mM phosphate Buffer pH 7.4 or pH 3.0, in a 1-mm quartz cell. CD was measured from 195 – 250 nm and

using a 1 nm step size with a two second integration time at each step. Corresponding buffers were subtracted for each sample.

**Dynamic Light Scattering**—Dynamic light scattering was performed using a DynaPro Plate Reader (Wyatt Technology, Santa Barbara, CA).<sup>34</sup> Incident light was detected in a backscattering configuration and analyzed with an autocorrelator. Twenty  $\mu\text{L}$  of sample, in 10 mM phosphate Buffer pH 7.4, was placed in a clear-bottomed 384 well plate and read at 20°C. Samples were measured 5 times with a 15 second acquisition time. Autocorrelation functions were fit using cumulant analysis and intensity averaged values are reported. Errors are reported as standard deviation of 3 replicates.

**Intrinsic Fluorescence Spectroscopy**—Intrinsic fluorescence was measured as described previously using custom fluorescence plate reader (Fluorescence Innovations, Minneapolis, MN).<sup>34</sup> Briefly, a 285 nm laser was used to excite samples and fluorescence was collected at 180° after passing through a 310 nm longpass filter to block excitation light. A prism dispersed light onto a CCD to quantify the fluorescence as a function of wavelength. 10  $\mu\text{L}$  of sample, in 10 mM phosphate Buffer pH 7.4, was placed in a 384 well plate and covered with 2  $\mu\text{L}$  of silicon oil to prevent sample evaporation. The fluorescence was measured from 10 to 90°C with a step-size of 1.25°C and an equilibration step of 2 min between each temperature. The total intensity from 300 to 400 nm was averaged for each temperature. Error bars represent the standard deviation of 4 replicates.

**Mice**—Female mice, aged 6–8 weeks, were used in all experiments. VH125.NOD mice express, by virtue of knock-in, the variable heavy-chain region from the insulin specific 125 hybridoma, on the NOD background. Together with endogenous light chains, these mice bear ~3 % insulin reactive B cells in the periphery. 125Tg mice express both the heavy- and light-chain from the 125 hybridoma, rendering 100 % of their peripheral B cells reactive to insulin. MD4 mice express both a heavy- and light-chain specific for hen-egg lysozyme (HEL); the sole antigen specificity of all B cells in this mouse. Mice were housed and bred at the University of Colorado Denver Anschutz Medical Campus Vivarium or in the Biological Resource Center at National Jewish Health. All experiments involving mice were performed in accordance with the regulations and with approval of the University of Colorado Denver Institutional Animal Care and Use Committee and National Jewish Health.

**Tissue harvest**—Spleens were harvested in IMDM supplemented with 5 % FCS, 1 mM sodium pyruvate, 50  $\mu\text{g}/\text{mL}$  gentamicin, 100 U/mL pen/strep, 2 mM L-glutamine, and 5E-5 M beta-mercaptoethanol; single cell suspensions were prepared by mechanical disruption. RBC's were lysed with 1mL ACK (150 mM  $\text{NH}_4\text{Cl}$ , 10 mM  $\text{KHCO}_3$ , 100 mM  $\text{Na}_2\text{EDTA}$ ) for 1 min at room temperature (RT). Cells were subsequently washed and resuspended in either complete medium containing 0.1 %  $\text{NaN}_3$  or complete medium alone for staining or calcium measurement, respectively. For staining of VH125.NOD + MD4 B cells, B cells were purified via CD43 negative selection before mixing MD4 B cells (~1%) into the VH125.NOD B cells.

