#### Abstract

Nineteen new phenanthrene-based tylophorine analogs with various functional groups on the piperidine moiety were designed, synthesized and evaluated for in vitro anticancer activity against four human tumor cell lines. Analogs $\mathbf{1 5}$ and $\mathbf{2 1}$ showed approximately two-fold enhanced inhibitory activity as compared with our prior lead compound (PBT-1). Analogs 23 and 24 with $S$ - and $R$ configured substituents, respectively, at the piperidine 3 '-position exhibited comparable cytotoxicity to that of PBT-1. Furthermore, mechanistic studies to investigate the effects of the new compounds on Akt protein in lung cancer cells and the NF-kB signaling pathway suggested that the compounds may exert their inhibitory activity on tumor cells through inhibition of activation of both Akt and NF-kB signaling pathway.

## Introduction

Phenanthroindolizidine and phenanthroquinolizidine alkaloids comprise a class of pentacyclic natural products isolated primarily from Cynanchum, Pergularia, and Tylophora species in the Asclepiadaceae family. ${ }^{1,2}$ Many of these alkaloids show strong bioactive effects against human diseases, such as cancers. For example, antofine and tylophorine (Figure 1) showed potent cytotoxic effects in antitumor screening launched by the National Cancer Institute, which has aroused great interest in exploring the synthesis and biological activities of these compounds and their derivatives. The main goal of such efforts was to obtain drug candidates with higher inhibitory potency and lower side effects, especially reduced or no central nervous system (CNS) toxicity, which is associated with the natural tylophorines. ${ }^{3}$ Although the biochemical targets of tylophorine and related bioactive principles are still unknown, recent research has indicated that the NF- $\kappa$ B signaling pathway and the synthesis of a number of cell cycle proteins, such as cyclin $\mathrm{D}_{1}$, are suppressed during treatment with these alkaloids. ${ }^{4,5,10}$

[^0]In our previous research, we reported the synthesis and cytotoxic activity of a series of structurally simplified phenanthrene-based tylophorine (PBT) analogs, as well as structureactivity relationship conclusions. We investigated various structural building blocks, including amino acid derivatives, pyrrolidine derivatives (substituted at C-2'), piperidines (substituted at C-2' and C-4'), and piperazine derivatives, which are connected to the core tricyclic phenanthrene structure through a methylene bridge. PBT-1, which has a 4'-hydroxymethyl piperidine moiety (Figure 1), was the most active among these compounds against four types of human cancer cell lines, including multi-drug resistant (MDR) KB-VIN cells, with low $\mathrm{IC}_{50}$ values around $80 \mathrm{nM} .{ }^{6,7}$.

The promising results obtained with a diverse but limited series of target compounds have prompted us to further explore the pharmacophores of natural tylophora alkaloids, such as antofine. Our goals are to develop new potential drug candidates, as well as to study the mechanism of action and identify the molecular target(s) of the new compounds. Based on the SAR information obtained in our previous work, we have synthesized new PBT-1 analogs with different substituents at the C-3' and C-4' positions of the piperidine ring. Substituents containing amino or hydroxy groups were introduced to increase the water solubility and polarity of the compounds, while retaining their ability to form hydrogen bonds with the putative binding target. Because a longer side chain in the piperidine ring led to a significant reduction in efficacy, ${ }^{7}$ we chose functional groups similar in size to the hydroxymethyl group of PBT-1. Functional groups such as methyl ester, cyano, trifluoromethyl, and methylsulfonylamino groups were also introduced at the C-3' or C-4' position to obtain information useful in assisting further drug structure design and optimization.

We have recently reported that PBT-1 can induce cell cycle G2/M arrest and apoptosis by suppressing Akt and NF-kB signaling pathways. ${ }^{10}$ Therefore, we were also interested in determining whether the new cytotoxic compounds synthesized in our current study share the same mechanism as PBT-1. To answer this question, a series of active new compounds were selected for further mechanistic studies.

Tylophora natural products with a pentacyclic structural scaffold have long been known as potent antitumor agents, with activity against a variety of tumor cell lines. PBT derivatives are considered to be analogs of natural or synthetic tylophora products. They share the tricyclic phenanthrene core structure, but have only one rather than two methylene linkages to a fourth, rather than fifth, pyrrolidine or piperidine D ring. In our previous study, certain PBT analogs, along with the tylophora natural products, were investigated in mechanism of action studies. The results showed that although the two compound series are structural analogs, they are not biologically functional analogs, because they do not share the same spectrum of molecular targets. ${ }^{11}$ This finding encouraged us to further study the optimal conformations of the natural products and PBT analogs and to learn whether minor structural variations affect their binding conformation and interaction with the target(s).

