

Imidazolyl Alanes

Imidazolyl Alanes – Synthesis, Structures, and Reactivity Studies

Martin Simon,^[a] Michael Radius,^[a] Hanna E. Wagner,^[a] and Frank Breher^{*[a]}

Abstract: Targeting the synthesis of Al/C based ambiphilic molecules, we investigated the dehydrohalogenation of a series of (benz)imidazole alane adducts. Depending on the steric bulk of the heterocycle, different dimeric products with various ring sizes were obtained. Dehydrohalogenation of the adduct of 1-mesityl imidazole (^{Mes}Im) and 0.5 [tBu₂AlBr]₂ furnished the dimer **2**, featuring a “classical” N-heterocyclic carbene (NHC) and a mesoionic or “abnormal” NHC (aNHC) subunit within a single molecule. The dimer is bound loosely enough to allow thermally induced isomerization of **2** into the isomers **2^{NHC}** (all NHC) and **2^{aNHC}** (all aNHC). Dehydrohalogenation of the adduct of 1-mesityl-2-methyl imidazole (^{Mes}ImMe) and 0.5 [tBu₂AlBr]₂ (**4**)

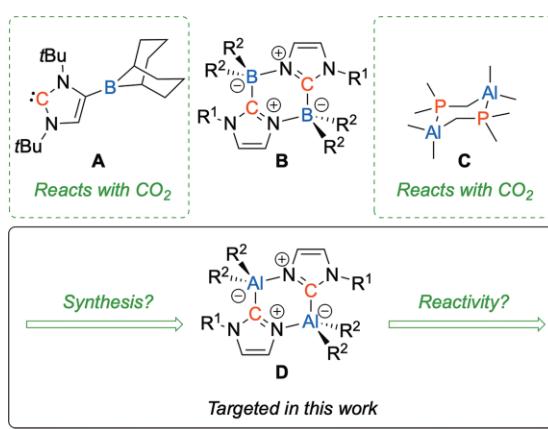

yielded the dimeric compound **5** consisting of two N-heterocyclic olefin (NHO) subunits. Although these six- and eight-membered heterocycles show no FLP-type reactivity towards small molecules like H₂, CO or CO₂, we observed an ambiphilic behavior of the imidazolyl alanes during our studies. Salt metathesis reactions using ^{Mes}Im resulted in the formation of **3**, which can be viewed as tBu₂AlBr adduct of an Al/N ambiphile. Utilizing heterocycles such as benzimidazole or spiroindole provided the entry point to C–H (**7**, **9**) and N–H (**10**) activation products, most likely resulting from a reactivity of intermediate species as Al/C ambiphiles.

Introduction

Since the concept of frustrated Lewis pairs (FLPs) was introduced some years ago, this research topic has emerged to one of the most intensively studied fields in modern p-block chemistry.^[1] The adjustable properties of Lewis-acidity, -basicity and sterics allow for a tailored reaction control of both intra- and intermolecular systems, which enabled a remarkable development. FLPs were investigated in various chemical processes, broadening research subjects to multifarious application fields such as activation and fixation of small molecules, catalysis or as ambiphilic ligands.^[1b,2]

Alongside of the “classical” combination of compounds based on group 13 and group 15 elements, which still is dominated by the archetypal B/P-pairing,^[3] also B/N-,^[4] Al/P-,^[5] Ga/P-,^[5h,5n,6] and In/P-combinations^[6a,6b] have recently been established, among others. Furthermore, considerable efforts have been made in developing Lewis-acidic group 14 and Lewis-basic group 15 combinations.^[3,4],7–11] Few examples for FLPs comprising heavy group 14 Lewis bases^[10c,12] or other nucleophilic C-bases are known,^[13] and some of the so far re-

ported intermolecular FLPs comprise N-heterocyclic carbenes (NHC) and derivatives thereof^[10a,14] as Lewis-basic component. Intramolecular systems still remain scars in literature. Tamm et al. were the first to report a backbone-functionalized NHC featuring a borane unit in the NHC backbone (**A**, Scheme 1).^[15] As reported for most FLP systems, the reactive functional entities are spatially separated to provide “frustration”. Recently, Liu et al. showed that deprotonation of an *N*-boryl-substituted imidazolium salt resulted in the intermediate formation of an *N*-boryl-substituted NHC, which underwent an 1,2-migration yielding a C-imidazolyl-borane (**B**, Scheme 1).^[16] Such compounds exhibit a strong tendency for dimerization as shown additionally by others with various substituents.^[16,17] The structural motif **B** features an interesting starting point concerning a reactivity as hidden FLP/active Lewis Pair.^[18]

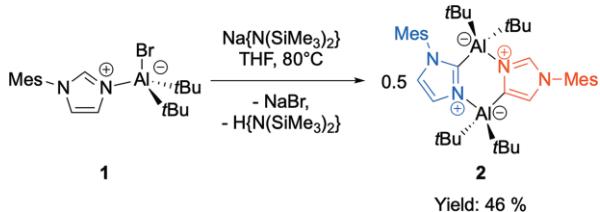

Scheme 1. Structures of a B/C-based FLP **A**, dimeric imidazolylboranes **B** and an Al/P Lewis Pair (**C**) that reacts with CO₂.