**Flow cytometry**—Cells were resuspended at  $1\text{E}7$  cells/mL in cold complete medium containing 0.1 % sodium azide ( $\text{NaN}_3$ ). 100  $\mu\text{L}$  aliquots containing  $1\text{E}6$  cells were stained

with fluorescently-conjugated monoclonal antibodies. Antibodies against the following cell-surface molecules were used: B220 (RA3–6B2; BD), IgM-AF488 (B76) and, CD79b-PE (fab; HM79). B76 and HM79 were produced in the Cambier laboratory and were directly conjugated to fluorochromes according to the manufacture's protocol. For the detection of B cells expressing insulin reactive B cell receptors, cells were first incubated with or without SAgA<sub>Ins</sub> molecules or hyaluronic acid (HA) alone [0.5 ug] for 20 min at 4 degrees C. After two washes and resuspension in 100 µL medium, cells were stained with monomeric biotinylated insulin (ins-bt) (1:50), and HEL-AF488 (1:200) for VH125.NOD + MD4 experiment, for 20 min at 4°C. Cells were washed again before adding anti-B220 (APC, PE, or BUV396), anti-IgM, fab anti-CD79b and, fab anti-biotin-AF647. Following final incubation and washing, cells were analyzed on a Fortessa X-20 flow cytometer (BD) and analyzed using FlowJo software (Tree Star).

**Calcium mobilization**—For measurements of relative intracellular free calcium concentration ( $[Ca^{2+}]_i$ ), 125Tg RBC-lysed splenocytes (1E7/ mL in complete medium containing 2 % FCS) were incubated with or without SAgA<sub>Ins</sub> or HA, for 4 h at 37°C and 5 % CO<sub>2</sub>. For an additional hour at RT, cells were simultaneously stained with anti-B220-APC (1:500), fab anti-CD79b-PE (1:500) and, loaded with 5 uM Indo-1 acetoxymethyl. After washing once in medium, cells were resuspended at 5E6 cells/ mL in RT medium in 500 µL aliquots. Indo-1 was excited with a 355-nm UV laser, Ca<sup>2+</sup>-bound Indo-1 was detected with a 379/28 bandpass filter; unbound Indo-1 was detected with a 524/40 bandpass filter. Relative free intracellular calcium concentration was determined by calculating the ratio of bound/unbound Indo-1. After acquiring data for 30 s, to establish a baseline, cells were stimulated with the indicated dose of SAgA<sub>Ins</sub> molecules, anti-IgM [B76] and/or ionomycin and data collected for an additional 2 min 30 sec. Relative mean  $[Ca^{2+}]_i$  was measured on a Fortessa X-20 flow cytometer and analyzed with FlowJo software.

**Statistical Analysis**—GraphPad Prism was used to perform statistical analysis including sigmoidal nonlinear regression, ordinary one-way or two-way analysis of variance (ANOVA), and unpaired t-test. ANOVA was followed by Tukey's or Sidak's post-hoc test, where appropriate. The threshold for statistical significance was set to  $p < 0.05$ .

## RESULTS AND DISCUSSION

### Structural Design of Click Soluble Antigen Arrays

SAGAs were synthesized by conjugating multiple modified autoantigen (human insulin alkyne; Ins-alk) molecules to 16 kDa hyaluronic acid (HA) to produce the following conjugates: low valency (2 insulin per HA; <sub>lv</sub>SAgA<sub>Ins</sub>), medium valency (4 insulin per HA; <sub>mv</sub>SAgA<sub>Ins</sub>) and, high valency (9 insulin per HA; <sub>hv</sub>SAgA<sub>Ins</sub>). SAGAs are designed to diffuse from the injection site and drain into secondary lymphoid organs to access B cells and other immune cells. Dintizis' reported antigen structural properties that induce tolerance in B cells and provide a useful design framework: <100 kDa, flexible, and highly soluble. We hypothesized that SAGAs with >5 insulin molecule per HA would induce anergy in insulin-specific B cells (IBCs).

