1. Overview

Twelve monthly water sample collections and annual invertebrate, habitat and macrophyte surveys have taken place to date. The water chemistry baseline data suggest Site C has the highest nutrient concentrations; habitat and invertebrate data suggest Site A (upstream control) and Site B are largely similar; with macrophyte data suggesting relatively poor habitat. Collated Environment Agency statutory water quality monitoring data for 2016 provide further baseline information (Table 3).

1.1. Annual action summary

- 24/11/15: start-up meeting
- 19/01/16: site selection and initial water sample collection
- 23/02/16: second water sample collection
- 23/03/16: third water sample collection
- 23/03/16: first invertebrate sample collection and habitat survey
- 19/04/16: fourth water sample collection
- 16/05/16: fifth water sample collection
- 16/06/16: sixth water sample collection
- 28/07/16: seventh water sample collection
- 22/08/16: eighth water sample collection
- 22/08/16: first macrophyte survey: Sites A & B
- 22/09/16: ninth water sample collection
- 26/10/16: tenth water sample collection
- 23/11/16: eleventh water sample collection
- 20/12/16: twelfth water sample collection
- 10/01/17: EA statutory monitoring data collated (Table 3)

2. Site information summary

Table 1 Site locations of 50m reaches, see also Figure 1.

Description	Grid Reference	Postcode	Site reference

Figure 1 Site locations.

3. Methods

Upstream and downstream water samples were collected at each site and combined to give mean concentrations of total phosphorus, orthophosphate, total oxidised nitrogen, suspended solids, dissolved oxygen and temperature (*note total phosphorus has been collected since July 2016). Further data collected by the Environment Agency have been collated to complement our data. Physical and biotic assessments were undertaken at Site A (upstream control) and Site B (designated for restoration): substrate proportions (i.e. %silt relative to other substrate), wood and plant percentage volume infested (PVI) were estimated at each invertebrate survey point (n = 12, i.e. 6 samples per reach).

3.1. Biotic characterisation

A bespoke 152.4mm diameter Hess sampler with 335 microns mesh was used to collect invertebrates. Unlike a kick net survey, Hess samples are quantitative meaning population densities can be estimated. A row of teeth at the base of the Hess and robust handles enabled it to cut through branches when used within woody structures. Samples were immersed immediately in 70% IMS to preserve contents for identification in the laboratory. Invertebrates were identified to species in most cases using a dissecting microscope with 40-100x magnification and counted to give the density per sample.

3.2. Macrophyte survey

Sites A and B were surveyed for aquatic macrophytes. Each 50 m reach was subdivided into 10 x 5 m sections and at each section a percentage cover was estimated for all plants found growing within a) the channel under normal flow conditions (i.e. aquatic plants) and b) on the bank (defined by the area between the waterline and bank-full). Additional records were made of substrate, shading, and general bank character. Plant identification was performed in the field where possible, and, where necessary, in the laboratory from voucher specimens.

3.3. Statistical methods

The principal aim of this report is to develop a baseline for the Gilwiskaw Brook and River Mease ecosystems. First we show how water chemistry differs between sites and over time. We use Tukey contrasts on linear models to test for water chemistry differences between sites, after accounting for seasonal effects. We then focus in on whether abiotic and biotic conditions between the control (Site A) and pre-restored (Site B) reaches differ. We use principal components analysis (PCA) and non-metric multidimensional scaling (NMDS) with the Bray–Curtis dissimilarity index to assess differences in environmental parameters and invertebrate composition, respectively.

Estimates of species richness were made using recently developed methodology published as the R package iNEXT (Chao *et al.* 2014). This approach provides information on the sampling efficiency (i.e. estimates what percentage of the community we are capturing) and provides a robust means of comparing samples where different sample sizes occur. In NMDS and species richness estimates, groups such as oligochaetes and chironomids were removed due to large within group diversity which can distort such analyses. “Reach” was a fixed term and “sample” was a random term in general linear mixed effects models (GLMM) used to assess differences in invertebrate density and biomass.

4. Results

There were seasonal trends in water chemistry variables, such as summer and winter peaks in suspended solid concentration (Figure 2 and see Table 4 in Appendix I). Concentrations of orthophosphate and total oxidised nitrogen were highest at Site C, and dissolved oxygen was lowest at Sites C and E. By comparing our data with those collected by the Environment Agency we were able to reveal that the elevated nutrient concentrations at Site C were driven by those coming from the R. Mease upstream of the confluence with G. brook (Table 3).