In this article, we report our recent research results in the synthesis, biological evaluation, preliminary mechanistic study results, and structural conformational analysis of the most potent new compound 21, in comparison with the natural product antofine.

## Results and Discussions

The general synthetic methods used to prepare target derivatives are shown in Scheme 1. The phenanthrene-9-carboxylic acid 3, obtained via three steps as reported in the literature, ${ }^{6}$ was reacted with methyl iodide using sodium bicarbonate to afford the methyl ester $\mathbf{4}$, which was then reduced with $\mathrm{LiAlH}_{4}$ at room temperature to give the alcohol $\mathbf{5}$, followed by bromination using tribromophosphine in dichloromethane. ${ }^{8}$ For the final step, the bromine atom of $\mathbf{6}$ was
displaced by various substituted piperidines at room temperature or $60^{\circ} \mathrm{C}$ to afford target products. The Boc group was removed with HCl in MeOH and sulphonylamination was carried out in $\mathrm{CH}_{2} \mathrm{Cl}_{2} .{ }^{9}$ The ketone moiety was reduced with $\mathrm{LiAlH}_{4}$ to form the corresponding alcohol in excellent yields.

Totally, 19 compounds were synthesized (two were R/S mixtures) and screened for in vitro anticancer activity against a panel of human tumor cell lines including KB (nasopharyngeal), A549 (lung), DU-145 (prostate), and KB-VIN (an MDR KB subline). The screening results are shown in Table 1.

Most compounds exhibited significant activity, with 15 and 21 showing the highest potency with $\mathrm{IC}_{50}$ values in the $0.08-0.14 \mu \mathrm{M}$ range. Changing the position of the hydroxymethyl substituent from C-4' in PBT-1 to C-3' in 23 and $\mathbf{2 4}$ did not affect the potency; all three compounds had similar $\mathrm{IC}_{50}$ values. The stereochemistry of the side chain in the latter two compounds also had little effect on potency. However, compound 21 was ca. twofold more active compared with PBT-1, as indicated by lower $\mathrm{IC}_{50}$ values ( $0.08-0.11$ compared with $0.18-0.24 \mu \mathrm{M})$. Because 21 has a 4'-hydroxyl rather than 4'-hydroxymethyl substituent on the piperidine ring, the augmented efficacy might be explained by a better fit into the binding pocket and better interaction with the target groups, possibly through hydrogen bonding with the oxygen atom at the $\mathrm{C}-4$ ' position (directly or indirectly).

Interestingly, compound $\mathbf{1 5}$, the oxidized form of 21, possessed similar, high potency, indicating that the oxygen atom could be used primarily as a hydrogen bond acceptor, as long as the spatial distance is favorable, while a possible covalent adduct (to the ketone) is less likely to be formed. However, when the oxo group was at the C-3' rather than $\mathrm{C}-\mathbf{4}^{\prime}$ position ( $\mathbf{2 2}$ vs. 15), the inhibitory potency decreased by about eightfold, possibly indicating less optimal hydrogen bonding with the target in the binding pocket. Potency decreased even more when a methyl ester was present at $\mathrm{C}-3^{\prime}$ in addition to an oxo group at $\mathrm{C}-4^{\prime}$ (compare 16 and 15). In fact, compound $\mathbf{1 6}$ showed the same potency as $\mathbf{1 8}$ and $\mathbf{1 9}$, which have only a methyl ester (cis and trans, respectively) at C-3'. Thus, the oxygen atom at C-4' in $\mathbf{1 6}$ might be displaced from its optimal hydrogen bonding angle as in $\mathbf{1 5}$, and thus, the oxo group might not be involved in binding.

A lipophilic trifluoromethyl group at C-4' (13) substantially decreased the inhibitory activity. Compound 14 with a cyano moiety at the same position showed significant activity, but was five- to ten-fold less potent compared with compounds containing an oxo (15), hydroxy (21), or hydroxymethyl (PBT-1) group, which might be associated with the oxidation state of nitrogen and particular orientation of its lone pair of electrons.