Although several compounds with this architecture were described,^[16,17] no reactivity studies for such with small molecules were reported until now. Inspired by our earlier findings on hidden aluminum phosphorus FLPs^[19] and related B/C combinations^[20] as well as the dimeric FLP **C** reported by Fontaine et al.,^[21] we targeted imidazolyl-alanes (**D**) bearing a highly Lewis acidic aluminum atom in geminal position to the Lewis base. We anticipated that such dimers might show FLP-type reactivity, either as Al/C or Al/N FLP, depending on steric and electronic effects of the substituents. Herein we report our efforts in preparing imidazolyl alanes with various substituent patterns.

Results and Discussion

Alane-Substituted NHCs

The synthesis of an imidazolyl alane was attempted by dehydrohalogenation of $^{Mes}Im\cdot tBu_2AlBr$ **1** (see Experimental Section for the synthesis) by $Na\{N(SiMe_3)_2\}$ in THF at 80 °C yielding compound **2** (Scheme 2, ^{Mes}Im = 1-mesityl imidazole). The product was isolated after recrystallization from hot toluene in 46 % yield. Interestingly, the deprotonation of the imidazoles selectively took place at two different positions of both heterocycles. Hence, **2** features a “classical” NHC and a mesoionic or “abnormal”^[22] NHC subunit within a single molecule as evidenced by two carbene resonances in the $^{13}C\{^1H\}$ NMR spectrum (δ = 169.8 ppm for NHC and 150.8 ppm for aNHC, respectively). Additionally, four ^{15}N NMR chemical shifts and two well-separated sets of 1H NMR resonances were detected.

Scheme 2. Dehydrohalogenation of **1** leading to formation of **2**. Blue indicates the NHC subunit, red the aNHC subunit.

The solid-state structure (Figure 1) revealed a non-planar topology for the central $Al_2C_2N_2$ ring system, which exhibits a torsion of 25.8° along $Al1-C1-N2-Al2$. Both aluminum atoms adopt distorted tetrahedral geometries. The $Al-C^{NHC}$ bond [$d_{C1-Al1} = 207.3(2)$ pm] is elongated as compared to the $Al-C^{aNHC}$ bond [$d_{C5-Al2} = 199.1(2)$ pm], which is most likely induced by steric repulsion of the Mes and *t*Bu substituents. Nevertheless, these bond lengths are in line with reported aluminum NHC and aNHC compounds.^[23] In contrast to the $Al-C$ carbene bonds, the aluminum nitrogen distances of $d_{Al1-N3} = 196.0(2)$ pm $d_{Al2-N2} = 194.4(2)$ pm differ only slightly. It has to be noted that for dimeric imidazolyl boranes and triazolyl alanes, exclusively C_2 or C_s symmetric species, deprotonated at the C2-position, were reported, highlighting the unique structure of **2**.^[16,17,24]

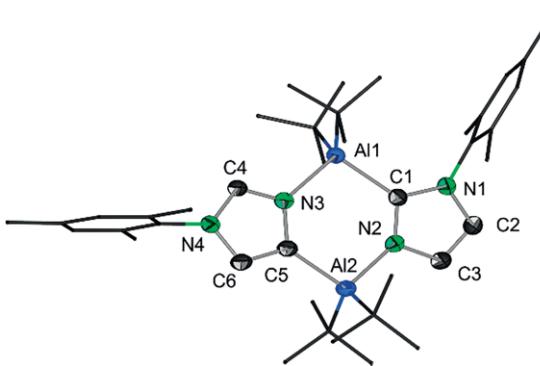

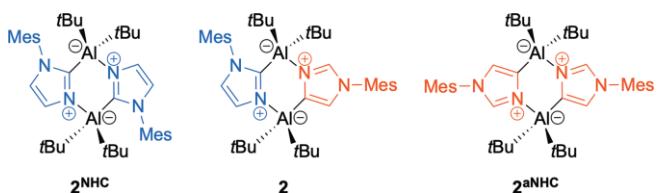

Figure 1. Molecular structure of **2** (30 % probability ellipsoids; hydrogen atoms are omitted and *t*Bu and Mes groups are displayed as wire for clarity; space group $P\bar{1}$). Selected bond lengths [pm] and angles [°]: $Al1-C1$ 207.3(2), $Al2-C5$ 199.1(2), $Al1-N3$ 196.0(2), $Al2-N2$ 194.4(2), $C1-N2$ 135.5(3), $C5-N3$ 140.3(3), $N1-C1-N2$ 105.8(2), $C6-C5-N3$ 105.7(2), $C1-Al1-N3$ 101.8(8), $C5-Al2-N2$ 101.9(8), $Al2-N2-C1$ 132.3(1), $Al1-N3-C5$ 130.3(1).