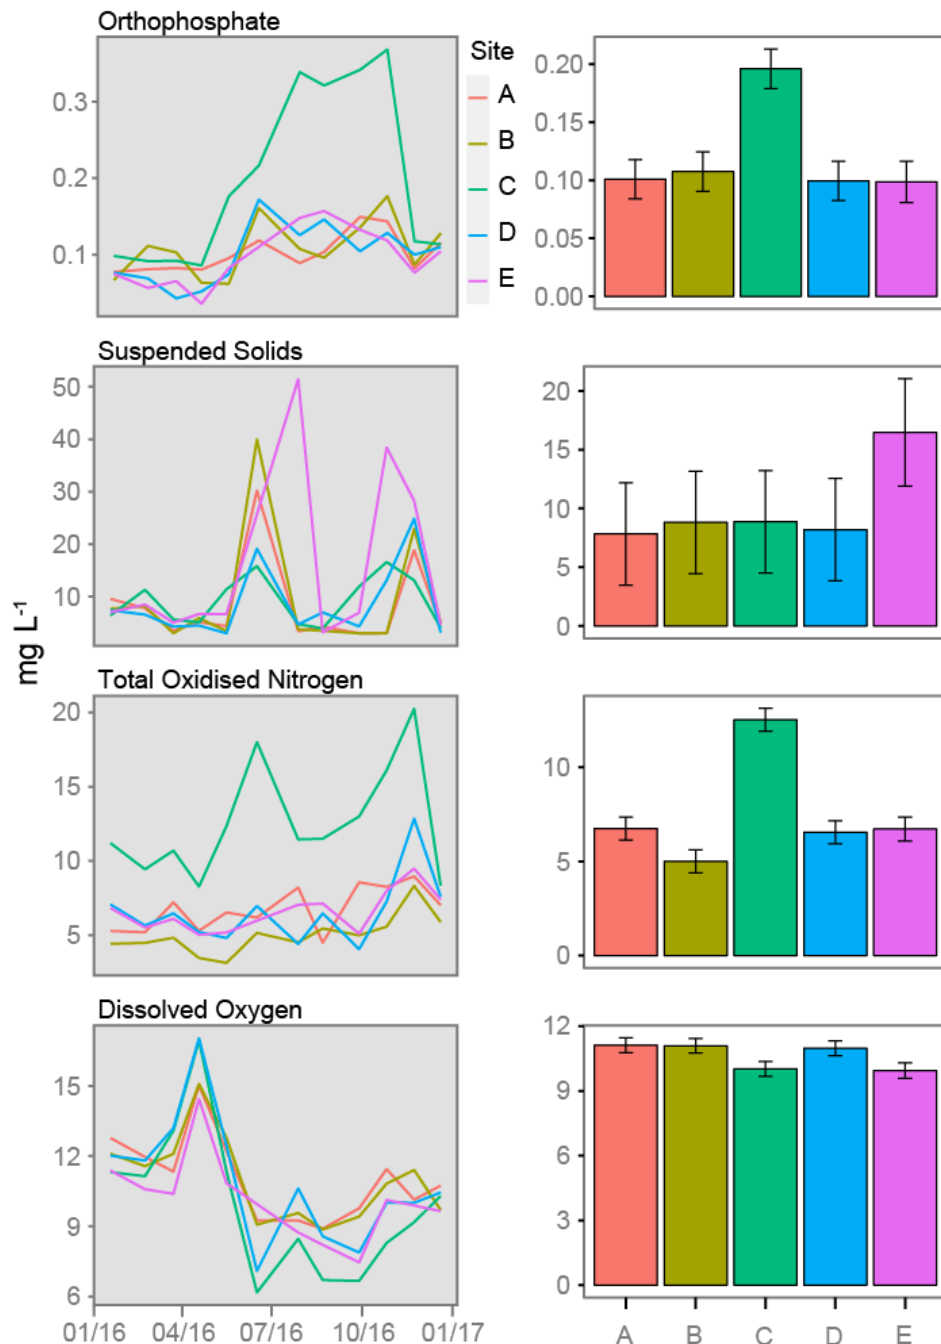

Figure 2 Left column: time series mean water chemistry data across sites. Right column: between site differences in water chemistry, error bars represent 95% confidence intervals.

Table 2 Annual mean water chemistry data for 2016. TON = total oxidised nitrogen which is the sum of nitrate (NO₃⁻) and nitrite (NO₂⁻).

	A	B	C	D	E
Dissolved oxygen (mg L⁻¹)	11.07	11.04	9.97	10.93	10.15

Temperature °C	12.83	15.58	10.36	10.15	10.48	9.65
Conductivity (µS-cm)	691.83	748.4	670.43	862	964.25	819.12
pH	8.12	7.98	7.99	7.98	7.83	7.93

There were no significant differences in habitat variables between Site A or B, but there was a significant difference in invertebrate community composition (Figure 3a, b, see Table 5 in Appendix II). This compositional difference was likely due to presence of *Ancylus fluviatilis*, *Asellus aquaticus*, *Clinocera* spp. only in Site A, and *Caenis lactuosa*, *Halesus radiatus* and *Polycentropus flavomaculatus* only recorded in site B, among other taxa. There were no significant differences in invertebrate species richness, abundance and biomass between sites (Figure 3c, d, e).

