24

25

26   Osteoarthritis (OA) is the most prevalent musculoskeletal disease and a leading

27   cause of disability worldwide. OA mostly affects the population aged over 50

28   years and it is estimated that the population with OA will double in the next 30

29   years. The pathogenesis of OA is a complex process that involves the entire

30   joint. The pathological cascade of events in OA occur at the molecular, cellular

31   and tissue level and not only involve cartilage degradation but also sub-

32   chondral sclerosis, synovial inflammation as well as damage to other joint

33   structures such as ligaments and menisci, causing pain and loss of articular

34   function (1). Although the cartilage degradation is not the only event responsible

35   for joint degradation its role in OA pathogenesis continuous to be relevant. One

36   factor that contributes to the pathological cascades is the imbalance between

37   apoptosis and autophagy in the articular cartilage (1).

38

39   Mitochondria are currently in the focus of biomedical research due to

40   their role in aging and in the development of human pathologies (2).

41   Mitochondria are the organelles that convert the nutritional molecules into

42   adenosine triphosphate (ATP), generating most of the energy necessary for the

43   cell. Mitochondrial dysfunction causes a series of metabolic alterations that lead

44   to an increase in the production of reactive oxygen species (ROS) and

45   decreasing ATP and oxygen consumption. Mitochondrial dysfunction causes

46   also an inflammatory response inducing synthesis of cytokines and MMPs.

47   Mitochondria contain their own genetic material, mtDNA; mtDNA has a high

48   mutation rate, due to the absence of an effective system of repair and its

49   proximity to the main source of ROS production in the cell, the electron

50   transport chain.

51

52   Increasing evidence suggests that mitochondria are involved in the

53   pathogenesis of OA (3). Analyses of mitochondrial function in OA chondrocytes

54   reveal decreased activity of the mitochondrial respiratory complexes II and III as

55   well as increased mitochondrial mass, compared to healthy chondrocytes.

56   Mitochondrial dysfunction can contribute to cartilage degeneration in OA.

57   Increased ROS production, impaired anabolic and growth responses of

58 chondrocytes, excessive and reduced chondrocyte apoptosis and autophagy

59 respectively, and enhanced inflammatory responses are particularly important.

60 Compared to normal cartilage, OA chondrocytes fail to generate energy and

61 mitochondrial biogenesis is altered. All the data suggest that mitochondria and

62 mitochondrial function needs to be regulated in order to prevent the generation

63 of high levels of ROS and oxidative stress.

64

65   Autophagy, which is activated under hypoxic and energy stress to

66 provide energy for the cell, is a key regulator of cellular homeostasis through

67 the removal of damaged macromolecules and organelles, including

68 mitochondria (4). Mitophagy is the elimination of depolarized/damaged

69 mitochondria. Pharmacological activation of autophagy in chondrocytes

70 significantly protected against mitochondrial dysfunction suggesting that

71 mitophagy may function to eliminate damage/dysfunctional mitochondria in

72 chondrocytes and prevent oxidative stress (4). Studies in human chondrocytes

73 showed that activation of autophagy is critical in protecting against

74 mitochondrial dysfunction (5). Moreover, the mammalian target of rapamycin

75 inhibitor DNA damage-inducible transcript 4 protein (DDIT4, also known as

76 REDD1) is a key mediator of cartilage homeostasis through the regulation of

77 autophagy and mitochondrial biogenesis; expression of DDIT4 is decreased in

78 OA cartilage, and deficiency of this protein exacerbates the severity of injury-

79 induced OA (6).

80

81   In this issue of Osteoarthritis and Cartilage, Ansari MY et al. suggest that

82 Parkin-mediated mitophagy is an important mechanism to limit ROS production

83 and improve OA chondrocyte survival under pathological conditions (7). Parkin

84 is an E3 ubiquitin ligase; it is selectively recruited to dysfunctional mitochondria

85 with low membrane potential. After recruitment, Parkin mediates the engulfment

86 of mitochondria by autophagosomes and the selective elimination of impaired

87 mitochondria. Authors propose that increased expression of Parkin might be

88 involved in the clearance of damaged mitochondria and indeed OA

89 chondrocytes with depleted Parkin expression showed increased production of

90 ROS, accumulation of dysfunctional mitochondria, and apoptosis. These

91 authors speculate that loss of Parkin function could contribute directly to the

92   pathogenesis of OA.

93

94   The interaction between Parkin and mitochondrial NAD-dependent
95   protein deacetylase sirtuin 3 (SIRT-3) is a very interesting aspect to understand
96   the relevance of the results reported by Ansary MY et al. SIRT-3, the chief
97   deacetylase mitochondrial protein, has been shown to mediate age-related
98   changes in cartilage redox regulation; this action protected against early-stage
99   OA in rats and SIRT-3 has been described as a metabolic sensor that responds
100   to changes in the energetic state of the cell through oxidized nicotinamide
101   adenine dinucleotide, to regulate mitochondrial acetylation and protect against
102   mitochondrial damage. SIRT-3 activates mitophagy and its deficiency impairs
103   mitophagy by increasing acetylation of Pink/Parkin and decreasing Parkin
104   expression (8) (Figure 1).