With $\mathrm{IC}_{50}$ values ranging from 0.26 to $0.49 \mu \mathrm{M}, \mathbf{2 0}\left(4^{\prime}-\mathrm{CH}_{2} \mathrm{NH}_{2} . \mathrm{HCl}\right)$ showed the greatest potency among the amino compounds. Compounds with the amino group present as the HCl salt showed uniformly better activity compared with their Boc-protected precursors, perhaps resulting from elevated water solubility and side chain shortening after removal of Boc. However, the amine salts generally were less active than the corresponding compounds with a hydroxy group (PBT-1 vs. 20, 21 vs. 12, 24/25 vs. 7), suggesting that formation of a hydrogen bond alone cannot explain all interactions between these compounds and their targets. Compounds $7\left(3^{\prime}-\mathrm{CH}_{2} \mathrm{NH}_{2}\right)$ and $8\left(3^{\prime}-\mathrm{CH}_{2} \mathrm{NHBoc}\right)$ showed significantly higher inhibition than $9\left(3^{\prime}-\mathrm{NH}_{2}\right)$ and $\mathbf{1 0}$ (3'-NHBoc), respectively. The extra methylene could put the hydrogen bond acceptor closer to hydrogen bond donor in the binding pocket. Comparison of $\mathbf{1 1}$ ( $4{ }^{\prime}$-NH-Boc or $\left.4^{\prime}-\mathrm{NHCO}_{2} t-\mathrm{Bu}\right)$ and $\mathbf{1 7}\left(4^{\prime}-\mathrm{NHSO}_{2} \mathrm{CH}_{3}\right)$ with $\mathbf{1 2}\left(4^{\prime}-\mathrm{NH}_{2} . \mathrm{HCl}\right)$ showed only moderate decreases in potency with the former two compounds, indicating that substitutions at C4'$\mathrm{NH}_{2}$ group do not significantly affect activity.

The 19 newly synthesized compounds were also examined for their effects on Akt (Figure 2) and the NF- $\kappa$ B signaling pathway (Figure 3) in A549 and CL1-0 cells. ${ }^{10}$ Four compounds, 15 (YXM35), 21 (YXM41), 23 (YXM43), and 24 (YXM44), which were more active than or comparable to PBT-1 against the tested tumor cell lines, consistently showed more potent suppression of Akt activation than PBT-1 in both lung cancer cells, especially in decreasing Akt protein phosphorylation. Further assays are still needed to distinguish whether the inhibitory activity on Akt is due to transcriptional inhibition or protein stability.

In addition, when evaluated for effects on the NF- $\kappa B$ signaling pathway, the four compounds also showed more potent suppression of NF-кB activity than PBT-1, parallel to the results in our cell-based cytotoxicity testing, suggesting that these compounds may inhibit tumor cell growth through inhibition of both Akt activation and NF-кB related signaling pathway.

The conformations of 21 and antofine were energy-minimized and superimposed, and the results are shown in Figure 4. It was obvious that the side-chain orientation of 21, the PBTanalog, was distinct from the remainder of the natural product antofine. Thus, the conformational variation between antofine and our PBT analogs may affect the binding affinity in the binding site(s) and further affect the interaction between drugs and target molecule(s).

## Conclusions

Nineteen novel PBT-based analogs with different substituents on the C-3' and C-4' positions of the piperidine ring were designed and synthesized. Among them, four compounds 15, 21, 23, and 24 showed comparable activity and were more potent than the remaining compounds against four tumor cells. Preliminary mechanism studies indicated that, although these new compounds are analogs of PBT-1, they might not share the same mechanism to fully interact with the target molecule(s). The inhibitory activity of the new compounds against tumor cell growth may be induced by inhibition of the activation of Akt and NF- $\kappa$ B signaling pathway in tumor cells. Conformation analysis indicated that the PBT analogs possess a different sidechain orientation from that of the natural product antofine. Further studies are warranted to confirm the biological effects of the compounds. In summary, $\mathbf{1 5}$ and $\mathbf{2 1}$ were identified as new more active PBT derivatives and are the basis for our ongoing ligand-based design efforts.

## Experimental Section

Melting points were measured using a Fisher Johns melting apparatus without correction. Proton nuclear magnetic resonance ( ${ }^{1} \mathrm{H}$ NMR) spectra were measured on a 300 MHz Gemini spectrometer using TMS as internal standard. The solvent used was $\mathrm{CDC}_{13}$ unless indicated. Mass spectra were recorded on a Shimazu-2010 LC/MS/MS instrument equipped with a Turbo IonsSpray ion source.