Baseline macrophyte data show there to be very low species richness within the river channel at sites A and B. With the exception of *Lemna minor* (Duck weed), which was recorded in the slack water areas of Site A, the submerged flora comprised only of bryophytes, and these were mainly restricted to areas which are periodically exposed (at low flow). Site A is heavily shaded by tree growth, thus limiting the development of marginal vegetation. The species summaries are given below and full data presented in Appendix III.

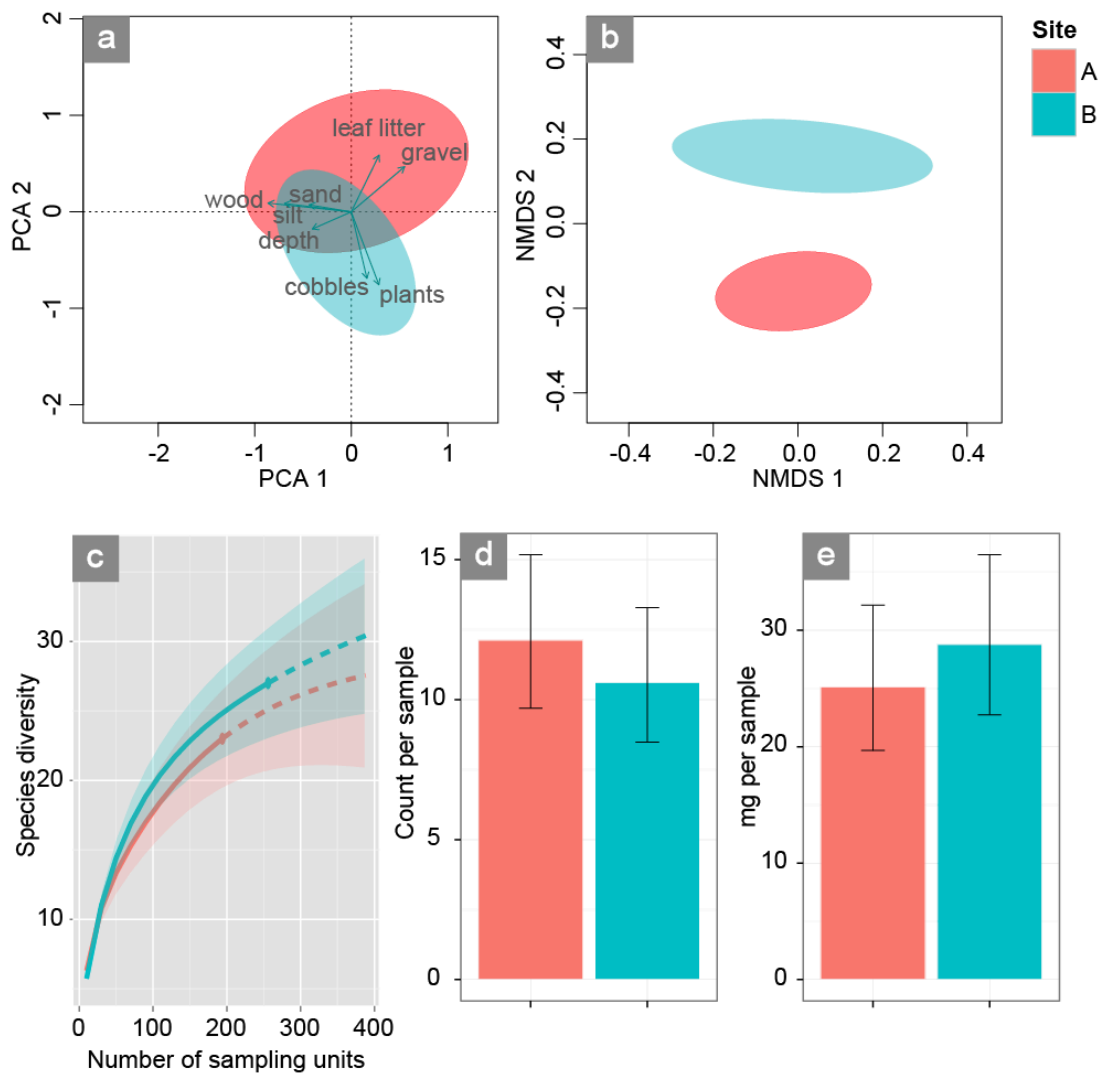

Figure 3 a) PCA of habitat data, ellipses represent standard error; b) NMDS of species data, ellipses represent standard error; c) species richness estimation, shading represents 95% confidence intervals, dotted lines indicate extrapolation from observed diversity (solid line) towards a standardised sample size (i.e. 388); d) differences in invertebrate abundance and e) biomass per sample, error bars represent 95% confidence intervals..