105

106   Mitochondrial dysfunction has also been associated with a disbalance
107   between ROS production and expression of superoxide dismutase 2 (SOD2),
108   the major mitochondrial antioxidant protein. Downregulation of SOD2 has been
109   reported in OA chondrocytes (9). Levels of this enzyme are decreased in the
110   superficial layer of OA cartilage and markedly down-regulated in end-stage OA
111   cartilage. Both SOD2 and SIRT-3 activity decreased with age in cartilage and
112   treatment with SIRT-3 increased SOD2 activity suggesting that SIRT-3 could
113   mediate age-related changes in cartilage redox regulation and protect against
114   OA by rescuing acetylation-dependent inhibition of SOD2 activity (10).

115

116   The proposed theory for the participation of mitochondria in OA suggests
117   that dysfunction of the mitochondrial respiratory complex leads to increased
118   production of ROS, resulting in mtDNA damage followed by mutations that
119   compromise mitochondrial protein function and further increase production of
120   ROS and reactive nitrogen species (RNS). mtDNA shows very high mutation
121   and sequence evolution rates. The accumulated mtDNA mutations throughout
122   evolution persist today as high frequency continent-specific mtDNA
123   polymorphisms and are called haplogroups (11, 12). Specific mtDNA
124   haplogroups have been consistently linked with a wide spectrum of diseases,
125   including OA. Evidence has accumulated from a series of studies for an

126 association between mtDNA haplogroups and prevalence, incidence and
127 progression of OA in different cohorts of patients (13, 14). In terms of a direct
128 relationship between mtDNA damage and haplogroups, greater damage could
129 be expected in those haplogroups associated with increased ROS production.
130 mtDNA haplogroups H and J have been found to differ in the gene expression
131 and activity of SIRT-3 under simulated mild oxidative stress conditions using
132 transmitochondrial cybrids, where H cybrids showed higher SIRT-3 activity and
133 expression than J cybrids (15). These data suggest that mtDNA mutations and
134 variants could modulate mitophagy through their capacity to regulate different
135 nuclear target genes such as SIRT-3 and NAD-dependent protein deacetylase
136 sirtuin-1 (SIRT1). SIRT1 is involved in mitochondria biogenesis inducing the
137 expression of –peroxisome proliferator-activated receptor γ co-activator 1α
138 (PGC-1α; the so-called master regulator of mitochondrial biogenesis) (16).
139
140   A decreased capacity for mitochondrial biogenesis in chondrocytes is
141 linked to reduced AMP-activated protein kinase (AMPK) activity and decreased
142 expression of SIRT1, PGC1α; TFAM (transcription factor A, mitochondrial),
143 nuclear respiratory factor 1 (NRF1) and NRF2 (16). AMPK is a key molecule
144 associated with metabolism in chondrocytes that regulates energy metabolism
145 through the downstream mediators such as SIRT1 and mechanistic target of
146 rapamycin (mTOR) (17). Activation of the AMPK–SIRT1–PGC1α pathway
147 increases mitochondrial biogenesis in chondrocytes, limiting OA progression.
148 Furthermore, deficiency in AMPK and SIRT1 modulates PGC1α activity, leading
149 to reduced oxidative stress and procatabolic responses in chondrocytes from
150 patients with OA (16).
151
152   All these results open a wide new spectrum of therapeutic approaches
153 with the common goal of restoring mitochondrial function in chondrocytes and
154 reducing the mitochondrial stress. Some new potential therapies could be: 1) To
155 activate the AMPK-SIRT-3 pathway in order to induce Parkin expression and
156 mitophagy 2) To activate the AMPK-SIRT-3 pathway in order to induce SOD2
157 activity a reducing Mitochondrial stress. 3) Activation of the AMPK–SIRT1–
158 PGC1α pathway to promote mitochondrial biogenesis, 4) The development of

159 cellular therapy using cells with harboring "good mitochondria", or even the
160 administration of isolated "good mitochondria" into the osteoarthritic joint.
161
162   In summary, the study of Ansary MY et al. is in line with other published
163 results that confirm the relevant role of mitochondrial activity and function in the
164 process of articular cartilage degradation and in the pathogenesis of OA. In
165 particular, some molecules such as AMPK, Parkin, SIRT-1, SIRT-3 and PGC1-
166 alpha may represent therapeutic targets for modulating mitophagy and
167 mitochondrial biogenesis, which may represent new therapeutic alternatives in
168 OA. It is necessary to confirm these promising results using in vivo models.