## 2,3-Methylenedioxy-6-methoxyphenanthrene-9-carboxylic Acid Methyl Ester (4)

The carboxylic acid $(1.16 \mathrm{~g}, 3.92 \mathrm{mmol})$ was suspended in 30 mL of DMF, to which $\mathrm{NaHCO}_{3}(527 \mathrm{mg}, 6.27 \mathrm{mmol})$ and $\mathrm{CH}_{3} \mathrm{I}(0.49 \mathrm{~mL}, 7.80 \mathrm{mmol})$ were added. The mixture was stirred overnight at room temperature before 20 mL water was added to quench the reaction. EtOAc was used for extraction. The organic layers were collected and washed with water and brine, dried over $\mathrm{MgSO}_{4}$. The methyl ester was found to be clean enough for the next step without further purification (quantitative). ${ }^{1} \mathrm{H} \mathrm{NMR}\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 8.27$ (d, $J=9.30$ $\mathrm{Hz}, 1 \mathrm{H}), 7.90(\mathrm{~s}, 1 \mathrm{H}), 7.81(\mathrm{~d}, J=2.40 \mathrm{~Hz}, 1 \mathrm{H}), 7.40(\mathrm{~s}, 1 \mathrm{H}), 7.22(\mathrm{dd}, J=9.00 \mathrm{~Hz}, J=2.40$ $\mathrm{Hz}, 1 \mathrm{H}), 7.16(\mathrm{~s}, 1 \mathrm{H}), 6.10(\mathrm{~s}, 2 \mathrm{H}), 4.00(\mathrm{~s}, 3 \mathrm{H}), 3.90(\mathrm{~s}, 3 \mathrm{H})$; ESI MS m/z $310.95(\mathrm{M}+\mathrm{H})^{+}$.

## 2,3-Methylenedioxy-6-methoxy-9-hydroxylmethyl-phenanthrene (5)

The ester ( $500 \mathrm{mg}, 1.61 \mathrm{mmol}$ ) in 30 mL THF was added to $\mathrm{LiAlH}_{4}$ in 20 mL THF in an ice bath, which was then stirred at room temperature for 2 h . Five mL of water and 5 mL of 2 N NaOH were added and the mixture was filtered. The solvent was removed under vacuum and redissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, which was washed with brine and dried over $\mathrm{MgSO}_{4}$. The product was used without further purification. ${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 8.26(\mathrm{~d}, J=9.30 \mathrm{~Hz}, 1 \mathrm{H})$, $7.88(\mathrm{~s}, 1 \mathrm{H}), 7.81(\mathrm{~d}, J=2.40 \mathrm{~Hz}, 1 \mathrm{H}), 7.40(\mathrm{~s}, 1 \mathrm{H}), 7.23(\mathrm{dd}, J=9.00 \mathrm{~Hz}, J=2.40 \mathrm{~Hz}, 1 \mathrm{H})$, $7.15(\mathrm{~s}, 1 \mathrm{H}), 6.09(\mathrm{~s}, 2 \mathrm{H}), 4.96(\mathrm{~s}, 2 \mathrm{H}), 4.01(\mathrm{~s}, 3 \mathrm{H})$; ESI MS m/z $283.00(\mathrm{M}+\mathrm{H})^{+}$.

## 2,3-Methylenedioxy-6-methoxy-9-bromomethyl-phenanthrene (6)

At $0{ }^{\circ} \mathrm{C}, \mathrm{PBr}_{3}(1.18 \mathrm{~mL}, 12.56 \mathrm{mmol})$ was added dropwise to $5(885 \mathrm{mg}, 3.14 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The ice bath was then removed and the mixture was stirred at room temperature for 3 h before 20 mL sat. $\mathrm{NaHCO}_{3}$ was added. The mixture was extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and washed with brine, dried over $\mathrm{MgSO}_{4}$. Chromatography gave 700 mg product ( $65 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 8.30(\mathrm{~d}, J=9.30 \mathrm{~Hz}, 1 \mathrm{H}), 7.87(\mathrm{~s}, 1 \mathrm{H}), 7.79(\mathrm{~d}, J=2.40 \mathrm{~Hz}, 1 \mathrm{H}), 7.39$ $(\mathrm{s}, 1 \mathrm{H}), 7.22(\mathrm{dd}, J=9.00 \mathrm{~Hz}, J=2.40 \mathrm{~Hz}, 1 \mathrm{H}), 7.15(\mathrm{~s}, 1 \mathrm{H}), 6.08(\mathrm{~s}, 2 \mathrm{H}), 4.68(\mathrm{~s}, 2 \mathrm{H}), 4.00$ (s, 3H); ESI MS m/z $346.05(\mathrm{M}+\mathrm{H})^{+}$.