## Synthesis and Analytical Characterization of Click Soluble Antigen Arrays

Both qualitative and quantitative analytical techniques were used to characterize SAgAs and their components. The amine pegylated azide ( $\text{H}_2\text{N-PEG}_3\text{-N}_3$ ) was conjugated to HA via (1-Ethyl-3-(3-dimethylaminopropyl)-carbodiimide)/N-hydroxysuccinimide (EDC/NHS) coupling chemistry.  $^1\text{H}$  NMR was used to quantify azide functionalization of HA-azide revealing an average of 41 azides per HA (Figure 1). This was done by integrating a peak from the HA backbone, highlighted in yellow (Figure 1B;  $\delta(^1\text{H}) \approx 2.0$  ppm), and a peak in HA-azide ( $\text{HA-N}_3$ ) that corresponds to a methylene peak, highlighted in blue (Figure 1A;  $\delta(^1\text{H}) \approx 2.5$  ppm). Resonance peaks  $\delta(^1\text{H}) \approx 2.7$  ppm or 2.9 ppm in Figure 1B correspond to methylene protons in the linker can also be used to determine conjugation efficiency. Due to manual integration performed to determine conjugation and the heterogeneity of HA, this analysis should be considered semiquantitative. Modification of the autoantigen human insulin was conducted by conjugating an alkyne linker (Propargyl-N-hydroxysuccinimidyl ester) via NHS chemistry to furnish insulin-alkyne (Ins-Alk). LC-MS verified the successful synthesis of Ins-Alk and further characterization of the modified protein led to the identification of the site of modification. LC/MS analysis determined that two species of Ins-Alk existed. Either B29 lysine was modified or modification occurred on the N-terminus on the A chain (Figure S1A; S1B), either site being acceptable for retaining accessibility of the bulk of the insulin structure.

CuAAC reaction conditions were used to conjugate Ins-alk to  $\text{HA-N}_3$  to produce prototype low valency  ${}_{\text{lv}}\text{SAgA}_{\text{Ins}}$  (2 Ins per HA). Next, medium valency  ${}_{\text{mv}}\text{SAgA}_{\text{Ins}}$  (4 Ins per HA) and high valency  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  (9 Ins per HA) were analyzed by reverse-phase analytical high-performance liquid chromatography (RP-HPLC) to determine the molecular weight and protein conjugation (Figure S2; See Equation 1). The complete conjugation of Ins-Alk to  $\text{HA-N}_3$  for  ${}_{\text{mv}}\text{SAgA}_{\text{Ins}}$  and  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  can be seen in both Figure S2A and Figure S2B. It should be noted that two aliquots from each reaction were taken before Sodium Ascorbate (NaAsc) was added. One aliquot was used to determine total Ins-Alk in solution and the second was analyzed under the same conditions as the reaction mixture without NaAsc to determine protein degradation over 24h (~1 Ins-Alk).

$^1\text{H}/^{13}\text{C}$  Heteronuclear Single Quantum Coherence (HSQC) NMR spectroscopy was used to qualitatively confirm the homopropargyl linker on the Ins-Alk (green resonance;  $\delta(^1\text{H}) \approx 2.9$  ppm,  $\delta(^{13}\text{C}) \approx 70$  ppm; Figure 2A, 2C). When both human insulin (red resonance) and Ins-Alk (green resonance) HSQC spectra were superimposed, some residue resonance signals pointed towards little to no structural change (Figure 2B, 2D; black square), while distinct conformational differences were predominately seen in the aromatic region for Ins-Alk (Figure 2B; black circles). These differences suggested the installation of the homopropargyl handle caused a buried aromatic amino acid (i.e. phenylalanine) to become solvent exposed, thus becoming detectable by NMR. Finally, HSQC analysis revealed the absence of the unique resonance signal for the homopropargyl linker on Ins-Alk ( $\delta(^1\text{H}) \approx 2.9$  ppm,  $\delta(^{13}\text{C}) \approx 70$  ppm; black triangle) in both the  ${}_{\text{mv}}\text{SAgA}_{\text{Ins}}$  and  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  spectrum (Figure 2E and 2F), thus confirming the final products contained only the conjugated protein.

