(Received 8 July 2015; published 8 October 2015)

We study $SU(3)$ flavor-breaking corrections to the relation between the octet baryon masses and the nucleon-meson CP -violating interactions induced by the QCD $\bar{\theta}$ term. We work within the framework of $SU(3)$ chiral perturbation theory and work through next-to-next-to-leading order in the $SU(3)$ chiral expansion, which is $\mathcal{O}(m_q^2)$. At lowest order, the CP -odd couplings induced by the QCD $\bar{\theta}$ term are determined by mass splittings of the baryon octet, the classic result of Crewther *et al.* [*Phys. Lett. B* **88**, 123 (1979)]. We show that for each isospin-invariant CP -violating nucleon-meson interaction there exists one relation that is respected by loop corrections up to the order we work, while other leading-order relations are violated. With these relations we extract a precise value of the pion-nucleon coupling \bar{g}_0 by using recent lattice QCD evaluations of the proton-neutron mass splitting. In addition, we derive semiprecise values for CP -violating coupling constants between heavier mesons and nucleons with $\sim 30\%$ uncertainty and discuss their phenomenological impact on electric dipole moments of nucleons and nuclei.

I. INTRODUCTION

Violation of time reversal (T), or, equivalently, violation of the product of charge conjugation and parity (CP) is one of the ingredients [1] needed to explain the matter-antimatter asymmetry of the visible universe. The standard model (SM) of particle physics contains two sources of CP violation, the phase of the Cabibbo-Kobayashi-Maskawa (CKM) matrix and the QCD $\bar{\theta}$ term. The phase of the CKM matrix explains the observed CP violation in K and B decays [2], but appears to be too small for electroweak baryogenesis (see Ref. [3] and references therein). The QCD $\bar{\theta}$ term is severely constrained by the nonobservation of the neutron electric dipole moment (EDM). The current limit on the neutron EDM, $|d_n| < 2.9 \times 10^{-13} e \text{ fm}$ [4], bounds $\bar{\theta}$ to be small, $\bar{\theta} < 10^{-10}$, the well-known strong CP problem.

The viability of attractive, low-scale baryogenesis mechanisms such as electroweak baryogenesis thus requires new sources of CP violation. With the assumption that new physics is heavier than the electroweak scale and that there are no new light degrees of freedom, new sources of CP violation appear as higher-dimensional operators in the SM Lagrangian, suppressed by powers of the scale M_χ at which T violation arises. These operators involve SM particles and respect the SM gauge symmetry. In the quark sector, they are at least dimension six and are suppressed by two powers of M_χ [5,6]. EDMs of the nucleon, light-nuclei, atomic, and molecular systems are extremely sensitive probes of such flavor-diagonal T -violating (\mathcal{X}) operators; for reviews, see Refs. [7–9]. The current generation of experiments probes scales of TeV (or higher) and provides powerful constraints on new physics models, complementary to direct searches of new physics at colliders. Furthermore, a vigorous experimental program is under way [10] to improve current bounds on the neutron EDM [4] by two orders of magnitude, to measure EDMs of

light nuclei at the same or even higher level of accuracy [11,12] and to improve the bounds on EDMs of diamagnetic atoms, like ^{199}Hg [13], ^{129}Xe [14], and ^{225}Ra [15].

The extraction of robust information on possible new sources of CP violation from EDM measurements involves dynamics on a large variety of scales, from the new physics scale M_χ to the electroweak (EW) and QCD scales, down to the atomic scale. The step to hadronic and nuclear scales involves nonperturbative strong matrix elements, which are often poorly known, leading to large uncertainties [8]. In recent years, lattice QCD has made progress in computing the nucleon EDM induced by the QCD $\bar{\theta}$ term [16–18], while the study of the nucleon EDM generated by higher-dimensional operators is still in its infancy (an exception is the quark EDM [19]). Another important ingredient for the study of EDMs is composed of \mathcal{X} pion-nucleon couplings, which determine the leading nonanalytic contribution to the nucleon EDM [20]. In addition, they generate \mathcal{X} long-range nucleon-nucleon potentials, contributing to EDMs of light nuclei [21,22], and diamagnetic atoms [7,8].

The direct calculation of \mathcal{X} pion-nucleon couplings on the lattice, from both $\bar{\theta}$ and dimension-six operators, is difficult. Some information can be gained by the study of the momentum dependence of the electric dipole form factor (EDFF) [23,24], but the most recent lattice calculations are performed at too-large momenta for a reliable extraction [16,18,25]. Fortunately, in some cases other methods exist to extract the values of the pion-nucleon interactions. For chiral-symmetry-breaking sources, like the QCD $\bar{\theta}$ term, or the light-quark chromoelectric dipole moments (qCEDMs), the pion-nucleon couplings are intimately related to CP -even, chiral-symmetry-breaking effects. In the case of the QCD $\bar{\theta}$ term this was realized in Ref. [20], which expressed the isoscalar \mathcal{X} coupling \bar{g}_0 in terms of mass splittings of the octet baryons. In particular,

in SU(2) chiral perturbation theory (χ PT) it is possible to relate \bar{g}_0 to the neutron-proton mass difference induced by the quark mass difference $m_d - m_u$, which we denote by δm_N . All the information on nonperturbative dynamics entering \bar{g}_0 can thus be extracted by computing a property of the baryon spectrum, the nucleon mass splitting, a task for which lattice QCD is particularly well suited. Indeed, existing calculations of the nucleon mass splitting allow a determination of \bar{g}_0 with 10% accuracy [26,27], if one considers only lattice uncertainties. Similar relations between \mathcal{X} pion-nucleon couplings and modifications to the meson and baryon spectrum can be derived in the case of the qCEDM operators [7,28] and provide a viable route to improve the determination of couplings that, at the moment, are only known at the order-of-magnitude level [7,8,29].

The relations between \mathcal{X} couplings and baryon masses strictly hold at leading order (LO) in χ PT. Furthermore, if one considers the strange quark as light and extends the chiral group to SU(3) \times SU(3), more LO relations can be written; e.g., \bar{g}_0 can be expressed in terms of the mass difference of the Ξ and Σ baryons. Using the two LO relations leads to values of \bar{g}_0 that differ by about 50%, well beyond the lattice QCD uncertainty. Is this large difference owing to an inherent uncertainty in the relation between the spectrum and the \mathcal{X} couplings? Does this imply that the relations to the baryon spectrum can only be used for order-of-magnitude estimates of the \mathcal{X} couplings?

In this paper we investigate these questions and seek to quantify the SU(3) flavor-breaking corrections between the baryon masses and \mathcal{X} couplings induced by the QCD $\bar{\theta}$ term. We work in the framework of SU(3) heavy-baryon χ PT [30,31] and compute higher-order corrections in the chiral expansion. We show that most LO relations are badly violated, already at next-to-leading order (NLO) and cannot be used for reliable extractions of the meson-nucleon couplings. However, for all isospin-invariant \mathcal{X} couplings there exists exactly one relation that is preserved by all loop corrections up to next-to-next-to-leading order (N²LO). By using the relations that are not violated by SU(3) flavor breaking, a precise extraction of the couplings is possible irrespective of the convergence of SU(3) χ PT through this order. In the case of \bar{g}_0 , the preserved relation is to δm_N , while the relation to the mass difference of the Ξ and Σ baryons receives large NLO and N²LO corrections, which show little sign of convergence. Expressing \bar{g}_0 in terms of the Ξ and Σ masses overestimates the coupling by about 50%, well outside the uncertainty which is determined with δm_N .

For isospin-breaking couplings, such as the isovector pion-nucleon coupling \bar{g}_1 , we were not able to identify any robust relation that does not receive large violations already at NLO. We are forced to conclude that SU(3) heavy-baryon χ PT does not provide a reliable method to extract this important coupling from known matrix elements.

In this work we focus only on CP violation from the SM QCD $\bar{\theta}$ term, leaving higher-dimensional operators arising from possible beyond-standard-model (BSM) physics for future work. However, our results are also relevant for scenarios of BSM physics where the strong CP problem is solved by a Peccei-Quinn mechanism. In this case, an effective $\bar{\theta}$ term can

be induced proportional to any appearing higher-dimensional CP -odd sources [7,32]. Other BSM scenarios involve cases where parity is assumed to be an exact symmetry at high energies, requiring $\bar{\theta} = 0$ [33], while a calculable contribution to $\bar{\theta}$ is induced at lower energies once parity is spontaneously broken; see, for instance, Ref. [34]. In any case, a quantitative understanding of the low-energy consequences of the $\bar{\theta}$ term is necessary to unravel the underlying source of CP violation once a nonzero EDM is measured [35] and to test scenarios, such as the one in Ref. [36], where a small but nonzero $\bar{\theta}$ term is expected. Our values of the CP -odd pion-nucleon couplings can also be used for more precise limits on axion searches [37,38].

This paper is organized as follows. In Sec. II we review the closely related chiral-symmetry-breaking and \mathcal{X} sectors of the χ PT Lagrangian. In Sec. III we discuss baryon masses and \mathcal{X} couplings at tree level and identify the relations between masses and couplings imposed by SU(3) symmetry. In Sec. IV we study NLO corrections to masses and \mathcal{X} couplings and identify which relations are respected by NLO loop corrections. In Sec. V A we discuss in detail N²LO corrections to the nucleon mass splitting, including, for the first time, decuplet corrections. The expressions of N²LO corrections to the mass splittings of the Ξ and Σ baryons and to the octet baryon average masses are relegated to Appendixes A and B. In Sec. V B we examine N²LO corrections to \bar{g}_0 and show that all the loops at this order are related to contributions to the nucleon mass splitting. In Secs. V C and V D we discuss the remaining \mathcal{X} nucleon couplings. In Sec. VI we use the conserved relations to determine the value of the \mathcal{X} couplings induced by the QCD $\bar{\theta}$ term and discuss the impact of our analysis on the nucleon EDF and on the \mathcal{X} nucleon-nucleon potential. We conclude in Sec. VII.

II. QCD AND EFT LAGRANGIAN

At the QCD scale, $\mu \sim 1$ GeV, heavy gauge bosons, the Higgs and the heavy quarks can be integrated out, and the SM Lagrangian involves gluons, photons, and three flavors of quarks,

$$\begin{aligned} \mathcal{L}_{\text{QCD}} = & -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - \frac{1}{4}G_{\mu\nu}^a G^{a\mu\nu} + \bar{q}i \not{D}q - e^{i\rho} \bar{q}_L \mathcal{M} q_R \\ & - e^{-i\rho} \bar{q}_R \mathcal{M} q_L - \theta \frac{g_s^2}{64\pi^2} \varepsilon^{\mu\nu\alpha\beta} G_{\mu\nu}^a G_{\alpha\beta}^a, \end{aligned} \quad (1)$$

where q is a triplet of quark fields $q = (u, d, s)$, $F_{\mu\nu}$ and $G_{\mu\nu}^a$ are the photon and gluon field strengths, and D_μ is the SU(3)_c \times U(1)_{em} covariant derivative. The first three terms in Eq. (1) are the photon, gluon, and quark kinetic terms. Without loss of generality, the quark mass matrix can be expressed in terms of a real diagonal matrix $\mathcal{M} = \text{diag}(m_u, m_d, m_s)$, and a common phase ρ . The last term in Eq. (1) is the QCD $\bar{\theta}$ term. Despite being a total derivative, it contributes to physical observables through extended field configurations, the instantons [39]. The two CP -violating parameters in Eq. (1), θ and the phase ρ , are not independent, and CP violation is proportional to the combination $\bar{\theta} = \theta - n_f \rho$, where $n_f = 3$ is the number of flavors of light quarks. This can be explicitly seen by performing an anomalous $U_A(1)$ axial

rotation. With an appropriate choice of phase, the θ term can be completely eliminated, in favor of a complex mass term. The residual freedom of performing nonanomalous $SU(3)_A$ axial rotations can be used to align the vacuum in presence of CP violation to the original vacuum of the theory. If the complex mass term is the only \mathcal{F} operator in the theory, vacuum alignment is accomplished by making the complex mass term isoscalar [40]. At the level of the meson Lagrangian, the condition of vacuum alignment is equivalent to setting the LO coupling of the pion and η meson to the vacuum to zero.

After vacuum alignment, the QCD Lagrangian in the presence of the $\bar{\theta}$ term reads

$$\mathcal{L}_{\text{QCD}} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - \frac{1}{4}G_{\mu\nu}^a G^{a\mu\nu} + \bar{q}i\not{D}q - \bar{q}(\mathcal{M} - i\gamma_5 m_*\bar{\theta})q, \quad (2)$$

where we denote

$$m_* = \frac{m_u m_d m_s}{m_s(m_u + m_d) + m_u m_d} = \frac{\bar{m}(1 - \varepsilon^2)}{2 + \frac{\bar{m}}{m_s}(1 - \varepsilon^2)}, \quad (3)$$

with $2\bar{m} = m_u + m_d$ and $\varepsilon = (m_d - m_u)/(m_d + m_u)$. When providing numerical results, we take the values of these quantities from the most recent lattice average by Flavor Lattice Averaging Group (FLAG) (quoted in the $\overline{\text{MS}}$ scheme at $\mu = 2$ GeV when relevant) [41]:

$$\begin{aligned} \bar{m} &= 3.42 \pm 0.09 \text{ MeV}, & \frac{m_s}{\bar{m}} &= 27.46 \pm 0.44, \\ \varepsilon &= 0.37 \pm 0.03. \end{aligned} \quad (4)$$

The QCD Lagrangian is approximately invariant under the global chiral group $SU(3)_L \times SU(3)_R$. Chiral symmetry and its spontaneous breaking to the vector subgroup $SU(3)_V$ lead to the emergence of an octet of pseudo-Nambu-Goldstone (pNG) bosons, the pion, kaon, and η mesons, whose interactions are dictated by chiral symmetry. The quark mass and the QCD $\bar{\theta}$ term break chiral symmetry explicitly. Chiral invariance can be formally recovered by assigning the mass term the transformation properties

$$\begin{aligned} \mathcal{M} + im_*\bar{\theta} &\rightarrow R(\mathcal{M} + im_*\bar{\theta})L^\dagger, \\ \mathcal{M} - im_*\bar{\theta} &\rightarrow L(\mathcal{M} - im_*\bar{\theta})R^\dagger, \end{aligned} \quad (5)$$

under a $SU(3)_L \times SU(3)_R$ rotation. The QCD $\bar{\theta}$ term thus induces \mathcal{F} interactions between pNG bosons, and pNG bosons and matter fields, that can be constructed using the same spurion fields employed in the construction of the meson and baryon mass terms. We refer to Refs. [20,28,42–45] for more details. In the next sections we give the meson and baryon χ PT Lagrangians relevant to the calculation of \mathcal{F} baryon-pNG couplings at $N^2\text{LO}$.