## General procedure for the synthesis of 9-substituted phenanthrene

Substituted piperidine (in excess) was added to a mixture of bromide and TEA in DMF, which was stirred at room temperature or $60^{\circ} \mathrm{C}$ overnight. DMF was then removed under reduced pressure, and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was used for extraction. The organic layers were combined and sequentially washed with 1 N HCl , sat. $\mathrm{NaHCO}_{3}$ and brine, dried over $\mathrm{MgSO}_{4}$. Chromatography afforded the final products (Yield: $50 \%-90 \%$ ). HCl salt was prepared using 2 M aqueous HCl in MeOH at room temperature.

## Cell growth inhibition assay

The sulforhodamine B assay was used according to the procedures developed and validated at NCI. The in vitro anticancer activities are expressed as IC50 values, which is the test compound concentration $(\mu \mathrm{g} / \mathrm{ml})$ that reduced the cell number by $50 \%$ after 72 h treatment. The values were interpolated from dose-response data. Each test was performed in triplicate with a variation of less than 5\%. The IC50 values determined in each of the independent tests varied less than $10 \%$. Compound stock solutions were prepared in DMSO with the final solvent concentration $\leqq 1 \%$ DMSO (v/v), a concentration without effect on cell replication. The cells were cultured at $37^{\circ} \mathrm{C}$ in RPMI-1640 supplemented with $25 \mathrm{mM} N$-2-hydroxyethylpiperazine$N \phi-2$-ethanesulfonic acid (HEPES), $2 \% ~(\mathrm{w} / \mathrm{v})$ sodium bicarbonate, $10 \%$ ( $\mathrm{v} / \mathrm{v}$ ) fetal bovine serum, and $100 \mu \mathrm{~g} / \mathrm{mL}$ kanamycin in a humidified atmosphere containing $5 \% \mathrm{CO} 2$.

## NF-кB Luciferase assay

Cells were cultured in 12-well plates and transiently co-transfected with $0.2 \mu \mathrm{~g}$ of a pNF- $\kappa \mathrm{B}-$ Luc vector (Stratagene, La Jolla, CA) and $0.2 \mu \mathrm{~g}$ of $\mathrm{pSV}-\beta$ - galactosidase dissolved in $3 \mu \mathrm{~L}$ lipofectamine ${ }^{\mathrm{TM}}$ or lipofectamine ${ }^{\mathrm{TM}} 2000$ (Invitrogen, Carlsbad, CA) as the internal control. The plasmids were transfected according to the manufacturer's instructions. After 6 h, the medium was changed to complete medium and cultured for 6 hours, and then the transfected cells were treated with different compounds in complete medium for 24 hours. Cell extracts were harvested using $150 \mu \mathrm{~L}$ of lysis buffer (Tropix, Inc., Bedford, MA) per well. To measure the luciferase and $\beta$-galactosidase activities, cell extracts ( $20 \mu \mathrm{~L}$ each) were assayed separately using the Luciferase Assay Kit and Galacto-Light Plus ${ }^{\text {TM }}$ system (Tropix, Inc.), respectively. Luciferase activity was measured and analyzed using an FB12 luminometer (Zylux Corporation, Oak Ridge, TN).

## Western Blot Analysis

Cells were treated with different compounds for 48 hours. Equal amounts ( $50 \mu \mathrm{~g}$ ) of cell lysate were separated by $10 \%$ SDS-PAGE, and transferred to a polyvinylidene membrane (Millipore, Billerica, MA). The membrane was probed with antibodies directed against p-Akt, Akt and $\beta$-actin (Sigma, St Louis, MO). Antibodies were diluted in TBS (pH 7.5) containing $0.05 \%$ (v/ v) Tween 20 and $5 \%(\mathrm{w} / \mathrm{v})$ dried milk. Blots were incubated with the appropriate horseradish peroxidase-conjugated secondary antibodies (Amersham Biosciences, Uppsala, Sweden). Bound antibodies were visualized by electrochemical luminescence staining with autoradiographic detection using Kodak X-Omat Blue film (PerkinElmer Life Science, Boston, MA) or Typhoon9410 Variable Mode Imager (Amersham BioScience, Piscataway, NJ)