Circular Dichroism (CD) analysis of human insulin was consistent with previously reported alpha helical secondary structure (Figure 3A, 3B).  $\text{SAgA}_{\text{Ins}}$  mostly retained alpha helical

secondary structure in both neutral (pH 7.4) and acid media (pH 3.0), however,  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  appeared to lose significant secondary structure under acidic conditions (Figure 3A, 3B). Further analysis of CD data revealed greater loss of alpha helical structure for  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  when compared to  ${}_{\text{mv}}\text{SAgA}_{\text{Ins}}$  in both acidic and neutral solutions (Figure 3A, 3B). When directly studying the effect of pH on each SAgAs, secondary structure was compromised at lower pH when compared to neutral conditions. HSQC NMR analysis in combination with CD data may explain the loss of secondary structure of SAgA<sub>Ins</sub> when compared to native human insulin. Alkyne modification resulted in a physical change in protein structure that permitted hydrophobic residues to be detected using HSQC NMR. These hydrophobic residues such as tyrosine may interfere with an alpha helical structure. In addition, acidic amino acids (i.e. aspartic acid and glutamic acid) become more protonated at lower pH, which may disrupt salt bridges which could alter the peptide secondary structure.

Melting of the secondary structure as monitored by CD (Figure 3C) shows a minor transition in the insulin secondary structure ( $T_m \sim 55^\circ\text{C}$ ) which is substantially reduced when the protein is conjugated to HA. A temperature melt plot based on intrinsic fluorescence (Figure 3D) showed only weak evidence of the transition for insulin alone with the modified forms manifesting its absence. This may be explained by the fact that insulin contains three disulfide bonds which strongly stabilize the protein. The loss of the transition in the conjugated form suggests some further stabilization of the protein. Finally, dynamic light scattering showed a significant size increase for the conjugated forms (Table 1). A large increase in size for  ${}_{\text{hv}}\text{SAgA}_{\text{Ins}}$  may correlate with the partial loss in alpha helical structure (Figure 3), where the SAgA<sub>Ins</sub> would now favor more extended forms as well as intermolecular interactions that may lead to self-association.

### ***SAgA<sub>Ins</sub> binding and effects on ex vivo IBCs***

**Insulin-SAgAs bind specifically to insulin reactive B cells**—To assess the immunological effects of multimeric, insulin-polymer (SAgA<sub>Ins</sub>) molecules, we first determined if SAgA<sub>Ins</sub> are capable of ligating B cell receptors (BCR) on the surface of IBCs. To this end, we utilized B cells from 125Tg mice in which, by virtue of heavy- and light-chain knock-in, harbor peripheral B cells with an insulin reactivity-fixed receptor repertoire. Red blood cell (RBC)-lysed, 125Tg splenocytes were first incubated with or without SAgA<sub>Ins</sub> (low or high avidity) or hyaluronic acid (HA) alone for 20 min, at 4 °C, in complete medium containing 0.1 % NaN<sub>3</sub>. Staining under these conditions prevents the internalization of ligated BCR. After being washed, cells were exposed to monomeric biotinylated insulin (ins-bt), washed, and subsequently stained with antibodies against B220 (B cells), CD79b (BCR) and, immunoglobulin (IgM, BCR) together with anti-biotin. Depicted in Figure 4A, pre-treatment with SAgA<sub>Ins</sub>, but not HA alone, blocked binding of ins-bt. Staining in which ins-bt was omitted served as a positive control and staining with no SAgA<sub>Ins</sub> pre-treatment served as a negative control. In addition, neither SAgA<sub>Ins</sub> nor ins-bt bound to non- (B220-) B cells (data not shown). In anticipation of experiments in which we re-stimulate SAgA<sub>Ins</sub> tolerized IBCs, we wanted to ensure that SAgA<sub>Ins</sub> binding to the BCR did not obscure binding of BCR stimulating antibodies. In this case, cells previously exposed to the SAgA<sub>Ins</sub> were subsequently stained with anti-IgM [B76] and anti-CD79b [HM79]. No change in staining intensity was detected for anti-BCR antibodies in cells

pretreated with SAgA<sub>Ins</sub> (Figure 4B). Finally, to address SAgA<sub>Ins</sub> binding in a more physiologic, clonally diverse setting, we utilized B cells (CD43-) purified from spleens of VH125.NOD mice in which ~1–3% of peripheral B cells bind insulin. To ensure specificity, MD4 B cells (HEL reactive) were mixed in at approximately the same frequency as IBCs. As before, cells were pretreated with SAgA<sub>Ins</sub> or HA alone before being stained with ins-bt/fab anti-bt-AF647 and HEL-AF488. As displayed in Figure 4C, SAgA<sub>Ins</sub> blocked binding of ins-bt but not HEL-AF488.