A. Meson sector

The constraints imposed by chiral symmetry and its spontaneous and explicit breaking on the interactions of pNG bosons can be formulated in an effective Lagrangian, χ PT [42,46–49], whose construction is well known. We adopt here the notation of Ref. [42]. In the absence of explicit chiral symmetry breaking, the interactions of pNG bosons are proportional to their momentum, q , which guarantees that low-momentum

observables can be computed as a perturbative expansion in q/Λ_χ , where Λ_χ is a typical hadronic scale, $\Lambda_\chi \sim 1$ GeV. The quark masses explicitly break chiral symmetry, giving masses to the pNG bosons and inducing nonderivative couplings. However, the breaking is small and can be incorporated in the expansion by counting each insertion of the quark mass as q^2 .

We assign each term in the χ PT Lagrangian an integer index that counts the powers of momentum or of the quark mass. The LO meson Lagrangian contains two derivatives or one light-quark mass insertion and is given by

$$\mathcal{L}_\pi^{(2)} = \frac{F_0^2}{4}\text{Tr}(\partial_\mu U \partial^\mu U^\dagger) + \frac{F_0^2}{4}\text{Tr}[U^\dagger \chi + U \chi^\dagger], \quad (6)$$

where F_0 is the pion decay constant in the chiral limit. Beyond LO, $SU(3)$ breaking corrections break the degeneracy of the pion, kaon, and η decay constants. We denote by F_π and F_K the empirical pion and kaon decay constants, $F_\pi = 92.2$ MeV and $F_K = 113$ MeV [2]. F_η can be expressed in terms of F_K and F_π , and we use $F_\eta = 1.3 F_\pi$ [42]. In Eq. (6) we introduced the unitary matrix

$$U(\pi) = u(\pi)^2 = \exp\left(\frac{2i\pi}{F_0}\right), \quad (7)$$

where π 's are the pNG boson fields,

$$\pi = \pi^a t_{ij}^a = \frac{1}{\sqrt{2}} \begin{pmatrix} \frac{\pi_3}{\sqrt{2}} + \frac{\pi_8}{\sqrt{6}} & \pi^+ & K^+ \\ \pi^- & -\frac{\pi_3}{\sqrt{2}} + \frac{\pi_8}{\sqrt{6}} & K^0 \\ K^- & \bar{K}^0 & -\frac{2}{\sqrt{6}}\pi_8 \end{pmatrix}, \quad (8)$$

where $(t^a)_{ij}$ are the generators of $SU(3)$, $a = 1, \dots, 8$ is the octet index, and $i, j = 1, \dots, 3$ are indices of the fundamental representation of $SU(3)$. Under a $SU(3)_L \times SU(3)_R$ transformation, the pNG field has a complicated nonlinear transformation, while U transforms simply as $U \rightarrow RUL^\dagger$. The first term in Eq. (6) is chirally invariant. The second term, with $\chi = 2B(\mathcal{M} + im_*\bar{\theta})$, is the realization of the quark mass term which, with the transformation properties in Eq. (5), is also formally invariant.

Equation (6) induces the leading contribution to the pion, kaon, and η meson masses,

$$\begin{aligned} m_{\pi^\pm}^2 &= 2B\bar{m}, \\ m_{\pi^0}^2 &= 2B\bar{m} - B\frac{\bar{m}^2\varepsilon^2}{m_s - \bar{m}}, \\ m_\eta^2 &= \frac{2}{3}B(2m_s + \bar{m}) + B\frac{\bar{m}^2\varepsilon^2}{m_s - \bar{m}}, \\ m_{K^\pm}^2 &= B(m_s + \bar{m} - \bar{m}\varepsilon), \\ m_{K^0}^2 &= B(m_s + \bar{m} + \bar{m}\varepsilon). \end{aligned} \quad (9)$$

When working in the isospin limit, we denote $m_K^2 = B(m_s + \bar{m})$. At the order we are working, we need the meson masses only at LO, and, for numerical evaluations, we use the Particle Data Group (PDG) values $m_{\pi^\pm} = 139.6$ MeV, $m_{K^+} = 493.7$ MeV, $m_{K^0} = 497.6$ MeV, $m_\eta = 547.9$ MeV [2]. The experimental error on the meson masses is always negligible compared to other uncertainties in the calculations, and we can neglect it.

The relation between the physical π_0 and η and the pNG bosons π_3 and π_8 is determined, at LO, by the π - η mixing angle ϕ ,

$$\begin{aligned}\pi_0 &= \cos \phi \pi_3 + \sin \phi \pi_8, \\ \eta &= -\sin \phi \pi_3 + \cos \phi \pi_8,\end{aligned}\quad (10)$$

with

$$\frac{\phi}{\sqrt{3}} = \frac{\bar{m}\varepsilon}{2(m_s - \bar{m})}.\quad (11)$$

Beyond lowest order, η - π mixing cannot simply be described by a mixing angle [42,50].

In the \mathcal{X} sector, vacuum alignment eliminates pion and η tadpoles in LO. In SU(2) χ PT, vacuum alignment eliminates all LO three-pion vertices. However, in SU(3) χ PT the meson mass term induces a three-pNG vertex of the form

$$\mathcal{L}_{\pi\pi\pi} = -\frac{B}{3F_0} m_s \bar{\theta} d^{abc} \pi_a \pi_b \pi_c, \quad (12)$$

where d^{abc} are the constants determined by the anticommutator of SU(3) generators

$$\{t^a, t^b\} = \frac{1}{3} \delta^{ab} + d^{abc} t^c. \quad (13)$$

The interaction in Eq. (12) involves one η and two pions, one η and two kaons, or one pion and two kaons and induces the CP -odd decay $\eta \rightarrow \pi\pi$. Limits on this branching ratio make it possible to put a bound on $\bar{\theta}$, though several orders of magnitude less stringent than the bound from the neutron EDM [51]. Three-pion interactions also arise at LO, but they are proportional to the η - π mixing angle and vanish for large m_s .

The $\mathcal{O}(q^4)$ meson Lagrangian is well known [42]. At the order we are working, we only need the terms

$$\begin{aligned}\mathcal{L}_\pi^{(4)} \supset & L_4 \text{Tr}(\partial_\mu U^\dagger \partial^\mu U) \text{Tr}(\chi^\dagger U + U^\dagger \chi) \\ & + L_5 \text{Tr}[\partial_\mu U^\dagger \partial^\mu U (\chi^\dagger U + U^\dagger \chi)] \\ & + L_7 [\text{Tr}(U \chi^\dagger - \chi U^\dagger)]^2 \\ & + L_8 \text{Tr}(U \chi^\dagger U \chi^\dagger + \chi U^\dagger \chi U^\dagger).\end{aligned}\quad (14)$$

L_4 and L_5 contribute to the pNG wave function renormalization and to the renormalization of F_0 . L_7 and L_8 generate pion and η tadpoles, which contribute to \mathcal{X} pion-nucleon couplings at N²LO. For \mathcal{X} baryon-pNG couplings, the dependence on L_4 and L_5 cancels between the wave function renormalization and the corrections to F_0 . L_7 and L_8 have been determined from global fits to meson data [52,53]. We use the NLO fits in Ref. [53], which give $L_7 = (-0.3 \pm 0.2) \times 10^{-3}$ and $L_8 = (0.5 \pm 0.2) \times 10^{-3}$. L_8 is scale dependent, and it is evaluated at the scale $\mu = 770$ MeV.

B. Baryon sector

The inclusion of baryons in χ PT has been derived in a large number of papers, for instance Refs. [30,31,54–57]. The baryon octet can be included in a way consistent with the chiral expansion by working in the nonrelativistic limit and removing the large, inert octet mass m_B [30,31]. The mass splittings of octet states vanish in the chiral limit and scale as $\mathcal{O}(q^2)$.

χ PT can be extended to include the decuplet baryons at the price of introducing a new scale Δ , the decuplet-octet splitting, which does not vanish in the chiral limit, nor can it be rotated away [30,57]. This octet-decuplet splitting scales as $1/N_c$ in the large N_c expansion [58–60]. The explicit inclusion of the decuplet is necessary for the chiral expansion to respect the $1/N_c$ counting rules [61], and the predictions from a combined SU(3)- $1/N_c$ expansion are phenomenologically well satisfied in lattice QCD calculations [62,63].

In the heavy-baryon formalism, the lowest-order chiral-invariant octet and decuplet baryon Lagrangian is given by

$$\begin{aligned}\mathcal{L}^{(1)} &= \text{Tr}(i \bar{B} v \cdot \mathcal{D} B) + F \text{Tr}(\bar{B} S_\mu [u^\mu, B]) \\ &+ D \text{Tr}(\bar{B} S_\mu \{u^\mu, B\}) - i \bar{T}^\mu v \cdot \mathcal{D} T_\mu + \Delta \bar{T}^\mu T_\mu \\ &+ \frac{\mathcal{C}}{2} (\bar{T}^\mu u_\mu B + \bar{B} u_\mu T^\mu) + \mathcal{H} \bar{T}^\mu S^v u_\nu T_\mu,\end{aligned}\quad (15)$$

where v_μ and S_μ denote the heavy-baryon velocity and spin. D and F are the octet axial couplings, $D \simeq 0.8$ and $F \simeq 0.45$, and $D + F = g_A = 1.27$. \mathcal{C} is the decuplet-octet axial coupling, $\mathcal{C} \simeq 1.5$. \mathcal{H} is the decuplet axial coupling, which does not play a role in our discussion. The matrix B denotes the octet baryon field

$$B = B^a t_{ij}^a = \begin{pmatrix} \frac{1}{\sqrt{2}} \Sigma^0 + \frac{1}{\sqrt{6}} \Lambda & \Sigma^+ & p \\ \Sigma^- & -\frac{1}{\sqrt{2}} \Sigma^0 + \frac{1}{\sqrt{6}} \Lambda & n \\ \Xi^- & \Xi^0 & -\frac{2}{\sqrt{6}} \Lambda \end{pmatrix}.\quad (16)$$

The decuplet field T_{ijk}^μ carries three completely symmetrized fundamental indices. The pNG bosons appear through the combinations $u_\mu = u^\dagger i \partial_\mu u - u i \partial_\mu u^\dagger$ and, in the covariant derivatives, $V_\mu = \frac{1}{2}(u \partial_\mu u^\dagger + u^\dagger \partial_\mu u)$. The chiral covariant derivatives are

$$\mathcal{D}_\mu B = \partial_\mu B + [V_\mu, B], \quad (17)$$

$$\mathcal{D}_\nu T_{ijk}^\mu = \partial_\nu T_{ijk}^\mu + (V_\nu)_{il} T_{ijk}^\mu + (V_\nu)_{jl} T_{ilk}^\mu + (V_\nu)_{kl} T_{ijl}^\mu. \quad (18)$$

Invariant terms involving the octet and decuplet baryons are constructed using the contractions

$$\bar{B} u_\mu T^\mu \equiv \bar{B}_{il} u_{\mu j m} T_{klm}^\mu \varepsilon^{ijk}, \quad \bar{T}^\mu u_\mu B \equiv \bar{T}_{klm}^\mu u_{\mu m j} B_{li} \varepsilon^{ijk}.\quad (19)$$

Baryon mass terms and \mathcal{X} couplings appear in the SU(3) Lagrangian at $\mathcal{O}(q^2)$, and they are given by [30]

$$\begin{aligned}\mathcal{L}^{(2)} &= b_0 \text{Tr}(\bar{B} B) \text{Tr} \chi_+ + b_D \text{Tr}(\bar{B} \{\chi_+, B\}) + b_F \text{Tr}(\bar{B} [\chi_+, B]) \\ &+ b_C \bar{T}^\mu \chi_+ T_\mu + b_\Delta \text{Tr}(\chi U^\dagger + \chi^\dagger U) \bar{T}^\mu T_\mu,\end{aligned}\quad (20)$$

where $\chi_+ = u^\dagger \chi u^\dagger + u \chi^\dagger u$. b_0 and b_Δ denote common shifts to all octet and decuplet masses, and do not give rise to \mathcal{X} nucleon couplings with one pNG boson. b_D , b_F , and b_C induce splittings between the different octet and decuplet states and give rise to \mathcal{X} baryon-pNG interactions. The low energy constant (LECs) b_0 , b_D , and b_F scale as Λ_χ^{-1} , and do not depend on the quark masses. When including decuplet corrections b_0 , b_D , and b_F must be interpreted as series expansions in the

octet-decuplet splitting Δ [64–67]

$$b_i = \frac{1}{\Lambda_\chi} \left(b_i^{(0)} + b_i^{(1)} \frac{\Delta}{\Lambda_\chi} + b_i^{(2)} \frac{\Delta^2}{\Lambda_\chi^2} + \dots \right), \quad (21)$$

where the higher orders in Δ/Λ_χ arise from finite contributions and are needed to absorb the divergences arising from diagrams with decuplet intermediate states. There is no sense in keeping track of the finite Δ dependence in the LECs as these corrections are quark mass independent, and thus not discernible with present lattice QCD calculations at fixed $N_c = 3$.