Since the 1H NMR spectra of **2** showed the presence of further species in traces, which exhibit the same coupling pattern as **2**, a *pro rata* generation of the isomers **2^{NHC}** and **2^{aNHC}** was suggested (Scheme 3). Hence, thermal conversion of **2** into the symmetric species was investigated. Heating a sample of **2** to 80 °C in C_6D_6 led to an intensity decrease of the 1H NMR resonances of **2**, while the trace signals gained in intensity until an equilibrium of approximately $1 \times 2^{NHC} + 2 \times \mathbf{2} + 1 \times 2^{aNHC}$ was achieved, which corresponds to the statistic distribution of the subunits. Combined 2D NMR spectroscopic methods enabled the correlation of the imidazolium ring resonances to the **2^{NHC}** and **2^{aNHC}** isomers formed by thermal isomerization (see Supporting Information for details).

Scheme 3. Products **2^{NHC}**, **2** and **2^{aNHC}** by thermal isomerization of **2**. Blue indicates the NHC subunit, red the aNHC subunit.

Additionally, single crystals of **2^{aNHC}** suitable for X-ray diffraction studies were obtained from the reaction mixture (Figure 2). The $Al1-C3$ bond [199.1(3) pm] is almost equal to **2** [cf. $d_{Al2-C5} = 199.1(2)$ pm] and the same applies to the $Al1-N2$ bond of 195.7(3) pm [**2**: cf. $d_{Al1-N3} = 196.0(2)$ pm].

The observed isomerization provided evidence that the central ring system of **2** is able to open up, which might result in the presence of a free Lewis-acid and -base in the solution, thus enabling FLP reactivity. Reactivity studies on **2** with small molecules such as H_2 , CO , CO_2 , COS , CS_2 and benzaldehyde in C_6D_6 , however, revealed that no reactivity as hidden FLP is given, neither at ambient nor at elevated temperatures. Since in presence of the substrates also isomerization of **2** to **2^{NHC}** and **2^{aNHC}** was observed, it has to be concluded that also the latter two isomers show no FLP reactivity.

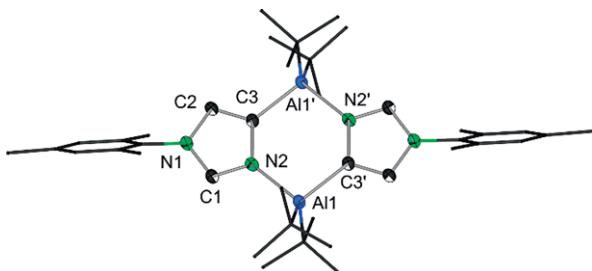

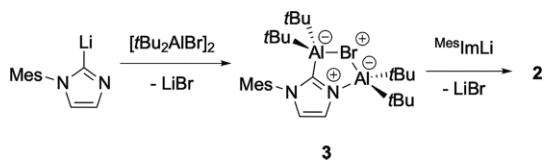

Figure 2. Molecular structure of **2^aNHc** (30 % probability ellipsoids; hydrogen atoms and solvent molecules are omitted and tBu and Mes groups are displayed as wire for clarity; space group $P\bar{1}$). Equivalent atoms are generated by $1 - x$, $2 - y$, $1 - z$. Selected bond lengths [pm] and angles [$^\circ$]: Al1'-C3 199.1(3), Al1-N2 195.7(3), N2-C3 140.6(3), N2-C1 132.9(4), N2-Al1-C3 103.21(11), Al1-N2-C3 125.4(2), N2-C3-Al1' 125.4(2).

Although it seems to be clear that, once the six-membered heterocycles are formed, no FLP reactivity towards small molecules can be detected any more, we nonetheless observed ambiphilic behavior of the imidazolyl alanes during our studies. In an attempt to generate pure **2^{NHc}**, in situ generated lithium salt $^{Mes}ImLi$ was applied in salt metathesis reactions with different amounts of $[tBu_2AlBr]_2$ (Scheme 4). As proved by a previous hydrogen-deuterium-exchange experiment, ^{Mes}Im can be selectively deprotonated in C2-position by $nBuLi$ (further experimental details are given in the Supporting Information). The subsequent reaction with $[tBu_2AlBr]_2$ allowed for two interesting observations, namely 1) instead of isolating the six-membered ring compound **2^{NHc}**, the asymmetric dimer **2** featuring both an NHC and an aNHC subunit has been isolated. Hence, a proton-coupled rearrangement has occurred, which has, however, already been reported by others.^[14a,23e] 2) We were able to isolate and characterize compound **3** (Scheme 4), which can be viewed as adduct of monomeric imidazolyl alane with tBu_2AlBr . Compound **3** is stable for several months at ambient temperature under Schlenk conditions, as isolated compound, as well as in solution (C_6D_6 , hexane). The product **3** consists of a ^{Mes}Im unit, deprotonated at the C2-position ($\delta^{13}C = 170.0$ ppm) and one tBu_2Al group bound to C2 ($\delta^{1H} = 1.09$ ppm) and one to the N-terminus ($\delta^{1H} = 1.25$ ppm). The bromide adopts the bridging position between both aluminum entities.