**In vitro incubation of IBCs with insulin-SAgA leads to decreased expression of BCR and desensitization of the BCR to additional stimulation**—SAgA<sub>Ins</sub> are designed as potential therapeutic agents for preventing the development of T1D. B cells are required for the development of T1D in mice and have been strongly implicated in human disease, probably functioning as antigen presenting cells needed for T cell activation in the pancreas.<sup>35</sup> Depletion of B cells with an anti-CD20 antibody (rituximab) has been shown to delay the progression of disease in humans.<sup>36</sup> Similarly, tolerization of peripheral B cells by chronic BCR stimulation has been observed to delay disease onset in mice.<sup>37</sup> Following from this, we hypothesized that tolerizing antigen-(insulin) specific B cells may prove to be similarly efficacious in preventing T1D progression. Antigen specific tolerization comes with the added benefit of allowing the remainder of the B cell compartment to remain active for fighting infection and responding to vaccination.

To determine if SAgA<sub>Ins</sub> are capable of tolerizing IBCs, we again utilized B cells from the 125Tg mouse. We first measured intracellular calcium mobilization in response to acute stimulation with SAgA<sub>Ins</sub> (Figure 5A). Anti-IgM and HA alone were used as positive and negative controls, respectively. SAgA<sub>Ins</sub> stimulated a similar calcium flux in comparison to stimulation with anti-IgM (note that 125Tg B cells exclusively express IgM). Next, we incubated 125Tg IBCs with or without SAgA<sub>Ins</sub> or HA alone for ~5 h before measuring surface BCR expression and calcium mobilization (Figure 5B, 5C). Pre-incubation with SAgA<sub>Ins</sub> led to decreased expression of surface BCR, as measured by CD79b, reminiscent of chronically stimulated, anergic B cells found in mice and humans (Figure 5B).<sup>35</sup> Pre-incubation with SAgA<sub>Ins</sub>, but not HA, rendered IBC's refractory to re-stimulation through the BCR (Figure 5C). This inhibition was not due to masking of the epitope on the BCR recognized by B76 (Figure 5B) and was independent of the SAgA<sub>Ins</sub> induced decrease in surface BCR (gating in Figure 5B). In addition, cells incubated with SAgA<sub>Ins</sub> remained refractory to a 5-fold excess of anti-IgM stimulation (Figure 5C dashed lines), which as expected increased calcium response in untreated or HA treated cells (Figure 5A, 5C). Finally, SAgA<sub>Ins</sub> induced desensitization of the BCR is independent of Inositol trisphosphate receptor (IP3) receptor-mediated release of intercellular calcium stores, since stimulation with the calcium ionophore, ionomycin, resulted in similar calcium influx in SAgA<sub>Ins</sub> treated, HA treated, and untreated cells. This suggests that SAgA<sub>Ins</sub>-induced tolerance of IBCs may rely on mechanisms observed to be operative in anergic B cells found in mice and humans.<sup>38</sup>

## CONCLUSIONS

SAGAs were successfully synthesized by conjugating multiple modified autoantigen human insulin (Ins-alk) molecules to the 16 kDa linear polymer hyaluronic acid (HA) to produce the following conjugates: low valency  $_{lv}$ SAG $_{Ins}$  (2 insulin per HA), medium valency  $_{mv}$ SAG $_{Ins}$  (4 insulin per HA) and, high valency  $_{hv}$ SAG $_{Ins}$  (9 insulin per HA). Insulin conjugated to SAG $_{Ins}$  maintained alpha helical structure at physiological pH. Different valency SAG $_{Ins}$  did not appear to modulate biologic activity, producing similar levels of receptor blockade and BCR desensitization. SAG $_{Ins}$  bound specifically to IBCs without blocking epitopes recognized by antibodies against the BCR. The inability of SAG $_{Ins}$ -treated IBCs to respond to BCR stimulation could potentially be explained simply by blocking of BCR epitopes recognized by the stimulating antibodies. Thus, the mechanism was more deeply assessed. Pre-incubation of IBCs (125Tg) with SAG $_{Ins}$ , but not HA, rendered the BCR desensitized to re-stimulation. This effect was independent of SAG $_{Ins}$  induced decrease in BCR expression and was also independent of IP3R-mediated intracellular calcium release. Activity was dependent on SAG $_{Ins}$  binding to BCR on the surface of IBCs and its ability to acutely stimulate these cells. SAG $_{Ins}$  silenced IBCs by inducing refractory B cell receptor signaling resulting in a mechanism of immune tolerance similar to B cell anergy, thus mimicking a known mechanism of peripheral tolerance.