Baryon mass splittings and \mathcal{X} couplings receive $\mathcal{O}(q^3)$ corrections from one-loop diagrams involving the chiral-invariant interactions in Eq. (15), and chiral-breaking interactions from Eq. (6). This is distinct from $SU(2)$ χ PT in which the $\mathcal{O}(q^3)$ corrections cancel in the isospin mass splitting. At $\mathcal{O}(q^4)$, one

has to consider one-loop diagrams involving operators in the $\mathcal{O}(q^2)$ Lagrangian and tree-level diagrams with one insertion of the $\mathcal{O}(q^4)$ Lagrangian. Besides the mass terms in Eq. (20), $\mathcal{L}^{(2)}$ contains relativistic corrections to the interactions in Eq. (15), and baryon-pNG interactions with two derivatives. The operators are listed in Ref. [68] and here we give only those relevant to our discussion. There are four operators containing two derivatives of pNG fields:

$$\begin{aligned} \mathcal{L}_{\pi\pi}^{(2)} = & b_1 \text{Tr}(\bar{B}[u_\mu, \{u^\mu, B\}]) + b_2 \text{Tr}(\bar{B}[u_\mu, \{u^\mu, B\}]) \\ & + b_3 \text{Tr}(\bar{B}\{u_\mu, \{u^\mu, B\}\}) + b_8 \text{Tr}[\bar{B}B] \text{Tr}[u_\mu u^\mu]. \end{aligned} \quad (22)$$

The effects on the baryon masses of operators similar to b_1, \dots, b_8 , but with u_μ replaced with $v \cdot u$, can be accounted for by a redefinition of b_i and of the $\mathcal{O}(q^4)$ LECs. For this reason, we do not include these operators explicitly. The relativistic corrections are

$$\begin{aligned} \mathcal{L}_{\text{rel}}^{(2)} = & -\frac{D}{2m_B} \text{Tr}(\bar{B}S_\mu[iD^\mu, \{v \cdot u, B\}]) - \frac{F}{2m_B} \text{Tr}(\bar{B}S_\mu[iD^\mu, [v \cdot u, B]]) \\ & - \frac{F}{2m_B} \text{Tr}(\bar{B}S_\mu[v \cdot u, [iD^\mu, B]]) - \frac{D}{2m_B} \text{Tr}(\bar{B}S_\mu\{v \cdot u, [iD^\mu, B\}]) \\ & + \frac{D^2 - 3F^2}{24m_B} \text{Tr}(\bar{B}[v \cdot u, [v \cdot u, B]]) - \frac{D^2}{12m_B} \text{Tr}(\bar{B}B) \text{Tr}(v \cdot u v \cdot u) \\ & - \frac{1}{2m_B} \text{Tr}(\bar{B}[D_\mu, [D^\mu, B]]) + \frac{1}{2m_B} \text{Tr}(\bar{B}[v \cdot D, [v \cdot D, B]]) \\ & - \frac{DF}{4m_B} \text{Tr}(\bar{B}[v \cdot u, \{v \cdot u, B\}]). \end{aligned} \quad (23)$$

We find that the contribution of recoil corrections to D and F to the baryon masses is small. The relativistic corrections to the octet-decuplet coupling \mathcal{C} can be removed using the LO equations of motion [65–67].

The $\mathcal{O}(q^4)$ Lagrangian is

$$\begin{aligned} \mathcal{L}^{(4)} = & d_1 \text{Tr}(\bar{B}[\chi_+, [\chi_+, B]]) + d_2 \text{Tr}(\bar{B}[\chi_+, \{\chi_+, B\}]) + d_3 \text{Tr}(\bar{B}\{\chi_+, \{\chi_+, B\}\}) \\ & + d_4 \text{Tr}(\bar{B}\chi_+) \text{Tr}(\chi_+ \bar{B}) + d_5 \text{Tr}(\bar{B}[\chi_+, B]) \text{Tr}(\chi_+) + d_6 \text{Tr}(\bar{B}\{\chi_+, B\}) \text{Tr}(\chi_+) \\ & + d_7 \text{Tr}(\bar{B}B) \text{Tr}(\chi_+) \text{Tr}(\chi_+) + d_8 \text{Tr}(\bar{B}B) \text{Tr}(\chi_+^2) + d_9 \text{Tr}(\bar{B}[\chi_-, [\chi_-, B]]) + d_{10} \text{Tr}(\bar{B}[\chi_-, \{\chi_-, B\}]) \\ & + d_{11} \text{Tr}(\bar{B}\{\chi_-, \{\chi_-, B\}\}) + d_{12} \text{Tr}(\bar{B}\chi_-) \text{Tr}(\chi_- B) + d_{13} \text{Tr}(\bar{B}[\chi_-, B]) \text{Tr}(\chi_-) + d_{14} \text{Tr}(\bar{B}\{\chi_-, B\}) \text{Tr}(\chi_-) \\ & + d_{15} \text{Tr}(\bar{B}B) \text{Tr}(\chi_-) \text{Tr}(\chi_-) + d_{16} \text{Tr}(\bar{B}B) \text{Tr}(\chi_-^2). \end{aligned} \quad (24)$$

d_1, \dots, d_8 were constructed in Ref. [68] and contribute to baryon masses and splittings. The operators d_9, \dots, d_{16} involve two insertions of $\chi_- = u^\dagger \chi u^\dagger - u \chi^\dagger u$. The CP -even parts of these operators do not contribute to baryon masses and mass splittings, but do contribute to pion-nucleon scattering. The CP -odd components give $\mathcal{O}(q^4)$ corrections to \mathcal{X} baryon-pNG couplings.

III. OCTET BARYON MASSES AND \mathcal{X} COUPLINGS AT TREE LEVEL

The Lagrangian (20) realizes the leading effects of the light-quark masses in the baryon sector. The light-quark masses induce splittings between the octet and decuplet states, and, in the presence of the QCD $\bar{\theta}$ term, cause the appearance of \mathcal{X} couplings between baryon and pNG bosons. The LO

corrections to the baryon masses are well known (see, for example, Refs. [69,70]), we give them here to make the connection with \mathcal{X} couplings explicit.

The nucleon, Ξ , and Σ mass splittings are given by

$$\begin{aligned} \delta^{(0)} m_N = m_n - m_p &= -8B\bar{m}\varepsilon(b_F + b_D), \\ \delta^{(0)} m_\Xi = m_{\Xi^-} - m_{\Xi^0} &= -8B\bar{m}\varepsilon(b_F - b_D), \\ \delta^{(0)} m_\Sigma = m_{\Sigma^+} - m_{\Sigma^-} &= 16B\bar{m}\varepsilon b_F, \end{aligned} \quad (25)$$

respectively, where we introduced the superscript (0) to denote that these are the leading contributions. The three mass splittings are not independent, but are related by the Coleman-Glashow relation [71]

$$\delta^{(0)} m_N + \delta^{(0)} m_\Xi + \delta^{(0)} m_\Sigma = 0. \quad (26)$$

Neglecting $\mathcal{O}(\varepsilon^2)$ corrections to the Σ^0 and Λ masses, the isospin-averaged masses of the nucleon, Ξ , Σ , and Λ , baryon are

$$\begin{aligned}\Delta^{(0)}m_N &= \frac{m_n + m_p}{2} - m_B \\ &= -4B[m_s(b_0 + b_D - b_F) + \bar{m}(2b_0 + b_D + b_F)], \\ \Delta^{(0)}m_\Xi &= \frac{m_{\Xi^-} + m_{\Xi^0}}{2} - m_B \\ &= -4B[m_s(b_0 + b_D + b_F) + \bar{m}(2b_0 + b_D - b_F)], \\ \Delta^{(0)}m_\Sigma &= \frac{m_{\Sigma^+} + m_{\Sigma^0} + m_{\Sigma^-}}{3} - m_B \\ &= -4B[(m_s + 2\bar{m})b_0 + 2\bar{m}b_D], \\ \Delta^{(0)}m_\Lambda &= m_\Lambda - m_B = -4B\left[(m_s + 2\bar{m})b_0 + \frac{2}{3}(\bar{m} + 2m_s)b_D\right],\end{aligned}\tag{27}$$

respectively, where all the masses are measured with respect to m_B , the common octet mass in the chiral limit. Finally, m_B gets a corrections proportional to $m_s + 2\bar{m}$,

$$\begin{aligned}\Delta^{(0)}m_B &= \frac{2\Delta^{(0)}m_N + 2\Delta^{(0)}m_\Xi + 3\Delta^{(0)}m_\Sigma + \Delta^{(0)}m_\Lambda}{8} \\ &= -4B(m_s + 2\bar{m})\left(b_0 + \frac{2}{3}b_D\right).\end{aligned}\tag{28}$$

In the presence of a $\bar{\theta}$ term, the operators in Eq. (20) induce \mathcal{X} baryon-pNG couplings. The couplings of the greatest phenomenological interest are pion-nucleon couplings. Besides giving a LO contribution to the nucleon EDM, the isoscalar nonderivative pion-nucleon coupling \bar{g}_0 induces a \mathcal{X} nucleon-nucleon potential, which is expected to give a sizable, when not dominant, contribution to EDMs of light nuclei with $N \neq Z$ [21,72,73]. Furthermore, EDMs of heavier systems, like ^{199}Hg , are commonly computed in terms of three nonderivative pion-nucleon couplings [8].

Introducing the nucleon doublet, $N = (pn)^T$, we write the \mathcal{X} pion-nucleon couplings as

$$\mathcal{L}_\pi = -\frac{\bar{g}_0}{2F_\pi}\bar{N}\boldsymbol{\tau}\cdot\boldsymbol{\pi}N - \frac{\bar{g}_1}{2F_\pi}\pi_0\bar{N}N - \frac{\bar{g}_2}{2F_\pi}\pi_0\bar{N}\boldsymbol{\tau}^3N + \dots,\tag{29}$$

where $\boldsymbol{\tau}$ are the Pauli matrices and \dots includes terms with more derivatives. Notice that we defined the couplings in terms of the physical pion decay constant F_π , rather than F_0 . The difference between F_π and F_0 is an $N^2\text{LO}$ correction.

At tree level, the \mathcal{X} pion-nucleon couplings are expressed in terms of the LECs b_D and b_F . b_0 does not generate tree-level \mathcal{X} couplings with only one pNG boson, but does induce couplings with at least three pNG, which are relevant at one loop. \bar{g}_0 , \bar{g}_1 , and \bar{g}_2 are given by

$$\bar{g}_0^{(0)} = -8B(b_D + b_F)m_*\bar{\theta},\tag{30}$$

$$\bar{g}_1^{(0)} = 8B(b_D - 3b_F)\frac{\phi}{\sqrt{3}}m_*\bar{\theta},\tag{31}$$

$$\bar{g}_2^{(0)} = 4B(b_D + b_F)\phi^2m_*\bar{\theta},\tag{32}$$

where ϕ is the η - π mixing angle defined in Eq. (11). From Eqs. (25) and (30), we see that \bar{g}_0 is related to the tree-level contribution to the nucleon mass splitting,

$$\bar{g}_0^{(0)} = \delta^{(0)}m_N\frac{m_*\bar{\theta}}{\bar{m}\varepsilon} = \delta^{(0)}m_N\frac{1 - \varepsilon^2}{2\varepsilon}\bar{\theta} + \mathcal{O}\left(\frac{\bar{m}}{m_s}\right).\tag{33}$$

For $m_s \gg \bar{m}$, this is the same relation that holds in $\text{SU}(2)$ [44]. In $\text{SU}(3)$ χPT , at tree level one can also write [20]

$$\bar{g}_0^{(0)} = (\Delta^{(0)}m_\Xi - \Delta^{(0)}m_\Sigma)\frac{2m_*}{m_s - \bar{m}}\bar{\theta}.\tag{34}$$

We show that both Eq. (33) and Eq. (34) are violated at $N^2\text{LO}$. However, Eq. (33) is violated only by finite terms and by new LECs appearing at $\mathcal{O}(q^4)$, while it is respected by all loop diagrams. However, Eq. (34) is already violated at NLO and receives much larger corrections.

An isoscalar operator like $\bar{\theta}$ can generate the isospin-breaking couplings \bar{g}_1 and \bar{g}_2 only in the presence of some source of isospin violation. In $\text{SU}(2)$ χPT this implies that \bar{g}_1 and \bar{g}_2 are suppressed and appear at $\mathcal{O}(q^4)$ and $\mathcal{O}(q^6)$, respectively. In $\text{SU}(3)$ χPT , the η - π mixing angle ϕ appears at LO, which means that $\bar{g}_{1,2}$ are formally LO as well. However, numerically they are suppressed by powers of $\bar{m}/m_s \sim 0.04$.

The coupling \bar{g}_1 is particularly important for EDMs of nuclei with $N = Z$ such as the deuteron. At LO, the combination of LECs $b_D - 3b_F$ can be expressed in terms of baryon-mass splittings as

$$\begin{aligned}\bar{g}_1^{(0)} &= -(\delta^{(0)}m_\Sigma - \delta^{(0)}m_\Xi)\frac{\phi}{\sqrt{3}}\frac{m_*}{\bar{m}\varepsilon}\bar{\theta} \\ &= -(\Delta^{(0)}m_N - \Delta^{(0)}m_B)\frac{\phi}{\sqrt{3}}\frac{6m_*}{(m_s - \bar{m})}\bar{\theta} \\ &= -\left[\left(\frac{d}{dm_s} - \frac{d}{2d\bar{m}}\right)\Delta^{(0)}m_N\right]\frac{\phi}{\sqrt{3}}4m_*\bar{\theta},\end{aligned}\tag{35}$$

where the masses and splittings are given in Eq. (27). Equations (31) and (35) were used in Ref. [74] to estimate \bar{g}_1 and its contribution to the deuteron EDM. Contributions to \bar{g}_1 that are not suppressed by \bar{m}/m_s only appear at $N^2\text{LO}$. However, as we discuss in Sec. VC, they can be as large as Eq. (35).

In the case of the QCD $\bar{\theta}$ term, the coupling \bar{g}_2 is suppressed by \bar{m}^2/m_s^2 , and because it is of little phenomenological consequence, we neglect \bar{g}_2 henceforth.