Scheme 4. Stepwise synthesis of **2** via **3** in hexane at RT.

Since we only were able to obtain single crystals of poor quality, we performed some density functional theory studies (Figure 3). These show an Al1-C1 distance of 209.2 pm and an Al2-N2 bond length of 196.1 pm. Compared to the Al2-Br1 distance of 248.3 pm, Al1-Br1 was found to be much longer (256.6 pm). Analysis of the Wiberg bond indices additionally suggest a slightly stronger Al2-Br bond (0.58) as compared to the Al1-Br counterpart (0.43). Based on these findings it ap-

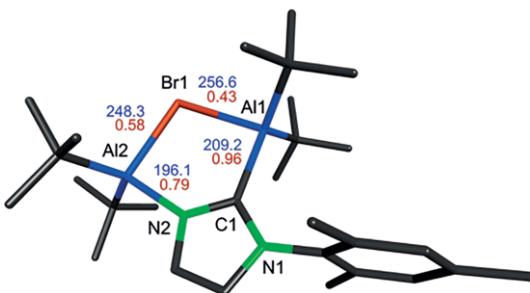

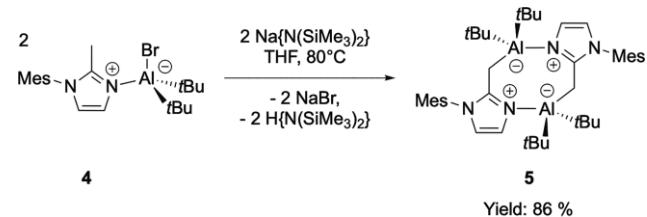

Figure 3. Calculated [(ri)-def2-TZVP/B3-LYP] molecular structure of **3**. Blue numbers indicate calculated bond lengths, red numbers the Wiberg bond indices. Hydrogen atoms are omitted for clarity.

pears that **3** can be described as tBu_2AlBr adduct of an Al/N ambiphile.

Alane-Substituted NHOs

In an attempt to selectively deprotonate the backbone of imidazole, a methyl group was introduced on C2 of ^{Mes}Im . The preparation of $^{Mes}Im^{Me}$ was executed by a straightforward synthetic route, via deprotonation of ^{Mes}Im with $nBuLi$ and subsequent reaction with MeI in toluene. The addition of stoichiometric amount of $[tBu_2AlBr]_2$ to $^{Mes}Im^{Me}$ furnished the respective adduct **4**. Dehydrohalogenation of **4** led to the formation of bis(alane) **5** (Scheme 5). Astonishingly, deprotonation of $^{Mes}Im^{Me}$ apparently took place at the methyl group instead of the backbone leading to the N-heterocyclic olefin (NHO) structure.

Scheme 5. Dehydrohalogenation of **4** resulting in the bis(alane) **5**.

The solid-state structure of **5** displays a nearly C_2 symmetric species (Figure 4). Neither the Al-N nor the Al-C^{carbene} distances of **5** differ significantly from **2** or **2^aNHc**. As already observed for the latter two compounds, no reaction of **5** with H_2 , CO_2 , COS or CS_2 was observed in C_6D_6 .

Alane-Substituted Benzimidazoles

Targeting the sterically more crowded heterocycles, benzimidazole derivatives were used as precursors. Utilizing 1-methylbenzimidazole (^{Me}BIm) as organic scaffold, the adduct $^{Me}BIm \cdot tBu_2AlBr$ (**6**) was prepared by addition of 0.5 $[tBu_2AlBr]_2$ in toluene. Subsequent dehydrohalogenation using $Na[N(SiMe_3)_2]$ in THF, however, again furnished an unexpected product (**7**, Scheme 6). As evidenced by NMR spectroscopic and X-ray crystallographic studies (Figure 5), a C-C bond formation between two heterocycles has been accomplished. The depro-