4.1. Macrophytes: Site A - SK3600014177 - SK3598714131

This section is heavily shaded (>90%) by overhanging trees on both banks. With the exception of occasional fronds of *Lemna minor* (common duckweed) held up in the margins, there were no higher plants growing within the channel. Bryophytes were relatively common just above the waterline and occasional within the channel.

The banks are steep sloping (45 degrees to vertical) and dominated by tall trees – mainly alder and sycamore with an understory of hawthorn, holly and elder with brambles (*Rubus fruticosus* agg.) beneath.

Species summary – Channel (overall for 50 m reach)

Name	Abundance	Cover
<i>Lemna minor</i>	Rare	<1%
<i>Pellia epiphylla</i> (thallose liverwort)	Rare	<1%
<i>Fissidens viridulus</i> (moss)	Rare	<1%
<i>Oxyrrhynchium hians</i> (moss)	Rare	<1%
Filamentous green algae	Frequent	<20%

Substrate: Pebbles (65%), Cobbles (20%), Gravel (10%), Fines (5%).

Species summary – Bank (overall for 50 m reach)

Name	Abundance	Cover
<i>Pellia epiphylla</i> (thallose liverwort)	Frequent	<25%
<i>Fissidens viridulus</i> (moss)	Occasional	<5%
<i>Leptodictyum riparium</i> (moss)	Occasional	<5%
<i>Oxyrrhynchium hians</i> (moss)	Occasional	<5%
<i>Alnus glutinosa</i>	Abundant	<50%
<i>Carex pendula</i>	Frequent	<25%
<i>Crataegus monogyna</i>	Frequent	<25%
<i>Crocsmia</i> sp*.	Rare	<1%
<i>Ilex aquifolium</i>	Occasional	<5%
<i>Lamium album</i>	Rare	<1%
<i>Phalaris arundinacea</i>	Occasional	<5%
<i>Rubus fruticosus</i> agg.	Frequent	<25%
<i>Sambucus nigra</i>	Rare	<2%
<i>Stachys sylvestris</i>	Rare	<1%
<i>Urtica dioica</i>	Occasional	<5%

*Non-native species – garden escape

4.2. Macrophytes: Site B - SK3615012427 - SK 3613712381

This section lies in a deeply incised channel (approx. 2 m below field height) with partial shade by overhanging trees/shrubs on both banks. There were no higher plants growing within the channel. Bryophytes were relatively common just above the waterline and occasional within the channel.

The banks are steep sloping (60 degrees to vertical) and dominated by tall grasses on the east bank and mainly brambles and tall herbs on the west bank.

Species summary – Channel (overall for 50 m reach)

Name	Abundance	Cover
<i>Pellia epiphylla</i> (thallose liverwort)	Rare	<1%
<i>Brachythecium rutabulum</i>	Rare	<1%
Filamentous green algae	Dominant	>65%
<i>Vaucheria</i> sp. (algae)	Dominant	>10%

Substrate: Pebbles (30%), Cobbles (20%), Gravel (20%), Fines (20%) Boulders (10%).

Species summary – Bank (overall for 50 m reach)

Name	Abundance	Cover
<i>Pellia epiphylla</i>	Occasional	<5%
<i>Brachythecium rutabulum</i>	Rare	<2%
<i>Fissidens viridulus</i>	Rare	<2%
<i>Agrostis stolonifera</i>	Occasional	<5%
<i>Angelica sylvestris</i>	Rare	<1%
<i>Carex pendula</i>	Occasional	<5%
<i>Cirsium palustre</i>	Rare	<1%
<i>Crataegus monogyna</i>	Rare	<2%
<i>Epilobium hirsutum</i>	Frequent	<15%
<i>Filipendula ulmaria</i>	Rare	<1%
<i>Impatiens glandulifera</i> *	Rare	<1%
<i>Juncus effusus</i>	Rare	<1%
<i>Juncus inflexus</i>	Rare	<2%
<i>Phalaris arundinacea</i>	Dominant	>50%
<i>Scrophularia auriculata</i>	Occasional	<5%
<i>Stachys palustris</i>	Occasional	<5%

The moss *Brachythecium rutabulum* recorded in the channel was mainly confined to the tops of larger boulders and stones, suggesting it is exposed at low flow.

*Himalayan Balsam – a non-native invasive species. Care should be taken not to spread this species during any management action. We would advise manual control during spring and summer.