Nonanalytic LO contributions to the nucleon EDM in $\text{SU}(3)$ χPT involve other \mathcal{X} nucleon couplings [23]. Introducing the isospin doublet $K = (K^+, K^0)$, and an isospin triplet $\Sigma = (\Sigma^+, \Sigma^0, \Sigma^-)$, we can write the isospin-invariant \mathcal{X} couplings between the nucleon and η meson, and the nucleon, kaon, and Σ or Λ baryon as

$$\mathcal{L} = -\frac{\bar{g}_{0\eta}}{2F_\eta}\eta\bar{N}N - \frac{\bar{g}_{0N\Sigma K}}{2F_K}\bar{N}\boldsymbol{\tau}\cdot\boldsymbol{\Sigma}K - \frac{\bar{g}_{0N\Lambda K}}{2F_K}\bar{N}K\Lambda^0 + \text{H.c.}\tag{36}$$

Isospin-breaking couplings also arise at LO, but are suppressed by $\bar{m}\varepsilon/m_s$, and we neglect them in the following. At LO, the

couplings in Eq. (36) are given by

$$\bar{g}_{0\eta}^{(0)} = 8B \frac{b_D - 3b_F}{\sqrt{3}} m_* \bar{\theta}, \quad (37)$$

$$\bar{g}_{0N\Sigma K}^{(0)} = 8B(b_F - b_D) m_* \bar{\theta}, \quad (38)$$

$$\bar{g}_{0N\Lambda K}^{(0)} = 8B \frac{(b_D + 3b_F)}{\sqrt{3}} m_* \bar{\theta}. \quad (39)$$

These \mathcal{X} couplings can be expressed in terms of various combinations of baryon masses. We list some of them,

$$\begin{aligned} \sqrt{3}\bar{g}_{0\eta}^{(0)} &= -(\delta^{(0)}m_\Sigma - \delta^{(0)}m_\Xi) \frac{m_* \bar{\theta}}{\bar{m}\varepsilon} \\ &= -\left[\left(\frac{d}{dm_s} - \frac{d}{2d\bar{m}} \right) \Delta^{(0)} m_N \right] 4m_* \bar{\theta}, \end{aligned} \quad (40)$$

$$\begin{aligned} \bar{g}_{0N\Sigma K}^{(0)} &= -\delta^{(0)}m_\Xi \frac{m_* \bar{\theta}}{\bar{m}\varepsilon} \\ &= -(\Delta^{(0)}m_\Sigma - \Delta^{(0)}m_N) \frac{2m_* \bar{\theta}}{m_s - \bar{m}}, \end{aligned} \quad (41)$$

$$\begin{aligned} \sqrt{3}\bar{g}_{0N\Lambda K}^{(0)} &= -(\delta^{(0)}m_N - \delta^{(0)}m_\Sigma) \frac{m_* \bar{\theta}}{\bar{m}\varepsilon} \\ &= -(\Delta^{(0)}m_\Lambda - \Delta^{(0)}m_N) \frac{6m_* \bar{\theta}}{m_s - \bar{m}}, \end{aligned} \quad (42)$$

where the approximate SU(3) symmetry enforces many other LO relations between corrections to the octet masses. The second equation in Eq. (40) is particularly interesting, because it relates $\bar{g}_{0\eta}$ not directly to the nucleon mass, but to its derivatives with respect to m_s and \bar{m} . Through the Feynman-Hellmann theorem, these derivatives can be related to the nucleon σ terms

$$\sigma_{Nq} = m_q \langle N | \bar{q}q | N \rangle = m_q \frac{\partial \Delta m_N}{\partial m_q}. \quad (43)$$

We can thus write

$$\sqrt{3}\bar{g}_{0\eta}^{(0)} = -\left(\frac{\sigma_{Ns}^{(0)}}{m_s} - \frac{\sigma_{NI}^{(0)}}{2\bar{m}} \right) 4m_* \bar{\theta}, \quad (44)$$

where $\sigma_{NI} = \sigma_{Nu} + \sigma_{Nd}$.

In the rest of the paper we show that in most cases the relations between baryon mass splittings and \mathcal{X} baryon-pNG couplings break down already at NLO. The slow convergence of SU(3) baryon χ PT then renders the usefulness of these relations to be qualitative only. However, for each isospin-invariant coupling, there exists one relation that survives NLO and most of the N²LO corrections. These relations thus provide a powerful method to extract \mathcal{X} couplings from well-known T -even matrix elements. The most important example is the link between \bar{g}_0 and δm_N , which, as we discuss in Secs. IV and V, receives particularly small corrections.

IV. OCTET BARYON MASSES AND \mathcal{X} COUPLINGS AT NLO

In Fig. 1 we represent one-loop corrections to the baryon masses [Figs. 1(a) and 1(b)], and to \mathcal{X} octet-pNG couplings [Figs. 1(c) and 1(d)]. In dimensional regularization, Fig. 1(a) is finite and contributes to the octet masses and mass splittings at $\mathcal{O}(q^3)$. In particular, it affects the mass splittings δm_N , δm_Ξ , and δm_Σ through the kaon mass difference $m_{K^0}^2 - m_{K^+}^2 = B(m_d - m_u)$ and the η - π mixing angle ϕ . At the same order, diagrams with intermediate decuplet states contribute via Fig. 1(b). These diagrams have UV poles that are linear in the octet-decuplet splitting Δ and are absorbed by b_D , b_F , and b_0 . Figure 1(b) contributes to the nucleon mass splitting only through the kaon mass difference because of the vanishing of the octet-decuplet- η axial coupling. The mass splittings of the Ξ and Σ baryons receive contributions from both the kaon mass splitting and the η - π mixing.

All together, we find

$$\begin{aligned} \delta^{(1)}m_N &= \frac{(D^2 - 6DF - 3F^2)}{48\pi F_0^2} (m_{K^0}^3 - m_{K^+}^3) + \frac{(D - 3F)(D + F)}{8\pi F_0^2} \frac{\phi}{\sqrt{3}} (m_\eta^3 - m_\pi^3) \\ &\quad + \frac{\mathcal{C}^2}{144\pi^2 F_0^2} [f(m_{K^0}, \Delta) - f(m_{K^+}, \Delta)], \end{aligned} \quad (45)$$

$$\begin{aligned} \delta^{(1)}m_\Xi &= -\frac{(D^2 + 6DF - 3F^2)}{48\pi F_0^2} (m_{K^0}^3 - m_{K^+}^3) - \frac{(D + 3F)(D - F)}{8\pi F_0^2} \frac{\phi}{\sqrt{3}} (m_\eta^3 - m_\pi^3) \\ &\quad - \frac{7\mathcal{C}^2}{144\pi^2 F_0^2} [f(m_{K^0}, \Delta) - f(m_{K^+}, \Delta)] - \frac{\mathcal{C}^2}{12\pi^2 F_0^2} \frac{\phi}{\sqrt{3}} [f(m_\eta, \Delta) - f(m_\pi, \Delta)], \end{aligned} \quad (46)$$

$$\begin{aligned} \delta^{(1)}m_\Sigma &= \frac{DF}{4\pi F_0^2} (m_{K^0}^3 - m_{K^+}^3) + \frac{DF}{2\pi F_0^2} \frac{\phi}{\sqrt{3}} (m_\eta^3 - m_\pi^3) \\ &\quad + \frac{\mathcal{C}^2}{24\pi^2 F_0^2} [f(m_{K^0}, \Delta) - f(m_{K^+}, \Delta)] + \frac{\mathcal{C}^2}{12\pi^2 F_0^2} \frac{\phi}{\sqrt{3}} [f(m_\eta, \Delta) - f(m_\pi, \Delta)]. \end{aligned} \quad (47)$$

The loop function appearing in the decuplet diagrams is given by

$$f(m_K, \Delta) = \Delta \left(-\Delta^2 + \frac{3}{2}m_K^2 \right) L + \frac{\Delta}{6} \left[12m_K^2 - 10\Delta^2 + 3(3m_K^2 - 2\Delta^2) \ln \frac{\mu^2}{m_K^2} \right] + 2(m_K^2 - \Delta^2)^{3/2} \operatorname{arccot} \frac{\Delta}{\sqrt{m_K^2 - \Delta^2}}. \quad (48)$$

FIG. 1. $\mathcal{O}(q^3)$ corrections to the baryon masses and baryon-pNG \mathcal{X} couplings. Plain, double, and dashed lines denote octet baryons, decuplet baryons, and pNG bosons, respectively. Dotted vertices denote CP -even couplings, i.e., the octet-pNG axial couplings D and F and the decuplet-octet-pNG coupling \mathcal{C} . A square denotes a \mathcal{X} coupling.

L encodes the UV divergence and is defined as

$$L = \frac{1}{\varepsilon} + \ln 4\pi - \gamma_E, \quad (49)$$

where γ_E is the Euler constant. For the spin projector for decuplet fields in $d = 4 - 2\varepsilon$ dimensions, we used the definition of Ref. [57]. The poles are absorbed by defining the renormalized couplings b'_D and b'_F . We work in the $\overline{\text{MS}}$ scheme and define

$$b'_D = b_D - \Delta \frac{\mathcal{C}^2}{64\pi^2 F_\pi^2} L, \quad b'_F = b_F + \Delta \frac{5\mathcal{C}^2}{384\pi^2 F_\pi^2} L. \quad (50)$$

In the limit $\Delta \rightarrow 0$, the divergence disappears and f assumes the same form as the octet corrections,

$$\lim_{\Delta \rightarrow 0} f(m_K, \Delta) = \pi m_K^3. \quad (51)$$

The NLO corrections in Eqs. (45), (46), and (47) that do not involve the decuplet agree with Ref. [75]. Both octet and decuplet corrections respect the Coleman-Glashow relation.

In addition to the mass splittings, the tree-level relations between baryon masses and \mathcal{X} couplings involve the octet isospin-averaged masses. Baryon masses in the isospin limit were computed at NLO in Refs. [69,70] and at N²LO in Refs. [65,68,69,75,76]. At NLO

$$\Delta^{(1)} m_N = -\frac{1}{96\pi F_0^2} [2(5D^2 - 6DF + 9F^2)m_K^3 + 9(D + F)^2 m_\pi^3 + (D - 3F)^2 m_\eta^3] - \frac{\mathcal{C}^2}{48\pi^2 F_0^2} [f(m_K, \Delta) + 4f(m_\pi, \Delta)], \quad (52)$$

$$\begin{aligned} \Delta^{(1)} m_\Xi &= -\frac{1}{96\pi F_0^2} [2(5D^2 + 6DF + 9F^2)m_K^3 + 9(D - F)^2 m_\pi^3 + (D + 3F)^2 m_\eta^3] \\ &\quad - \frac{\mathcal{C}^2}{48\pi^2 F_0^2} [3f(m_K, \Delta) + f(m_\pi, \Delta) + f(m_\eta, \Delta)], \end{aligned} \quad (53)$$

$$\Delta^{(1)} m_\Sigma = -\frac{1}{96\pi F_0^2} [12(D^2 + F^2)m_K^3 + 4(D^2 + 6F^2)m_\pi^3 + 4D^2 m_\eta^3] - \frac{\mathcal{C}^2}{144\pi^2 F_0^2} [10f(m_K, \Delta) + 2f(m_\pi, \Delta) + 3f(m_\eta, \Delta)], \quad (54)$$

$$\Delta^{(1)} m_\Lambda = -\frac{1}{24\pi F_0^2} [(D^2 + 9F^2)m_K^3 + D^2(3m_\pi^3 + m_\eta^3)] - \frac{\mathcal{C}^2}{48\pi^2 F_0^2} [2f(m_K, \Delta) + 3f(m_\pi, \Delta)], \quad (55)$$

where the decuplet loop function f is given in Eq. (48).

NLO corrections to \bar{g}_i are induced by the \mathcal{X} three-pNG coupling in Eq. (12). This coupling is fixed at LO by the meson masses and does not involve a free coefficient. The relevant loop diagrams with octet and decuplet intermediate states are shown in Fig. 1. Figure 1(c) is finite, while Fig. 1(d) is UV divergent. Both diagrams contribute to \bar{g}_0 , \bar{g}_1 , and \bar{g}_2 , although the last two couplings are suppressed by \bar{m}/m_s and \bar{m}^2/m_s^2 , respectively. The corrections to \bar{g}_0 and \bar{g}_1 are given by

$$\begin{aligned} \bar{g}_0^{(1)} &= Bm_* \bar{\theta} \left\{ \frac{D^2 - 6DF - 3F^2}{24\pi F_0^2} \frac{m_{K^+}^2 + m_{K^0}^2 + m_{K^+} m_{K^0}}{m_{K^0} + m_{K^+}} \right. \\ &\quad \left. + \frac{(D - 3F)(D + F)}{12\pi F_0^2} \left(\frac{m_\eta^2 + m_\eta m_\pi + m_\pi^2}{m_\eta + m_\pi} \right) + \frac{\mathcal{C}^2}{72\pi^2 F_0^2} \frac{f(m_{K^0}, \Delta) - f(m_{K^+}, \Delta)}{m_{K^0}^2 - m_{K^+}^2} \right\}, \end{aligned} \quad (56)$$

$$\begin{aligned}
\bar{g}_1^{(1)} = & Bm_*\bar{\theta} \left(\frac{5D^2 - 6DF + 9F^2}{32\pi F_0^2} \left[m_{K^0} - m_{K^+} + (m_{K^0} + m_{K^+}) \frac{\phi}{\sqrt{3}} \right] \right. \\
& + \left[3 \frac{(D-3F)^2 m_\eta - 5(D+F)^2 m_\pi}{16\pi F_0^2} + \frac{(D^2 + 6DF - 3F^2) m_\eta^2 + m_\eta m_\pi + m_\pi^2}{6\pi F_0^2} \frac{m_\eta^2 + m_\eta m_\pi + m_\pi^2}{m_\eta + m_\pi} \right] \frac{\phi}{\sqrt{3}} \\
& + \frac{C^2}{32\pi^2 F_0^2} \left\{ f'(m_{K^0}, \Delta) - f'(m_{K^+}, \Delta) + \frac{\phi}{\sqrt{3}} [f'(m_{K^0}, \Delta) + f'(m_{K^+}, \Delta)] \right\} \\
& \left. - \frac{\phi}{\sqrt{3}} \frac{C^2}{6\pi^2 F_0^2} \left[3f'(m_\pi, \Delta) - 2 \frac{f(m_\eta, \Delta) - f(m_\pi, \Delta)}{m_\eta^2 - m_\pi^2} \right] \right). \quad (57)
\end{aligned}$$

The function f' entering the decuplet corrections to \bar{g}_1 is

$$f'(x, y) = \frac{1}{2x} \frac{\partial}{\partial x} f(x, y). \quad (58)$$

Notice that loops with only pions do not contribute to \bar{g}_0 at NLO, in accordance with the SU(2) result of Ref. [44]. The piece proportional to $(D+F)^2 m_\pi$ contributing to $\bar{g}_1^{(1)}$ is the same as found in SU(2) χ PT [22] once the LO identifications $D+F = g_A$ and $\phi/\sqrt{3} = (\delta m_\pi^2)/(2B\bar{m}\varepsilon)$, with $\delta m_\pi^2 = m_{\pi^\pm}^2 - m_{\pi^0}^2$, are made. In SU(2) χ PT this contribution appears at N³LO.