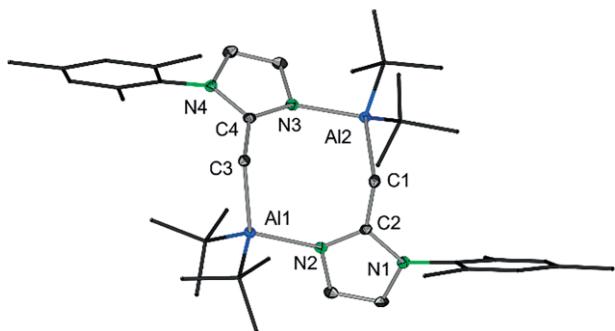

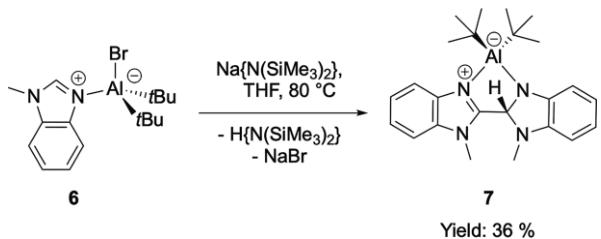

Figure 4. Molecular structure of **5** (30 % probability ellipsoids; hydrogen atoms are omitted and tBu and Mes groups are displayed as wire for clarity; space group P_2_1/n). Selected bond lengths [pm] and angles [$^\circ$]: C1–C2 145.3(3), C2–N1 136.5(3), C2–N2 133.8(3), N2–Al1 196.9(2), Al1–C3 203.8(2), C3–C4 146.3(3), C4–N4 136.3(3), C4–N3 133.7(3), N3–Al2 195.8(2), Al2–C1 203.2(2), N1–C2–N2 108.4(2), N4–C4–N3 108.4(2), C2–N2–Al1 131.4(2), N2–Al1–C3 110.8(9), C4–N3–Al2 132.8(2), N3–Al2–C1 110.5(9).

tonation of one ^{Me}Blm subunit suggested the intermediate formation of an alane-substituted NHC which underwent a C–H insertion at a second equiv. of ^{Me}Blm . Such reactivity was suggested for the formation of cyclene, leading to an analogue structural motif.^[25] This at least strongly indicates the reactivity of the intermediate species as Al/C ambiphile. Another possibility would be the sequence: a) deprotonation of **6** and addition of the carbene to the electrophilic carbon atom of another molecule of **6**, with release of tBu_2AlBr .

Scheme 6. Synthesis of **7** from **6**.

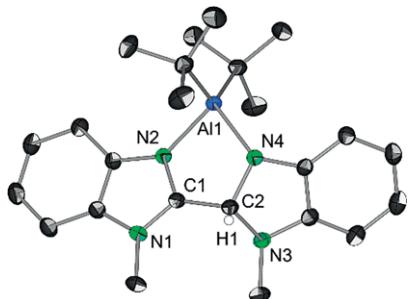

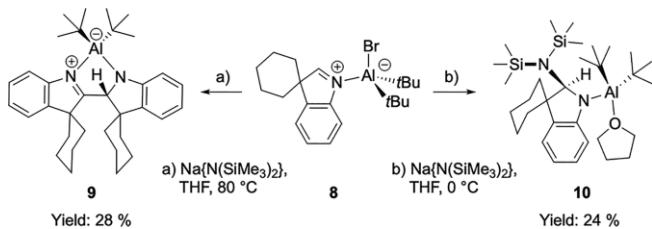

Figure 5. Molecular structure of **7** (30 % probability ellipsoids; hydrogen atoms except at C11 are omitted for clarity; space group $P\bar{1}$). Selected bond lengths [pm] and angles [$^\circ$]: Al1–N2 197.6(1), Al1–N4 188.8(1), C1–N2 134.6(2), C2–N4 147.8(2), C1–C2 146.3(2), N2–Al1–N4 85.2(5), Al1–N4–C2 115.8(9), N4–C2–C1 107.2(1), C2–C1–N2 119.6(1), C1–N2–Al1 110.7(9).

An analogous reaction was observed using precursor **8** featuring a spiroindole-scaffold (Scheme 7). Depending on the reaction conditions, either the C–H activation product **9**^[22] or the N–H activation product **10** (Scheme 7, Figure 6) was isolated.

In each case, the products can be rationalized as insertion products of an *N*-alane-substituted CAAC^[26] into a C–H (**9**) or an N–H bond (**10**). Such insertion of regular CAACs into various E–H bonds are known from the literature.^[27] Again, and as discussed above, the reaction products may also result from nucleophilic addition reactions of a carbene (**9**) or and amide (**10**) to the electrophilic carbon atom of **8**, with release of tBu_2AlBr (**9**) or bromide from aluminum (**10**).

Scheme 7. Temperature-dependent preparation of **9** and **10** from **8**.

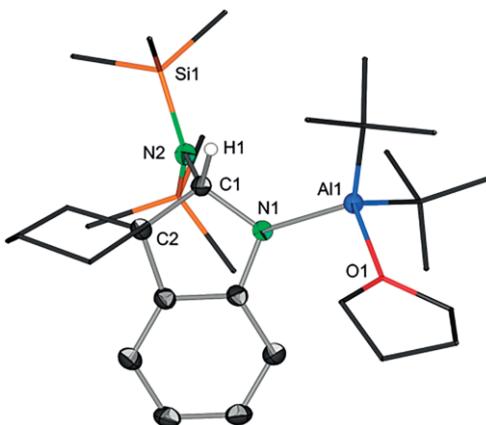

Figure 6. Molecular structure of **10** (30 % probability ellipsoids; hydrogen atoms except at C1 are omitted and bulky groups are displayed as wire for clarity; space group $P\bar{1}$). Selected bond lengths [pm] and angles [$^\circ$]: Al1–N1 187.6(2), N1–C1 148.8(2), C1–N2 149.5(2), N2–Si1 176.0(2), N2–Si2 176.3(2), Al1–N1–C1 124.4(1), N1–C1–N2 114.6(1).