**Figure 1:**  
<sup>1</sup>H NMR spectra of hyaluronic acid (HA) and hyaluronic acid azide (HA-N<sub>3</sub>). Peaks used to determine the average number of azides in HA-N<sub>3</sub> are highlighted in yellow and blue.

**Figure 2:** Overlapped HSQC NMR spectra of insulin (red resonance) and insulin alkyne (green resonance) (A-D). Multivalent SAgAs ( $_{mv}SAgA_{Ins}$ ) E and ( $_{hv}SAgA_{Ins}$ ) F show no resonances from the alkyne peak found only Ins-Alk present in either of the final compounds. The alkyne peak found in Ins-Alk is not found in any of the products, which implies no residual unconjugated insulin. HSQC NMR of A uses a black triangle to highlight the terminal alkyne proton in Ins-Alk. B shows more available aromatic residues in Ins-alk (green) when compared to insulin. C and D highlight similarities (black squares) and

differences (black circles) between insulin alkyne (green resonance) and insulin (red resonance).

**Figure 4:** Specific binding of  $SAGAI_{Ins}$  to insulin binding cells (IBCs). Both low-avidity ( $ivSAGAI_{Ins}$ ) and high-avidity ( $hvSAGAI_{Ins}$ ) molecules, but not hyaluronic acid (HA) alone, block binding of monomeric biotinylated-insulin to insulin-specific (B220+;125Tg) B cells (A.). Pretreatment of 125Tg B cells with either  $SAGAI_{Ins}$  or hyaluronic acid does not block epitopes recognized by anti-IgM [B76] nor anti-CD79b [HM79] (B.).  $SAGAI_{Ins}$  molecules block binding of insulin-bt to insulin specific B cells (CD43-, B220+;VH125.NOD) but not binding of hen egg lysozyme (HEL) to HEL specific B cells (CD43-, B220+;MD4) when both cell types are present at similar frequencies (C.). Layout gate frequencies represent percent of B cells (B220+). Data are representative of at least 3 independent experiments.

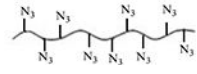

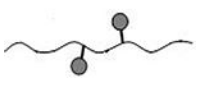

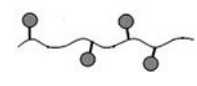

**Figure 5:** SAgA<sub>Ins</sub> effects on ex-vivo, insulin-binding cells (IBCs). SAgA<sub>Ins</sub> molecules, but not hyaluronic acid (HA) alone, are capable of aggregating B cell receptors (BCR) on insulin specific B cells (125Tg) and stimulating extracellular calcium influx (A.). 5 hour pre-incubation of IBCs (125Tg) with SAgA<sub>Ins</sub>, but not HA, leads to decreased expression of BCR on the surface of IBCs (B.). Pre-incubation with SAgA<sub>Ins</sub> renders IBCs refractory to re-stimulation through the BCR by anti-IgM [B76] but not to stimulation with the calcium ionophore, ionomycin (io) (C.). This induced tolerance is independent of the surface expression of BCR (gating in B.). Dashed calcium traces represent AgA<sub>Ins</sub> treated (C.) or untreated (A.) cells stimulated with a 5-fold excess [25 ug] of anti-IgM. Data are representative of at least 3 independent experiments.