The one-loop diagrams in Fig. 1 give also the isospin-invariant nucleon-pNG couplings defined in Eq. (36). For these couplings we work in the isospin limit and find

$$\sqrt{3} \bar{g}_{0\eta}^{(1)} = \frac{Bm_*\bar{\theta}}{16\pi F_0^2} \left\{ m_K(5D^2 - 6DF + 9F^2) - 9(D+F)^2 m_\pi + (D-3F)^2 m_\eta + \frac{2C^2}{3} [f'(m_K, \Delta) - 8f'(m_\pi, \Delta)] \right\}, \quad (59)$$

$$\begin{aligned}
\bar{g}_{0N\Sigma K}^{(1)} = & Bm_*\bar{\theta} \left\{ \frac{5D^2 + 18DF - 15F^2}{48\pi F_0^2} \frac{m_K^2 + m_K m_\pi + m_\pi^2}{m_K + m_\pi} + \frac{(D-F)(D+3F)}{48\pi F_0^2} \frac{m_\eta^2 + m_\eta m_K + m_K^2}{m_K + m_\eta} \right. \\
& \left. + \frac{C^2}{288\pi^2 F_0^2} \left[10 \frac{f(m_K, \Delta) - f(m_\pi, \Delta)}{m_K^2 - m_\pi^2} + \frac{f(m_\eta, \Delta) - f(m_K, \Delta)}{m_\eta^2 - m_K^2} \right] \right\}, \quad (60)
\end{aligned}$$

$$\begin{aligned}
\sqrt{3} \bar{g}_{0N\Lambda K}^{(1)} = & Bm_*\bar{\theta} \left\{ -\frac{3(D^2 - 6DF - 3F^2)}{16\pi F_0^2} \frac{m_K^2 + m_\pi m_K + m_\pi^2}{m_K + m_\pi} \right. \\
& \left. + \frac{(D-F)(D+3F)}{16\pi F_0^2} \frac{m_\eta^2 + m_\eta m_K + m_K^2}{m_K + m_\eta} + \frac{C^2}{8\pi^2 F_0^2} \frac{f(m_K, \Delta) - f(m_\pi, \Delta)}{m_K^2 - m_\pi^2} \right\}. \quad (61)
\end{aligned}$$

Testing the relations at NLO

Armed with the NLO expressions for the baryon masses and the \mathcal{X} nucleon-pNG couplings, we investigate the relations found in Sec. III. We start with \bar{g}_0 , which is of the greatest phenomenological interest. We repeat the relations we want to test

$$\bar{g}_0 = \delta m_N \frac{m_*\bar{\theta}}{\bar{m}\varepsilon} = (\Delta m_\Xi - \Delta m_\Sigma) \frac{2m_*}{m_s - \bar{m}} \bar{\theta}. \quad (62)$$

As these relations hold at LO, it is sufficient to test the relation for the NLO corrections themselves. A comparison of Eq. (45) and Eq. (56) shows that it is possible to write

$$\bar{g}_0^{(1)} = 2B \left[\frac{\delta^{(1)} m_N^K}{m_{K^0}^2 - m_{K^+}^2} + \frac{1}{3} \left(\frac{\phi}{\sqrt{3}} \right)^{-1} \frac{\delta^{(1)} m_N^{\eta-\pi}}{m_\eta^2 - m_\pi^2} \right] m_*\bar{\theta}, \quad (63)$$

where $\delta^{(1)} m_N^K$ ($\delta^{(1)} m_N^{\eta-\pi}$) denotes the pieces of Eq. (45) induced by the kaon mass splitting (η - π mixing). Using the LO expression for the meson masses and mixing angle, this

simplifies into

$$\bar{g}_0^{(1)} = \delta^{(1)} m_N \frac{m_*}{\bar{m}\varepsilon} \bar{\theta}. \quad (64)$$

Thus, NLO corrections, with both octet and decuplet intermediate states, conserve the relation between \bar{g}_0 and δm_N .

Next we consider the second equality in Eq. (62). Using Eqs. (53) and (54), and expanding for simplicity the decuplet contributions in the limit $\Delta \rightarrow 0$, the NLO corrections to \bar{g}_0 can be expressed as

$$\begin{aligned}
\bar{g}_0 = & \left[(\Delta^{(1)} m_\Xi - \Delta^{(1)} m_\Sigma) + \frac{3(D^2 - 6DF - 3F^2) + C^2}{288\pi F_0^2} \right. \\
& \left. \times (m_K - m_\pi)^2 (m_K + 2m_\pi) \right] \frac{2m_*}{m_s - \bar{m}} \bar{\theta}. \quad (65)
\end{aligned}$$

So in addition to a term proportional to $\Delta^{(1)} m_\Xi - \Delta^{(1)} m_\Sigma$, there is a second term that violates the relation. This second term vanishes in the SU(3) limit, $m_s = \bar{m}$, and is nonanalytic in the quark masses. The severity of the breaking is best illustrated by plugging in numerical values. Up to NLO it is possible to

write

$$\begin{aligned} \frac{\bar{g}_0}{\Delta m_\Xi - \Delta m_\Sigma} &= \left[1 + \frac{3(D^2 - 6DF - 3F^2) + C^2}{288\pi F_0^2} \right. \\ &\quad \left. \times \frac{(m_K - m_\pi)^2(m_K + 2m_\pi)}{\Delta m_\Xi - \Delta m_\Sigma} \right] \frac{2m_*\bar{\theta}}{m_s - \bar{m}} \\ &= (1 - 0.7 + 0.2) \frac{2m_*\bar{\theta}}{m_s - \bar{m}}, \end{aligned} \quad (66)$$

where the second and third contributions in the second line are the octet and decuplet corrections, respectively. We used the observed value of the $\Xi - \Sigma$ mass splitting, $\Delta m_\Xi - \Delta m_\Sigma = 124$ MeV [2], and $F_0 = F_\pi$, the difference being higher order. We see that the tree-level relation is violated by a 50% correction and thus it is unsuitable for a precise determination of \bar{g}_0 .

Next we look at the \mathcal{N} couplings in Eq. (36). Using the NLO results for octet masses, we conclude that the following relations survive NLO corrections:

$$\sqrt{3}\bar{g}_{0\eta}^{(1)} = -\left(\frac{\sigma_{N_s}^{(1)}}{m_s} - \frac{\sigma_{NI}^{(1)}}{2\bar{m}}\right)4m_*\bar{\theta}, \quad (67)$$

$$\begin{aligned} \bar{g}_1^{(1)} &= \bar{g}_{0\eta}^{(1)}\phi + Bm_*\bar{\theta} \left[\frac{5D^2 - 6DF + 9F^2}{32\pi F_0^2} (m_{K^0} - m_{K^+}) \right. \\ &\quad \left. + \frac{1}{24\pi F_0^2} \frac{(D^2 + 6DF - 3F^2)(m_\eta - m_\pi)^2 + 6(D^2 + 3F^2)(m_\eta^2 - m_\pi^2)}{m_\eta + m_\pi} \frac{\phi}{\sqrt{3}} \right]. \end{aligned} \quad (70)$$

The first piece, proportional to $\bar{g}_{0\eta}$, respects the relation to the nucleon σ term. However, we were not able to find any useful relation respected by the remaining piece of Eq. (70). As numerically the violation of the relation is of similar size as the $\bar{g}_{0\eta}^{(1)}\phi$ part, the tree-level relation is of little use.

To assess the importance of corrections to the tree-level value of \bar{g}_1 , we evaluate Eqs. (31) and (57) using $b_D = 0.068$ GeV⁻¹ and $b_F = -0.209$ GeV⁻¹ (these values are discussed in Sec. VIB). We find

$$\frac{\bar{g}_1}{2F_\pi} = (0.85 + 1.0 + 0.85) \times 10^{-3} \bar{\theta}. \quad (71)$$

The first number is the LO contribution. The second and third numbers are the octet and decuplet contributions to the NLO corrections, Eq. (57). We see that NLO corrections are large, as big as the leading term, and the inclusion of the decuplet makes them even larger. Because there is no surviving relation between \bar{g}_1 and baryon masses or σ terms and the χ PT corrections show no sign of convergence, we conclude that in SU(3) χ PT there is no safe way to extract \bar{g}_1 from the baryon spectrum.

V. OCTET BARYON MASSES AND \mathcal{N} COUPLINGS AT N²LO

In Sec. IV we have seen that NLO corrections affect the octet baryon mass splittings and nucleon \mathcal{N} couplings in such a way that most LO tree-level relations between \mathcal{N} couplings and

$$\bar{g}_{0N\Sigma K}^{(1)} = -(\Delta^{(1)}m_\Sigma - \Delta^{(1)}m_N) \frac{2m_*\bar{\theta}}{m_s - \bar{m}}, \quad (68)$$

$$\sqrt{3}\bar{g}_{0N\Lambda K}^{(1)} = -(\Delta^{(1)}m_\Lambda - \Delta^{(1)}m_N) \frac{6m_*\bar{\theta}}{m_s - \bar{m}}. \quad (69)$$

The remaining LO relations in Eqs. (40), (41), and (42) are violated. We observe that NLO corrections do not spoil the relations if the baryons that enter the \mathcal{N} vertices are the same as those appearing in the mass combinations, while relations to masses of baryons that are not involved in the \mathcal{N} vertices are violated.

Finally, we discuss \bar{g}_1 . At tree level, \bar{g}_1 is closely related to $\bar{g}_{0\eta}$, $\bar{g}_1^{(0)} = \bar{g}_{0\eta}^{(0)}\phi$, as can be seen from Eqs. (35) and (40). This can be understood because at this order \bar{g}_1 is induced by the emission of an η meson by the nucleon and the consequent mixing of the η with a neutral pion. As was the case for $\bar{g}_{0\eta}^{(1)}$, the first two relations of Eq. (35) are violated at NLO; however, in this case also the third relation is violated. At this order, \bar{g}_1 receives a contribution identical to $\bar{g}_{0\eta}^{(1)}$, but in addition there are contributions from the kaon mass splitting and from η - π mixing in the internal pion and η propagators. Neglecting in this discussion the decuplet correction, we find

baryon masses are violated. The exceptions are the relations between \bar{g}_0 and the nucleon mass splitting δm_N and similar relations for the couplings $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ to $\Delta m_\Sigma - \Delta m_N$ and $\Delta m_\Lambda - \Delta m_N$. Furthermore, the link between $\bar{g}_{0\eta}$ and the nucleon σ term also survives NLO corrections. Of these couplings, \bar{g}_0 has the largest phenomenological impact as it contributes to the nucleon EDF at LO and gives rise to the dominant piece of the $\bar{\theta}$ -induced \mathcal{N} nucleon-nucleon potential. In Secs. VA and VB we therefore focus on δm_N and \bar{g}_0 . We discuss \bar{g}_1 in Sec. VC and the nucleon couplings involving η and kaons in Sec. VD.

We show that again all loop corrections affect δm_N and \bar{g}_0 in the same way, except for finite contributions that are quadratic in the isospin-breaking parameter ε and thus numerically suppressed. All LECs from $\mathcal{L}^{(4)}$ that are needed to absorb divergences in the loops appear in the same way in \bar{g}_0 and δm_N . The relation between \bar{g}_0 and δm_N is broken by additional, finite contributions to \bar{g}_0 from operators in $\mathcal{L}^{(4)}$, which do not contribute to δm_N . These contributions, however, scale as $B^2\bar{m}^2$ and not as $B^2m_s\bar{m}$. Even though the values of these LECs are currently not known, they should not affect the $\bar{g}_0 - \delta m_N$ relation in a significant way. Finally, SU(3)-breaking effects induce subleading pion and η tadpoles, which contribute to \bar{g}_0 but not to δm_N , thus violating the relation. We estimate these violations and show that our results allow for a precise extraction of \bar{g}_0 from available lattice evaluations of the strong part of the nucleon mass splitting.

FIG. 2. $\mathcal{O}(q^4)$ corrections to the baryon octet mass splittings. Circled dotted vertices denote SU(3) invariant couplings of Eqs. (22) and (23). Crosses denote insertions of the octet and decuplet baryon mass terms of Eq. (20). Other notation as in Fig. 1.

In what follows we calculate N²LO correction to the nucleon mass splitting (the nucleon average mass and the masses and mass splittings of the other octet baryons are given in Appendixes A and B) and \bar{g}_0 , including corrections owing to the baryon decuplet. We keep terms linear in the quark mass difference, ε , neglecting $\mathcal{O}(\varepsilon^2)$ contributions. We comment on these corrections briefly at the end of the section.

A. Corrections to the nucleon mass splitting

N²LO corrections to the nucleon and Δ mass splittings in SU(2) χ PT were considered in Ref. [67]. In SU(3) χ PT N²LO octet masses and mass splittings were considered in Ref. [75], in the infrared regularization scheme. Here we repeat the calculation in the heavy-baryon formalism and include corrections from the baryon decuplet. At $\mathcal{O}(q^4)$, baryon masses receive corrections from loops involving vertices in the Lagrangians $\mathcal{L}^{(2)}$, $\mathcal{L}_{\pi\pi}^{(2)}$, and $\mathcal{L}_{\text{rel}}^{(2)}$ in Eqs. (20), (22), and (23), respectively, and from tree-level insertions from the Lagrangian $\mathcal{L}^{(4)}$ in Eq. (24). The relevant loop diagrams are shown in Fig. 2. Figures 2(a)–2(f) show the contributions of octet intermediate states. Figure 2(a) includes the correction to the propagator. It contributes to the mass splittings in two ways, through the kaon mass splitting or η - π mixing, and through the on-shell relation, which relates $v \cdot p$ to the mass of the external baryon in the diagram. Figures 2(b) and 2(c) contain recoil corrections to the axial couplings D and F , and are proportional to $1/m_B$.

Figure 2(d) has a piece given by a recoil correction and a piece proportional to the LECs b_1 , b_2 , and b_3 . The LEC b_8 does not contribute to mass splittings, but only to isospin-averaged masses. Figures 2(e) and 2(f) have an insertion of the SU(3) breaking couplings b_D , b_F , and b_0 .

The diagrams in Fig. 2 are UV divergent and the divergences are absorbed by the counterterms in $\mathcal{L}^{(4)}$. Of the operators defined in Eq. (24), only d_1 , d_2 , d_3 , d_5 , and d_6 are relevant for mass splittings. Furthermore, d_i satisfy the relation in Eq. (26), implying that there are only four independent counterterms. We write

$$\begin{aligned}\delta m_N^{\text{ct}} &= (4B)^2 (2\bar{m}\varepsilon)(\bar{m}\tilde{d}_1 + m_s\tilde{d}_2), \\ \delta m_\Xi^{\text{ct}} &= (4B)^2 (2\bar{m}\varepsilon)(\bar{m}\tilde{d}_3 + m_s\tilde{d}_4), \\ \delta m_\Sigma^{\text{ct}} &= -(4B)^2 (2\bar{m}\varepsilon)[\bar{m}(\tilde{d}_3 + \tilde{d}_1) + m_s(\tilde{d}_4 + \tilde{d}_2)],\end{aligned}\quad (72)$$

where we neglected terms of order ε^2 , and \tilde{d}_i are defined as

$$\begin{aligned}\tilde{d}_1 &= -2(d_1 + d_2 + d_3 + d_5 + d_6), \\ \tilde{d}_2 &= 2d_1 - 2d_3 - d_5 - d_6, \\ \tilde{d}_3 &= 2(d_1 - d_2 + d_3 - d_5 + d_6), \\ \tilde{d}_4 &= -2d_1 + 2d_3 - d_5 + d_6.\end{aligned}\quad (73)$$

Because the counterterms satisfy the Coleman-Glashow relation, the divergences of the diagrams in Fig. 2 must do so as well. We have explicitly checked that this holds and that, at N²LO, Eq. (26) is only violated by the finite term [77]

$$\begin{aligned}\delta m_N + \delta m_\Xi + \delta m_\Sigma &= \frac{B(b_F D^2 + 2b_D D F)}{\pi^2 F_0^2} \left[(m_s - \bar{m}) m_K^2 \ln \frac{m_{K^0}^2}{m_{K^+}^2} - 2\bar{m}\varepsilon m_\pi^2 \ln \frac{m_K^2}{m_\pi^2} \right] \\ &\quad - \frac{C^2 B(9b_D + 12b_F + 7b_C)}{36\pi^2 F_0^2} \{ (m_s - \bar{m}) f_2^-(m_K, \Delta) - \bar{m}\varepsilon [f_2^+(m_K, \Delta) - 2f_2(m_\pi, \Delta)] \},\end{aligned}\quad (74)$$

where the decuplet loop function $f_2(x, y)$ is defined below in Eq. (81).