Conclusions

The dehydrohalogenation of a series of (benz-)imidazole alane adducts resulted in a variety of products depending on the steric bulk of the heterocycle. Utilizing ^{Mes}Im yielded **2**, which comprises two different subunits. Thermally induced isomerization of **2** was observed to provide a statistically distributed mixture of the isomers **2**, **2^{NHC}** or **2^{aNHC}**. Dehydrohalogenation of methylated **4** afforded the sterically unencumbered NHO adduct **5**. Although these six- and eight-membered heterocycles show no FLP-type reactivity with small molecules like H₂, CO or CO₂, we observed an ambiphilic behavior of the imidazolyl alanes during our studies. Salt metathesis reactions using ^{Mes}Im resulted in the formation of **3**, which can be viewed as tBu_2AlBr adduct of an Al/N ambiphile. Utilizing heterocycles such as benzimidazole or spiroindole provided the entry point to C–H (**7**, **9**) and N–H (**10**) activation products most likely resulting from a reactivity of intermediate species as Al/C ambiphiles. Further adjusting the sterics of both the heterocycles and the

substituents on aluminum might bear the potential for the generation of a monomeric imidazolyl-alane that could act as FLP. Indications for this have been provided by this study.

Experimental Section

General

All manipulations were performed under an argon atmosphere using standard Schlenk techniques.^[28] All solvents were freshly distilled under argon from sodium and benzophenone (THF, toluene, hexane) or CaH₂ (dichloromethane) prior to use. C₆D₆ and [D₈]tBu were distilled under argon from potassium/benzophenone prior to use. Air sensitive compounds were stored and weighed in glove boxes (Braun MB150 G-I and Unilab system). Solution NMR spectra were recorded using Bruker Avance instruments operating at ¹H Larmor frequencies of 300 or 400 MHz; chemical shifts are given relative to TMS for ¹³C and ¹H. Coupling constants J are given in Hertz as positive values regardless of their real individual signs. The multiplicity of the signals is indicated as s, d, t, q, m, dd, dt, td, or ddd for singlets, doublets, triplets, quartetts, multiplets, doublets of doublets, doublets of triplets, triplets of doublets or doublet of doublets of doublets, respectively. The abbreviation br is given for broadened signals. NMR samples were prepared in oven-dried 5 mm NMR tubes and sealed under argon. Standard Bruker software routines (TOPSPIN) were used for the 1D and 2D NMR measurements. IR spectra were recorded on a Bruker Alpha FT-IR spectrometer using the ATR technique (attenuated total reflection) on bulk material, and the data are quoted in wavenumbers (cm⁻¹). The intensities of the absorption bands are indicated as vs. (very strong), s (strong), m (middle), w (weak), vw (very weak). Mass spectra and elemental analyses were recorded by the institutional technical laboratories of the Karlsruhe Institute of Technology (KIT).

All precursors were purchased from commercial sources and used as received. Mesityl imidazole,^[29] spiro[cyclohexane-1,3'-indole],^[30] [tBu₂AlBr]₂,^[31] [tBu₃Al],^[32] and [tBu₂AlH]₃^[32] were prepared according to literature procedures. The compounds 1-mesityl-2-methyl-imidazole and spiro[cyclohexane-1,3'-indole] were described in the literature before. However, a modified synthesis is added in the Supporting Information for completeness. They also contain further information of the thermal isomerization of compound **2** and the selective deuteration of MesIm.

Synthetic Procedures for Compounds 1–10

Synthesis of Compound 1: MesIm (1.118 g; 6.000 mmol; 1.0 equiv.) and [tBu₂AlBr]₂ (1.327 g; 3.000 mmol; 0.5 equiv.) were placed in a Schlenk tube and dissolved in 20 mL of toluene. After 30 min the solvent was evaporated, and the crude product was crystallized from hot toluene by cooling to -20 °C. MesIm·tBu₂AlBr **1** (2.368 g; 5.813 mmol; 97 %) was isolated as colorless crystals. M.p.: 133 °C; ¹H NMR (300 MHz, C₆D₆): δ [ppm] = 7.89 (t, ⁴J_{HH} = 1.3 Hz, H1, 1H), 7.14 (t, J_{HH} = 1.4 Hz, H3, 1H), 6.46 (d, ⁴J_{HH} = 0.6 Hz, m-Mes, 2H), 5.86 (t, H2, J_{HH} = 1.5 Hz), 2.00 (s, p-CH₃(Mes), 3H), 1.44 (s, o-CH₃(Mes), 6H), 1.36 (s, tBu, 18H); ¹³C{¹H} NMR (75 MHz, C₆D₆): δ [ppm] = 140.2 (p-Mes), 139.7 (C1), 134.6 (i-Mes), 131.5 (o-Mes), 129.4 (m-Mes), 126.9 (C3), 121.7 (C2), 30.6 [C(CH₃)₃], 20.8 (p-CH₃-Mes), 16.7 (o-CH₃-Mes), 16.1 [C(CH₃)₃]; ¹⁵N NMR (30 MHz, C₆D₆): δ [ppm] = 209.1 (s, N^{Al}), 181.0 (s, N^{Mes}); IR (ATR; cm⁻¹): ̄ = 3141 (vw), 2944 (w), 2921 (w), 2909 (w), 2888 (vw), 2865 (w), 2828 (m), 2157 (vw), 1612 (vw), 1521 (m), 1502 (w), 1461 (m), 1381 (vw), 1358 (vw), 1275 (w), 1230 (w), 1175 (vw), 1111 (s), 1097 (m), 1063 (vs), 1034 (vw), 1001 (w), 973 (w), 959 (m), 936 (vw), 856 (m), 812 (vs), 759 (s), 731 (vw), 670 (s), 653 (m), 592 (m), 576 (m), 541 (w),