We now present our results for the nucleon mass splitting, after having subtracted the UV divergences in the $\overline{\text{MS}}$ scheme. To facilitate the comparison to loop corrections to \bar{g}_0 , we split the N²LO corrections to δm_N in three contributions. We start from

Figs. 2(b)–2(d) and the piece of Fig. 2(a) proportional to m_B^{-1} ,

$$\begin{aligned} \delta m_N^{(a,b,c,d)} = & (b_1 + b_2 + b_3) \frac{1}{8\pi^2 F_0^2} \left(m_{K^0}^4 - m_{K^+}^4 + m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) \\ & - (3b_1 + b_2 - b_3) \frac{\phi}{\sqrt{3}} \frac{1}{4\pi^2 F_0^2} \left(m_\pi^4 - m_\eta^4 + m_\pi^4 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^4 \ln \frac{\mu^2}{m_\eta^2} \right) - \frac{D^2 - 6DF - 3F^2}{96\pi^2 F_0^2 m_B} \\ & \times \left(m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) + \frac{(D - 3F)(D + F)}{16\pi^2 F_0^2 m_B} \frac{\phi}{\sqrt{3}} \left(m_\pi^4 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^4 \ln \frac{\mu^2}{m_\eta^2} \right). \end{aligned} \quad (75)$$

Here and in the following we omit the superscript (2). Figures 2(a) and 2(e) give

$$\begin{aligned} \delta m_N^{(a,e)} = & -8B\bar{m}\varepsilon (b_D + b_F) \frac{1}{16\pi^2 F_0^2} \left\{ (D + F)^2 m_\pi^2 \left(1 + 3 \ln \frac{\mu^2}{m_\pi^2} \right) \right. \\ & \left. + \frac{3D^2 + 2DF + 3F^2}{6} m_K^2 \left(1 + 3 \ln \frac{\mu^2}{m_K^2} \right) - \frac{m_s - \bar{m}}{36\bar{m}\varepsilon} (D + 3F)^2 g_2(m_{K^0}, m_{K^+}) \right\} \\ & - 4B\bar{m}\varepsilon (b_D - b_F) \frac{D}{12\pi^2 F_0^2} \left\{ (D - F) m_K^2 \left(1 + 3 \ln \frac{\mu^2}{m_K^2} \right) - \frac{m_s - \bar{m}}{6\bar{m}\varepsilon} (D - 3F) g_2(m_{K^0}, m_{K^+}) \right\}, \end{aligned} \quad (76)$$

where pion loops are proportional to the combination $b_D + b_F$, which determines δm_N at tree level, while kaon loops also give contributions proportional to $b_D - b_F$. Only pion and kaon loops contribute to $\delta m_N^{(a,e)}$. In the case of the η and of η - π mixing, the contributions of Figs. 2(a) and 2(e) exactly cancel.

Finally, Fig. 2(f) gives

$$\begin{aligned} \delta m_N^{(f)} = & -8B\bar{m}\varepsilon (b_D + b_F) \frac{1}{32\pi^2 F_0^2} \left\{ m_\pi^2 \left(1 + \ln \frac{\mu^2}{m_\pi^2} \right) + \frac{m_\eta^2}{3} \left(1 + \ln \frac{\mu^2}{m_\eta^2} \right) \right. \\ & \left. - \frac{\bar{m}}{(m_s - \bar{m})} \left(m_\pi^2 - m_\eta^2 + m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} \right) + m_K^2 \left(1 + \ln \frac{\mu^2}{m_K^2} \right) + \frac{\bar{m} + m_s}{2\bar{m}\varepsilon} g_1(m_{K^0}, m_{K^+}) \right\}. \end{aligned} \quad (77)$$

The loop functions g_1 and g_2 are defined as

$$g_1(m_{K^0}, m_{K^+}) = m_{K^0}^2 - m_{K^+}^2 + m_{K^0}^2 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^2 \ln \frac{\mu^2}{m_{K^+}^2}, \quad (78)$$

$$g_2(m_{K^0}, m_{K^+}) = m_{K^0}^2 - m_{K^+}^2 + 3m_{K^0}^2 \ln \frac{\mu^2}{m_{K^0}^2} - 3m_{K^+}^2 \ln \frac{\mu^2}{m_{K^+}^2}. \quad (79)$$

Eqs. (75), (76), and (77) reproduce the results of Ref. [75].

We then consider N²LO decuplet corrections to the baryon octet mass splittings. The relevant diagrams are depicted in Figs. 2(g) and 2(h). We give here the results for δm_N , while the contributions to the Ξ and Σ mass splittings can again be found in Appendix A.

The UV poles of the diagrams involving decuplet intermediate states have the form

$$f_2^{uv}(m, \Delta) = -(2\Delta^2 - m^2) L. \quad (80)$$

The divergence proportional to Δ^2 is absorbed by the $\mathcal{O}(\Delta^2)$ piece of the LECs b_D and b_F , while the divergence proportional to the quark mass is canceled by the counterterms \bar{d}_1 and \bar{d}_2 . After subtracting the UV poles, the decuplet contributions can be expressed in terms of the function

$$\begin{aligned} f_2(m, \Delta) = & -2\Delta^2 + (m^2 - 2\Delta^2) \ln \frac{\mu^2}{m^2} \\ & - 4\Delta \sqrt{m^2 - \Delta^2} \operatorname{arccot} \frac{\Delta}{\sqrt{m^2 - \Delta^2}}, \end{aligned} \quad (81)$$

and we define

$$f_2^\pm(m_K, \Delta) = [f_2(m_{K^0}, \Delta) \pm f_2(m_{K^+}, \Delta)]. \quad (82)$$

Figure 2(g) induces corrections to the mass splittings that are proportional to the LECs b_0 , b_D , and b_F ,

$$\begin{aligned} \delta m_N^{(g)} = & -\frac{\mathcal{C}^2}{8\pi^2 F_0^2} B\bar{m}\varepsilon (b_F + b_D) [8f_2(m_\pi, \Delta) + f_2^+(m_K, \Delta)] \\ & + \frac{\mathcal{C}^2}{24\pi^2 F_0^2} B[(m_s + 2\bar{m})b_0 + \bar{m}(b_D + b_F) \\ & + m_s(b_D - b_F)] f_2^-(m_K, \Delta), \end{aligned} \quad (83)$$

where we neglected relativistic corrections to the decuplet propagator. Figure 2(h) contains corrections that are induced by mass splittings of the decuplet, and are proportional to the

LEC b_C in Eq. (20):

$$\delta m_N^{(h)} = -\frac{b_C C^2}{36\pi^2 F_0^2} B \left\{ 2\bar{m}\varepsilon [10f_2(m_\pi, \Delta) + f_2^+(m_K, \Delta)] - \frac{m_s + 2\bar{m}}{2} f_2^-(m_K, \Delta) \right\}. \quad (84)$$

Contributions proportional to b_Δ in Eq. (20) can be absorbed by a redefinition of Δ and we did not explicitly consider them. If we neglect kaon loops, Eqs. (83) and (84) agree with the SU(2) calculation of Ref. [67].

B. N²LO corrections to \bar{g}_0

The N²LO corrections to \bar{g}_0 with octet and decuplet intermediate states are shown in Fig. 3. In addition to these diagrams, we need the nucleon wave function renormalization Z_N , and the pion wave function renormalization, Z_π . For the calculation of \bar{g}_0 , it is sufficient to compute them in the isospin limit $m_{K^0} = m_{K^+} = m_K$ and $\phi = 0$. Denoting $\delta Z_N = Z_N - 1$ and $\delta Z_\pi = Z_\pi - 1$, we have

$$\begin{aligned} \delta Z_N &= 3(D+F)^2 \frac{m_\pi^2}{64\pi^2 F_0^2} \left(1 + 3 \ln \frac{\mu^2}{m_\pi^2}\right) \\ &\quad + (5D^2 - 6DF + 9F^2) \frac{m_K^2}{96\pi^2 F_0^2} \left(1 + 3 \ln \frac{\mu^2}{m_K^2}\right) \\ &\quad + (D-3F)^2 \frac{m_\eta^2}{192\pi^2 F_0^2} \left(1 + 3 \ln \frac{\mu^2}{m_\eta^2}\right) \\ &\quad + \frac{C^2}{32\pi^2 F_0^2} [f_2(m_K, \Delta) + 4f_2(m_\pi, \Delta)], \end{aligned} \quad (85)$$

$$\begin{aligned} \delta Z_\pi &= -\frac{m_\pi^2}{24\pi^2 F_0^2} \left(1 + \ln \frac{\mu^2}{m_\pi^2}\right) - \frac{m_K^2}{48\pi^2 F_0^2} \left(1 + \ln \frac{\mu^2}{m_K^2}\right) \\ &\quad - \frac{16B}{F_0^2} [(m_s + 2\bar{m})L_4 + \bar{m}L_5]. \end{aligned} \quad (86)$$

Finally, at this order one has to consider the correction arising from expressing F_0 in the LO \mathcal{X} pion-nucleon coupling in terms of F_π . At N²LO, the relation between F_0 and F_π is [42]

$$\begin{aligned} \delta F_\pi &= 1 - \frac{F_\pi}{F_0} \\ &= -\frac{m_\pi^2}{16\pi^2 F_0^2} \left(1 + \ln \frac{\mu^2}{m_\pi^2}\right) - \frac{m_K^2}{32\pi^2 F_0^2} \left(1 + \ln \frac{\mu^2}{m_K^2}\right) \\ &\quad - \frac{8B}{F_0^2} [(m_s + 2\bar{m})L_4 + \bar{m}L_5]. \end{aligned} \quad (87)$$

We compute the diagrams in Fig. 3 with on-shell baryons and an incoming pion with energy $v \cdot q$ and zero three-momentum $\vec{q} = 0$. The on-shell condition can be written as

$$\begin{aligned} v \cdot K &= \frac{1}{2}(v \cdot p + v \cdot p') \\ &= \frac{1}{2}(m_i + m_f - 2m_B) + \frac{\vec{p}^2 + \vec{p}'^2}{2m_B}, \end{aligned} \quad (88)$$

$$v \cdot q = (v \cdot p' - v \cdot p) = m_f - m_i, \quad (89)$$

where $m_{f,i}$ are the corrections to the masses of the baryons in the final and initial state and m_B is the common mass of the octet. For the diagrams in Fig. 3, it is enough to use the tree-level expression of the baryon masses, which are given in Eqs. (25) and (27).

The counterterms are determined from Eq. (24). Operators d_1 - d_6 contribute in the same way to \bar{g}_0 and δm_N and thus preserve the tree-level relation. Some of the remaining counterterms do spoil the \bar{g}_0 - δm_N relation. These corrections are discussed in Sec. V B.

We move on to the loop diagrams, which we discuss in some detail. The contribution of Figs. 3(a)–3(d) to \bar{g}_0 can be written as

$$\bar{g}_0^{(a,b,c,d)} = \delta m_N^{(a,b,c,d)} \frac{m^*}{\bar{m}\varepsilon} \bar{\theta}, \quad (90)$$

where we applied the LO expressions of the meson masses and mixing angle. In this expression $\delta m_N^{(a,b,c,d)}$ is given in Eq. (75). Both in Eq. (75) and in Eq. (90), only the pieces of Figs. 2(a) and 3(a) proportional to $1/m_B$ are considered.

When we combine the contribution of diagram 3(a) proportional to $v \cdot K$, that on-shell becomes proportional to the average nucleon mass, the nucleon wave function renormalization Z_N , and Figs. 3(e) and 3(g), we obtain

$$\bar{g}_0^{(a,e,g)} + \bar{g}_0^{(0)} \delta Z_N = \delta m_N^{(a,e)} \frac{m^*}{\bar{m}\varepsilon} \bar{\theta}, \quad (91)$$

where $\bar{g}_0^{(0)}$ is given in Eq. (30) and $\delta m_N^{(a,e)}$ in Eq. (76). Contributions from the η meson in the loop diagrams in Figs. 3(e) and 3(g) are canceled by the sum of wave function renormalization and Fig. 3(a) in the same way as it happens for the nucleon mass splitting. Figures 3(k) and 3(l) mutually cancel.

Then we consider Figs. 3(f), 3(h), 3(i), and 3(j). These diagrams need to be combined with one-loop corrections to the pion wave function renormalization and to the decay constant F_0 . Considering these effects, we find

$$\bar{g}_0^{(f,h,i,j)} + \bar{g}_0^{(0)} \left(\frac{1}{2} \delta Z_\pi - \delta F_\pi \right) = \delta m_N^{(f)} \frac{m^*}{\bar{m}\varepsilon} \bar{\theta}, \quad (92)$$

where $\delta m_N^{(f)}$ is in Eq. (77). Notice that the contribution of the LECs L_4 and L_5 cancels between the pion wave function renormalization and δF_π .

Finally, we consider the decuplet corrections in Figs. 3(o)–3(q). An explicit calculation shows that Fig. 3(o) and Figs. 3(p) and 3(q) are in direct correspondence with Figs. 2(g) and 2(h), respectively, once the decuplet corrections to the nucleon wave function renormalization are included. Thus, N²LO decuplet corrections do not spoil the \bar{g}_0 - δm_N relation.

The results in this section show that all UV-divergent contributions to \bar{g}_0 up to N²LO can be expressed in terms of the strong part of the nucleon mass splitting. However, at this order, we find some finite violations of the relation, which we discuss now.