498 (vw), 437 (m), 411 (vs), 391 (m); HRMS (EI): m/z calcd. for [C₁₆H₂₃AlN₂Br]: 349.0860 + 351.0840 [M-C₄H₉], found 349.0194 + 351.0168; elemental analysis calcd. (%) for [C₂₀H₃₂AlN₂Br]: C 58.97, H 7.92, N 6.88, Al 6.62, Br 19.61; found C 59.16, H 7.618, N 6.83.

Synthesis of Compound 2: MesIm·tBu₂AlBr (**1**) (1.044 g; 2.563 mmol; 0.5 equiv.) and Na[N(SiMe₃)₂] (470 mg; 2.563 mmol; 0.5 equiv.) were suspended in 40 mL of THF and heated to 80 °C for a period of 24 h. After cooling to ambient temperature, the solvent was removed, the residue suspended in 20 mL of toluene and filtered. The filtrate was evaporated to dryness, the residue was suspended in pentane (2 × 5 mL) and the supernatant was removed. The crude product was crystallized from a saturated solution of hexane at 4 °C giving **2** (384 mg; 588.1 μmol; 46 %) as colorless crystals. M.p.: 291 °C; ¹H NMR (300 MHz, C₆D₆): δ [ppm] = 8.01 (d, ⁴J_{HH} = 1.1 Hz, H1^A, 1H), 7.53 (d, ³J_{HH} = 1.5 Hz, H3, 1H), 6.78 (d, ⁴J_{HH} = 1.1 Hz, H2^A, 1H), 6.69 (d, ⁴J_{HH} = 0.6 Hz, m-Mes^{NHC}, 2H), 6.56 (d, ⁴J_{HH} = 0.6 Hz, m-Mes^{aNHC}, 2H), 6.36 (d, ³J_{HH} = 1.5 Hz, H2, 1H), 2.04 (s, p-CH₃(Mes^{NHC}), 3H), 2.02 (s, p-CH₃(Mes^{aNHC}), o-CH₃(Mes^{NHC}), 9H), 1.75 (s, o-CH₃(Mes^{aNHC}), 6H), 1.35 (s, tBu^A, 18H), 1.02 (s, tBu^B, 18H); ¹³C{¹H} NMR (75 MHz, C₆D₆): δ [ppm] = 169.8 (C1), 150.8 (C3^A), 139.9 (C1^A), 139.4 (i-Mes^{NHC}), 139.3 (i-Mes^{aNHC}), 136.5 (o-Mes^{NHC}), 136.4 (p-Mes^{NHC}), 135.1 (o-Mes^{aNHC}), 132.9 (p-Mes^{aNHC}), 129.5 (m-Mes^{NHC}), 129.3 (m-Mes^{aNHC}), 129.1 (C2^A), 128.0 (C3), 123.7 (C2), 31.9 (C(CH₃)₃-tBu^B), 31.8 (C(CH₃)₃-tBu^A), 20.9 (p-CH₃(Mes^{aNHC})), 20.8 (p-CH₃(Mes^{NHC})), 18.7 (o-CH₃(Mes^{NHC})), 17.0 (o-CH₃(Mes^{aNHC})), 15.5 (C(CH₃)₃-tBu^B), 15.1 (C(CH₃)₃-tBu^A); ¹⁵N NMR (30 MHz, C₆D₆): δ [ppm] = 224.1 (s, N^{Al(NHC)}), 218.5 (s, N^{Al(aNHC)}), 196.3 (s, N^{Mes(NHC)}), 182.0 (s, N^{Mes(aNHC)}); IR (ATR; cm⁻¹): ̄ = 3134 (vw), 2936 (w), 2920 (w), 2864 (w), 2819 (s), 2753 (vw), 2691 (vw), 1734 (vw), 1609 (vw), 1542 (vw), 1523 (w), 1486 (w), 1464 (m), 1383 (w), 1354 (vw), 1277 (vw), 1239 (w), 1217 (vw), 1180 (vw), 1114 (m), 1086 (w), 1034 (vw), 1003 (w), 981 (w), 955 (vw), 935 (vw), 853 (m), 835 (w), 810 (s), 769 (vw), 750 (w), 703 (vw), 669 (w), 615 (w), 578 (s), 540 (m), 490 (vs), 464 (m), 449 (m), 426 (s), 413 (m); HRMS (EI): m/z calcd. for [C₃₆H₅₃Al₂N₄]: 595.3901 [M-C₄H₉]; found 595.3104 [M-C₄H₉], 539.2395 [M-2C₄H₉]; elemental analysis calcd. Synthesis of 10: $Na[N(SiMe_3)_2]$ (177 mg; 965.7 μmol; 1.0 equiv.) was dissolved in 10 mL of THF and cooled to 0 °C. At this temperature a solution of **8** (392 mg; 964.6 μmol; 1.0 equiv.) in 10 mL of THF, cooled to 0 °C, was added slowly. After 2 h stirring the solvent was removed at 0 °C under reduced pressure. The residue was suspended in 10 mL of pentane, filtered and the filtrate was stored at 4 °C for crystallization. After removal of the supernatant **10** (128 mg; 229.0 μmol; 24 %) was isolated as yellow powder. M.p.: 38 °C (decomposition); 1H NMR (300 MHz, C_6D_6): δ [ppm] = 7.49 (dd, $^3J_{HH}$ = 7.4 Hz, $^4J_{HH}$ = 1.5 Hz, H4, 1H), 7.04 (ddd, $^3J_{HH}$ = 7.9 Hz, $^4J_{HH}$ = 7.4 Hz, $^4J_{HH}$ = 1.4 Hz, H6, 1H), 6.72 (td, $^3J_{HH}$ = 7.3 Hz, $^4J_{HH}$ = 1.1 Hz, H5, 1H), 6.44 (dd, $^3J_{HH}$ = 7.9 Hz, $^4J_{HH}$ = 1.1 Hz, H7, 1H), 5.11 (s, C1H, 1H), 3.59–3.51 (m, 1,4-THF, 4H), 2.45–1.55 (m, Cy, 10H), 1.40 (s, tBu^A, 9H), 1.25 (s, tBu^B, 9H), 0.90–0.85 (m, 2,3-THF, 4H), 0.51 (s, TMS^A, 9H), 0.19 (s, TMS^B, 9H); $^{13}C\{^1H\}$ NMR (75 MHz, C_6D_6): δ [ppm] = 157.2 (C8), 137.4 (C3), 126.8 (C6), 126.1 (C4), 115.4 (C5), 111.2 (C7), 88.4 (C1), 73.1 (1,4-THF), 51.3 (C2), 39.3 (Cy), 32.8 ($C(CH_3)_3$, tBu^B), 32.2 ($C(CH_3)_3$, tBu^A), 31.2 (Cy), 26.6 (Cy), 24.8 (2,3-THF), 24.0 (Cy), 22.8 (Cy), 17.3 ($C(CH_3)_3$, tBu^B), 15.7 ($C(CH_3)_3$, tBu^A), 6.3 (TMS^B), 5.6 (TMS^A); ^{15}N NMR (30 MHz, C_6D_6): δ [ppm] = 102.3 (N^A), 48.4 (N^{(N(SiMe_3)_2)}); ^{29}Si NMR (60 MHz, C_6D_6): δ [ppm] = 6.70 (Si^{TMSA}), -2.71 (Si^{TMSB}); IR (ATR; cm⁻¹): ν = 2928 (w), 2863 (vw), 1592 (vw), 1557 (vw), 1464 (w), 1450 (w), 1380 (vw), 1356 (vw), 1327 (vw), 1281 (vw), 1249 (m), 1213 (w), 1182 (vw), 1037 (w), 1023 (vw), 989 (m), 961 (w), 927 (w), 905 (m),

887 (s), 861 (w), 831 (vs), 810 (s), 768 (m), 750 (s), 739 (s), 672 (w), 638 (vw), 623 (vw), 608 (vw), 575 (m), 558 (w), 544 (vw), 505 (vw), 457 (w), 438 (w), 417 (s); HRMS (El): m/z calcd. for $[C_{31}H_{58}AlN_2OSi_2]$: 557.3903 [M – H]; found 557.3625 [M – H]; elemental analysis calcd. (%) for $[C_{31}H_{59}N_2AlOSi_2]$: C 66.61, H 10.64, N 5.01, Al 4.83, O 2.86, Si 10.05; found C 65.84, H 10.110, N 4.80.

CCDC 1980987 (for **1**), 1980936 (for **2**), 1980933 (for **2^aNHC**), 1980934 (for **5**), 1980986 (for **6**), 1980935 (for **7**), 1980988 (for **8**), and 1980937 (for **10**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre.

Acknowledgments

We thank Manuel Link for preparative work on the spiroindole derivatives.