N²LO violations of the relation between \bar{g}_0 and δm_N

There are three types of N²LO corrections to \bar{g}_0 that cannot be written in terms of δm_N . The first of these corrections arises from additional counterterm contributions to \bar{g}_0 . As discussed

FIG. 3. N^2 LO contributions to \mathcal{X} nucleon couplings. Squares denote \mathcal{X} pNG and baryon-pNG couplings. Other notation is as in Figs. 1 and 2.

in the preceding section, the counterterms d_1 to d_8 in Eq. (24) conserve the relation, while d_9 - d_{16} can potentially spoil it. It can be seen that d_9 and d_{12} do not contribute to \mathcal{X} baryon-pNG couplings at this order, while d_{15} and d_{16} only contribute to \bar{g}_1 . The remaining correction can then be written as

$$\bar{g}_0^{\text{ct}} = \delta m_N^{\text{ct}} \frac{m_* \bar{\theta}}{\bar{m} \varepsilon} - (4B)^2 \tilde{d}_5 (2\bar{m}) m_* \bar{\theta}, \quad (93)$$

where \tilde{d}_5 is the combination

$$\tilde{d}_5 = 2d_{10} + 4d_{11} + 3d_{13} + 3d_{14}. \quad (94)$$

The combination of LECs \tilde{d}_5 is thus not related to mass splittings in the baryon spectrum, but could, in principle, be extracted from a precise analysis of nucleon-pion scattering. In practice, however, these LECs appear at too high order

and are not well constrained [78]. This additional counterterm is present in SU(2) χ PT as well, where it also appears at N^2 LO [44]. Both in SU(2) and in SU(3), the additional contribution to \bar{g}_0 scales as \bar{m} and not as m_s , in contrast to the terms in Eq. (72). Considering the good convergence of SU(2) χ PT, we expect these corrections to be of the expected size, m_π^2/Λ_χ^2 , of the order of a few percent.

The second type of contributions that violates the \bar{g}_0 - δm_N relation appears owing to additional isospin violation. We have not calculated these contributions systematically, but give just one example. Figure 3(a) induces, besides the component proportional to $v \cdot K$ discussed above, a contribution proportional to the energy transfer $v \cdot q$. Such a term gives rise to a correction to \bar{g}_0 that is quadratic in the quark mass splitting ε^2 , which is not matched by an analogous correction to δm_N .

This correction is proportional to the tree-level pion-nucleon coupling, and we can write

$$\frac{\delta\bar{g}_{0,v,q}^{(c)}}{\bar{g}_0^{(0)}} = \frac{D^2 - 6DF - 3F^2}{256\pi^2 F_0^2} \times \frac{m_{K^0}^4 - m_{K^+}^4 + 2m_{K^0}^2 m_{K^+}^2 \ln \frac{m_{K^+}^2}{m_{K^0}^2}}{m_{K^0}^2 - m_{K^+}^2}. \quad (95)$$

Plugging in the values of the axial couplings and kaon masses, Eq. (95) gives

$$\frac{\delta\bar{g}_{0,v,q}^{(c)}}{\bar{g}_0^{(0)}} \simeq -2 \times 10^{-6}, \quad (96)$$

which is completely negligible. We do not expect significant corrections from the remaining $\mathcal{O}(\varepsilon^2)$ contributions that we did not compute.

Finally, the third type of violations arises from tadpole contributions, Figs. 3(m) and 3(n). In the $\mathcal{O}(q^4)$ meson Lagrangian, the operators L_7 and L_8 generate pion and η tadpoles. In addition, one has to consider one-loop diagrams with one external η or π_0 , and the \mathcal{X} three-pNG vertex of Eq. (12). Together with the two-pNG vertices from the baryon mass terms, the tadpoles generate contributions to \bar{g}_0 and \bar{g}_1 . Up to corrections of $\mathcal{O}(\varepsilon^2)$, the contribution to \bar{g}_0 arises only from η tadpoles and is proportional to $\bar{g}_0^{(0)}$. We find

$$\frac{\delta\bar{g}_0^{(m,n)}}{\bar{g}_0^{(0)}} = \frac{m_\pi^2}{3m_\eta^2} \left\{ \frac{32B}{F_0^2} (L_8^r + 3L_7)(m_s - \bar{m}) + \frac{1}{32\pi^2 F_0^2} \left[2m_K^2 \ln \frac{\mu^2}{m_K^2} + m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} - 3m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} \right] \right\}, \quad (97)$$

where here we have adopted the subtraction scheme of Ref. [42] to define the renormalized coupling L_8^r , while L_7 is not renormalized. Using the values of L_7 and L_8 discussed in Sec. II A, we can estimate the tadpole corrections to be

$$\frac{\delta\bar{g}_0^{(m,n)}}{\bar{g}_0^{(0)}} = (-0.5 \pm 1.3) \times 10^{-2}. \quad (98)$$

We thus expect the relation between \bar{g}_0 and δm_N to hold up to a few percent.

C. N²LO corrections to \bar{g}_1

We have shown that already at NLO no relations between \bar{g}_1 and baryon masses survive. However, in SU(2) χ PT, where \bar{g}_1 only appears at N²LO, it can be shown that part of \bar{g}_1 can be related to the pion mass splitting induced by the quark mass difference [44]. At the same order, there appears an unknown

direct contribution to \bar{g}_1 which has been estimated to be small by use of resonance saturation techniques in Ref. [73]. In this section, we study this relation in SU(3) χ PT and study the effects of the SU(3) LO and NLO contributions to \bar{g}_1 that are missing in SU(2).

The SU(2) relation of \bar{g}_1 to the strong component of the pion mass splitting can be recovered by studying the tadpole diagrams, Figs. 3(m) and 3(n), and, in particular, the contribution of the pion tadpole. In SU(3) χ PT the pion tadpole receives contributions from the LECs L_7 and L_8 and from one-loop diagrams with insertion of the \mathcal{X} three-pNG vertex in Eq. (12). When these contributions are combined, the coupling of the pion to the vacuum given by

$$\mathcal{L}_{\text{tad}} = -2Bm_*\bar{\theta} f_{\text{tad}} F_0\pi^0, \quad (99)$$

where the function f_{tad} is

$$f_{\text{tad}} = \frac{48B}{F_0^2} \bar{m}\varepsilon (3L_7 + L_8^r) + \frac{1}{32\pi^2 F_0^2} \left(m_{K^0}^2 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^2 \ln \frac{\mu^2}{m_{K^+}^2} \right) + \frac{\phi}{\sqrt{3}} \frac{1}{32\pi^2 F_0^2} \left(2m_K^2 \ln \frac{\mu^2}{m_K^2} + 3m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} - 5m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} \right). \quad (100)$$

It is possible to show that f_{tad} is related to the pion mass splitting in the large m_s limit, more precisely,

$$\lim_{m_s \rightarrow \infty} f_{\text{tad}} = - \lim_{m_s \rightarrow \infty} \frac{\delta m_\pi^2}{m_\pi^2 \varepsilon}, \quad (101)$$

where δm_π^2 denotes the component of the pion mass splitting induced by $m_d - m_u$. The expressions of the pion mass and mass splitting at one loop can be found in Refs. [42,79].

The pion tadpole induces a correction to \bar{g}_1 , of the form

$$\delta\bar{g}_1^{(m,n)} = -8B(2b_0 + b_D + b_F) f_{\text{tad}} m_* \bar{\theta}, \quad (102)$$

which, using Eqs. (27) and (101), can be expressed in terms of the light-quark σ term and δm_π^2 as

$$\delta\bar{g}_1^{(m,n)} = - \left(\bar{m} \frac{d}{d\bar{m}} \Delta^{(0)} m_N \right) \frac{\delta m_\pi^2}{m_\pi^2} \Big|_{m_s \rightarrow \infty} \frac{1 - \varepsilon^2}{\varepsilon}, \quad (103)$$

where we expanded also m_*/\bar{m} in the large m_s limit. Equation (103) is exactly what is found in SU(2) [44]. Notice, however, that in SU(3) it is not possible to express \bar{g}_1 in terms of the full pion mass splitting, but only of its large m_s limit.

To estimate the pion tadpole correction to \bar{g}_1 , we use the extraction of the light-quark σ term of Ref. [80]. In this paper, the SU(3) χ PT expressions of the nucleon mass and σ term are fitted to lattice data, and the LO contribution to the light-quark nucleon σ term is found to be

$$\bar{m} \frac{d\Delta^{(0)} m_N}{d\bar{m}} = 65 \pm 19 \text{ MeV}. \quad (104)$$

Using Eq. (104), together with L_7 and L_8 discussed in Sec. II A, the pion tadpole contribution to \bar{g}_1 is

$$\frac{\delta \bar{g}_1^{(m,n)}}{2F_\pi} = -(1.9 \pm 3.7) \times 10^{-3} \bar{\theta}. \quad (105)$$

The central value is in reasonable agreement with the estimate of Ref. [22], while the larger errors stem mainly from the uncertainties on L_7 and L_8 and the partial cancellation between L_7 and L_8 in the combination $3L_7 + L_8$.

Equation (103) is only a subset of the N²LO corrections to \bar{g}_1 . In addition, one should consider the loop diagrams in Fig. 3, the η tadpole, contributions from corrections to η - π mixing, and N²LO counterterms. We have not computed these corrections, because, as we discuss now, they are not particularly instructive.

Comparing Eqs. (105) and (71), we see that the contribution of the pion tadpole, which is formally N²LO, is comparable with the LO and NLO pieces of \bar{g}_1 . This is not surprising, because the LO and NLO terms vanish in the limit $m_s \rightarrow \infty$, and thus are suppressed by powers of \bar{m}/m_s . However, at N²LO \bar{g}_1 starts to receive contributions that are finite in the $m_s \rightarrow \infty$ limit, pion tadpoles being one such example. Equations (71) and (105) show that for \bar{g}_1 the suppression owing to inverse powers of m_s or Λ_χ is similar. An analogous observation was made for δm_π^2 , which is also determined at LO by the η - π mixing angle [42]. Thus, we conclude that the SU(3) χ PT power counting does not provide a good organizational principle for \bar{g}_1 . Currently, the best possible estimates are those based on SU(2) [22], which, however, are also affected by large uncertainties, leaving the determination of this important coupling in an unsatisfactory status. For clarity we repeat the SU(2) estimate of Ref. [22] here,

$$\frac{\bar{g}_1^{\text{SU}(2)}}{2F_\pi} = -(3.4 \pm 1.5) \times 10^{-3} \bar{\theta}, \quad (106)$$

which is partially based on a resonance saturation estimate of an unknown N²LO LEC [73] and on the tree-level relation

$\delta m_\pi^2 = (\varepsilon^2/4)m_\pi^4/(m_K^2 - m_\pi^2)$. The error in Eq. (106) is perhaps slightly underestimated. Including the uncertainty on the pion mass splitting, either through the estimate of higher-order corrections [42], or using the error on the extraction of Ref. [81] $\delta m_\pi^2 = (87 \pm 55) \text{ MeV}^2$, would raise the 45% uncertainty in Eq. (106) to about 70%. We stress that even with this large uncertainty, the SU(2) determination of \bar{g}_1 is incompatible with the LO SU(3) tree-level estimate in Eq. (71). Finally, we note that Eq. (106) does not include yet a higher-order contribution arising from the \mathcal{T} three-pion vertex.¹ This contribution enhances the estimate in Eq. (106) by roughly 50% [22,28], making the tree-level estimate of \bar{g}_1 even less reliable.

The large uncertainty on \bar{g}_1 dominates the uncertainty of light-nuclear EDMs when expressed in terms of $\bar{\theta}$ directly [35]. It also affects the EDMs of diamagnetic atoms, but there the nuclear uncertainty associated with the complicated nuclear many-body problem is still larger. Nevertheless more theoretical work on the size of \bar{g}_1 could significantly increase the precision of EDM analyses.

D. Other \mathcal{T} nucleon couplings

The relations of $\bar{g}_{0\eta}$, $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0N\Lambda K}$ to the nucleon σ term, the nucleon- Σ and nucleon- Λ mass splittings, can be checked in a way analogous to what done in Secs. V A and V B for \bar{g}_0 and δm_N . The expressions for Δm_N , Δm_Σ , and Δm_Λ are given in Appendix B. In addition, one needs the expressions of the baryon and meson wave function renormalizations and the expression of F_K and F_η as function of F_0 , which we also give in Appendix B. After all the ingredients are put together, it is possible to show that the loop contributions to the \mathcal{T} couplings satisfy

$$\sqrt{3}\bar{g}_{0\eta}^{(2)} = \bar{g}_{0\eta}^{(\text{loop})} + \bar{g}_{0\eta}^{(0)} \left(\delta Z_N + \frac{1}{2} \delta Z_\eta - \delta F_\eta \right) = - \left(\frac{\sigma_{Ns}^{(2)}}{m_s} - \frac{\sigma_{Nl}^{(2)}}{2\bar{m}} \right) 4m_* \bar{\theta}, \quad (107)$$

$$\bar{g}_{0N\Sigma K}^{(2)} = \bar{g}_{0N\Sigma K}^{(\text{loop})} + \bar{g}_{0N\Sigma K}^{(0)} \left[\frac{1}{2} (\delta Z_N + \delta Z_\Sigma + \delta Z_K) - \delta F_K \right] = - (\Delta^{(2)} m_\Sigma - \Delta^{(2)} m_N) \frac{2m_* \bar{\theta}}{m_s - \bar{m}}, \quad (108)$$

$$\sqrt{3}\bar{g}_{0N\Lambda K}^{(2)} = \bar{g}_{0N\Lambda K}^{(\text{loop})} + \bar{g}_{0N\Lambda K}^{(0)} \left[\frac{1}{2} (\delta Z_N + \delta Z_\Lambda + \delta Z_K) - \delta F_K \right] = - (\Delta^{(2)} m_\Lambda - \Delta^{(2)} m_N) \frac{6m_* \bar{\theta}}{m_s - \bar{m}}. \quad (109)$$

Equations (107), (108), and (109) include all the loop corrections, with the exception of the $v \cdot q$ contribution to Fig. 3(a). In the case of $\bar{g}_{0\eta}$, $v \cdot q = 0$, and this contribution vanishes. For $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$, this contribution violates the tree-level relations, as in the case of \bar{g}_0 . However, for \bar{g}_0 the breaking is proportional to ε^2 , while for couplings involving the nucleon and the Σ or Λ baryons it goes as $(m_s - \bar{m})^2$, and thus is potentially larger. We find

$$\frac{\delta \bar{g}_{0N\Sigma K, v \cdot q}^{(2)}}{\bar{g}_{0N\Sigma K}^{(0)}} = \frac{1}{512\pi^2 F_0^2} \left[(D^2 - 18DF + 9F^2) \frac{m_K^4 - m_\pi^4 - 2m_K^2 m_\pi^2 \ln \frac{m_K}{m_\pi}}{m_K^2 - m_\pi^2} + 9(D - F)^2 \frac{m_K^4 - m_\eta^4 - 2m_K^2 m_\eta^2 \ln \frac{m_K}{m_\eta}}{m_K^2 - m_\eta^2} \right] \simeq -0.015, \quad (110)$$

¹In SU(3) χ PT this contribution already appears at NLO and is identified with the piece proportional to $(D + F)^2 m_\pi$ in Eq. (57).

$$\frac{\delta \bar{g}_{0N\Lambda K, v,q}}{\bar{g}_{0N\Lambda K}^{(0)}} = -\frac{1}{512\pi^2 F_0^2} \left[3(3D^2 + 2DF + 3F^2) \frac{m_K^4 - m_\pi^4 - 2m_K^2 m_\pi^2 \ln \frac{m_K^2}{m_\pi^2}}{m_K^2 - m_\pi^2} \right. \\ \left. + (D + 3F)^2 \frac{m_K^4 - m_\eta^4 - 2m_K^2 m_\eta^2 \ln \frac{m_K^2}{m_\eta^2}}{m_K^2 - m_\eta^2} \right] \simeq -0.035. \quad (111)$$

Therefore, also for $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$, these violations are only a few percent.

The other contributions that violate the tree-level relations are the tadpole diagrams, Figs. 3(m) and 3(n), and the counterterms d_9 - d_{16} . For the nucleon- Σ and nucleon- Λ couplings, the tadpole contribution is proportional to the tree level, and we can write

$$\frac{\delta \bar{g}_{0N\Sigma K}^{(m,n)}}{\bar{g}_{0N\Sigma K}^{(0)}} = \frac{\delta \bar{g}_{0N\Lambda K}^{(m,n)}}{\bar{g}_{0N\Lambda K}^{(0)}} = -\frac{15m_\eta^2 - 7m_\pi^2}{48m_\eta^2} \left[\frac{32B}{F_0^2} (L_8^r + 3L_7)(m_s - \bar{m}) \right. \\ \left. + \frac{1}{32\pi^2 F_0^2} \left(2m_K^2 \ln \frac{\mu^2}{m_K^2} + m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} - 3m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} \right) \right], \quad (112)$$

where, again, we have used the subtraction scheme of Ref. [42]. Using the values of L_7 and L_8^r discussed in Sec. II A, we find that the tadpole corrections amount to no more than 10%.

In the case of the η , the tadpole corrections are not proportional to the tree level

$$\frac{\delta \bar{g}_{0\eta}^{(m,n)}}{\bar{g}_{0\eta}^{(0)}} = -\left(1 - \frac{m_\pi^2}{3m_\eta^2} + \frac{2b_0 + b_D + b_F}{b_D - 3b_F} \right) \left[\frac{32B}{F_0^2} (L_8^r + 3L_7)(m_s - \bar{m}) \right. \\ \left. + \frac{1}{32\pi^2 F_0^2} \left(2m_K^2 \ln \frac{\mu^2}{m_K^2} + m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} - 3m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} \right) \right]. \quad (113)$$

In this case, the estimate of the tadpole corrections is affected by larger uncertainties. Nonetheless, using the tree-level values of b_D and b_F , $b_D = 0.068 \text{ GeV}^{-1}$ and $b_F = -0.209 \text{ GeV}^{-1}$, and expressing $2b_0 + b_D + b_F$ in terms of the LO contribution to the light-quark nucleon σ term, Eq. (104), we get that the tadpole corrections to $\bar{g}_{0\eta}$ come in at 30%.

Finally, the operators in the Lagrangian $\mathcal{L}^{(4)}$ can also violate the tree-level relations. The counterterms d_1 - d_8 , which are needed to absorb the divergences in the baryon mass, respect the relations, as one expects. The operators d_9 - d_{11} only contribute to the \mathcal{X} couplings, and we find

$$\frac{\sqrt{3}\delta \bar{g}_{0\eta}^{(ct)}}{m_*\bar{\theta}} = -(4B)^2(6d_{10} - 4d_{11} + 9d_{13} - 3d_{14}) \frac{2}{3}(2m_s + \bar{m}) + (4B)^2 8 \left(\frac{4}{3}d_{11} + 2d_{14} + 3d_{15} + d_{16} \right) (m_s - \bar{m}), \quad (114)$$

$$\frac{\delta \bar{g}_{0N\Sigma K}^{(ct)}}{m_*\bar{\theta}} = (4B)^2(2d_{10} - 4d_{11} + 3d_{13} - 3d_{14})(m_s + \bar{m}), \quad (115)$$

$$\frac{\delta \bar{g}_{0N\Lambda K}^{(ct)}}{m_*\bar{\theta}} = (4B)^2(6d_{10} + 4d_{11} + 9d_{13} + 3d_{14})(m_s + \bar{m}). \quad (116)$$

We cannot give a precise estimate of the corrections in Eqs. (114)–(116), owing to the ignorance of the LECs d_{10} , d_{11} , and d_{13} – d_{16} . However, we see that the corrections to $\bar{g}_{0\eta}$ scale, at most, as m_η^2/Λ_χ^2 , and to $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ as m_K^2/Λ_χ^2 . Taking $\Lambda_\chi = 4\pi F_\pi$, the counterterm corrections should be around 15%–20%, of similar size as the tadpole contribution.

VI. DISCUSSION

A. Best estimates of the \mathcal{X} couplings

In this section we give the best estimates of the \mathcal{X} couplings by using the relations in Eqs. (33) and (67)–(69) that do not suffer from large SU(3) χ PT corrections.

The coupling \bar{g}_0 is related to the strong contribution the nucleon mass splitting for which there are now several lattice

QCD calculations [27,82–86]. The first three calculations [82–84] were performed with only a single lattice spacing and with pion masses $m_\pi \gtrsim 250 \text{ MeV}$. According to the FLAG Lattice Averaging Group standards [41], these results would not be included in averages of lattice QCD predictions. The next calculation [85] was performed with $m_\pi \gtrsim 283 \text{ MeV}$ and four lattice spacings. According to the FLAG criterion, these results would be included in an average, but perhaps do not have all the systematics under complete control. The final two calculations [27,86], although performed by the same group, are independent from each other and are performed with multiple lattice spacings and with pion masses at or near their physical value. Both calculations include effects on the splitting from QED. In the first case, QED was not included in the sea quarks, while in the second, the entire calculation

included the effects of QED. The strong contribution to the nucleon mass splitting from both of these calculations would receive the “green star” from FLAG.

There are only a small number of results that pass the FLAG criterion. For a final determination of the $m_d - m_u$ contribution to δm_N from lattice QCD, one must have more results. In this case, the exclusion of the first three results mostly stems from the use of a single lattice spacing. In the mass splitting, the leading discretization effects exactly cancel, because the lattice regulator used in those works respects flavor symmetry. We therefore chose to include all the results [27,82–86] to construct a lattice average. However, we assign a weight penalty to the first three calculations. This follows the averaging scheme in Refs. [26,87]: The weight factor is chosen to be

$$w_i = \frac{y_i}{\sigma_i^2}, \quad (117)$$

where σ_i are the given statistical and systematic uncertainties in the given lattice QCD calculation combined in quadrature and $y_i = 1$ for the first three calculations [82–84], $y_i = 2$ for Ref. [85], and $y_i = 3$ for the most recent two calculations [27,86], with these weights chosen somewhat arbitrarily. This weighted average yields

$$\delta m_N = 2.49 \pm 0.17 \text{ MeV}. \quad (118)$$

Substituting this in Eq. (33) together with ε , Eq. (4), we obtain

$$\frac{\bar{g}_0}{2F_\pi} = (15.5 \pm 2.0 \pm 1.6) \times 10^{-3} \bar{\theta}. \quad (119)$$

The first uncertainty comes from combining those on δm_N and ε in quadrature, while the second is a conservative estimate of the theoretical error associated to the N²LO corrections discussed in Sec. VB. This estimate agrees with the recent determination in Ref. [22] based on SU(2) χ PT. Because the relation to the nucleon mass splitting is preserved, the only difference compared to SU(2) is attributable to the \bar{m}/m_s correction in Eq. (3), which is tiny. In addition, the error in Eq. (119) is slightly larger than in Ref. [22] owing to inclusion of higher-order chiral corrections.

The fact that the relations of $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ to, respectively, $m_\Sigma - m_N$ and $m_\Lambda - m_N$ are violated only by finite N²LO corrections allows for a reliable estimate of these couplings. In this case, the electromagnetic contribution to the isospin averaged masses is relatively small, and we can use the experimentally observed baryon masses, $\Delta m_\Sigma = 1193$ MeV, $\Delta m_\Lambda = 1116$ MeV, and $\Delta m_N = 939$ MeV, with negligible experimental uncertainties. We use the ratio m_s/\bar{m} in Eq. (4) to obtain

$$\frac{\bar{g}_{0N\Sigma K}}{2F_K} = -(36 \pm 1 \pm 11) \times 10^{-3} \bar{\theta}, \quad (120)$$

$$\frac{\bar{g}_{0N\Lambda K}}{2F_K} = -(44 \pm 1 \pm 13) \times 10^{-3} \bar{\theta}. \quad (121)$$

The first error is given by the errors on m_s/\bar{m} and ε , while the second estimates the effects of the finite terms that break the relations. In this case the breaking scales as m_K^2/Λ_χ^2 which we estimate at the 30% level; see the discussion in Sec. VD.

Finally, $\bar{g}_{0\eta}$ is expressed in terms of the nucleon σ terms. For the light-quark σ term, the most precise value is determined from low-energy πN scattering with the most recent determination from Ref. [88],

$$\sigma_{NI} = 59.1 \pm 3.5 \text{ MeV}. \quad (122)$$

This number is consistent with earlier χ PT analyses [89–91]. This quantity can also be determined with lattice QCD. However, there is significantly larger uncertainty from the lattice determination arising from a few systematic issues. The primary means to determine this quantity is invoking the Feynman-Hellman theorem, Eq. (43), with a large spread of results; see Ref. [92] for a recent review. There is a surprising “phenomenological” pion mass dependence of the nucleon mass found in lattice QCD calculations [93,94], yielding $m_N \simeq 800 \text{ MeV} + m_\pi$ over a wide range of pion masses, including the physical point. This, in turn, provides an estimate of $\sigma_{NI} = 67 \pm 5 \text{ MeV}$. The best lattice QCD calculation, which also would receive a “green star” from FLAG, was performed with pion masses as light as $m_\pi \sim 190 \text{ MeV}$ [80] with the result

$$\sigma_{NI} = 39_{-8}^{+18} \text{ MeV}. \quad (123)$$

It will likely be years before lattice QCD results can compete with the dispersive πN scattering determination of Ref. [88] in Eq. (122).

For the scalar strange content of the nucleon, there is no close second to the lattice QCD determination, although the results are not yet mature. Reference [87] compared all recent lattice QCD calculations of σ_{Ns} [76,80,95–101] (where only Ref. [80] evaluated all systematics) and found a systematically low value, as compared with prior estimates from SU(3) baryon χ PT. An average value was determined,

$$\sigma_{Ns} = 40 \pm 10 \text{ MeV}. \quad (124)$$

Thus, our estimate for the coupling using inputs from Eqs. (122) and (124) is

$$\frac{\bar{g}_{0\eta}}{2F_\eta} = (115 \pm 8 \pm 35) \times 10^{-3} \bar{\theta}, \quad (125)$$

where the first error is from the uncertainty in the σ terms and the second from the N²LO corrections discussed in Sec. VD.

B. A comment on baryon EDMs

The $\bar{\theta}$ -induced EDMs of the baryon octet in the framework of three-flavored χ PT have been studied in great detail in Refs. [23,43,102,103] (for a calculation of the nucleon EDM arising from the CKM phase, see Ref. [104]). In these works U(3)_L × U(3)_R χ PT is applied to calculate the EDMs of the whole baryon octet up to NLO in the chiral power counting. Compared to the SU(3) × SU(3) χ PT framework used in this work, the main difference arises from the dynamical inclusion of the η' meson. However, as shown in Ref. [102], these effects can be absorbed in a redefinition of a counterterm contributing to the EDMs of the charged baryons p , Σ^\pm , and Ξ^- .

In the case of CP violation induced by the $\bar{\theta}$ term, the first contributions to baryon EDMs arise at $\mathcal{O}(q^2/\Lambda_\chi^3)$. At this order, the baryon EDMs depend on only two combinations of

FIG. 4. An example of an NLO two-loop correction to baryon EDMs involving the \mathcal{X} three-pNG vertex. Several other diagrams with different topologies appear at the same order.

counterterms in addition to one-loop diagrams involving the \mathcal{X} nucleon-pNG vertices \bar{g}_0 , $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0N\Lambda K}$ and analogous couplings of the other octet baryons to pions and kaons. At NLO, no new counterterms appear but several additional one-loop diagrams contribute with no additional LECs. At NLO, one finds the first contributions from neutral mesons and thus those from $\bar{g}_{0\eta}$ and \bar{g}_1 . Corrections induced by \bar{g}_1 , being proportional to $\bar{m}\varepsilon/m_s$, are small and have been neglected in Refs. [23,102]. In SU(2) χ PT, \bar{g}_1 only contributes at N³LO [24]. The baryon-pNG vertices are related to b_D and b_F using the tree-level relations in Eqs. (30) and (37)–(39) and values for $\{b_D, b_F\} = \{0.068, -0.209\}$ GeV⁻¹ are obtained by fitting the baryon masses to the tree-level expressions in Eq. (27). The two unknown counterterms are fitted to lattice data of the neutron and proton EDMs and the EDMs of the other baryons are predicted. It is found that NLO contributions are significant, in particular for nonphysical large pion masses that are typically used in lattice evaluations of the nucleon EDM.

One class of diagrams has not been considered in these works. This class consists of diagrams involving the \mathcal{X} three-pNG vertices. Despite being two loop, these diagrams are of order $\mathcal{O}(q^3/\Lambda_\chi^4)$ and thus contribute to baryon EDMs at NLO,² and can be potentially large. An example of such a two-loop diagram is shown in Fig. 4. A two-loop calculation is beyond the scope of this work, but we note here that some of the two-loop diagrams involve a one-loop subpiece with the topology of Fig. 1(c). Thus, at least part of these corrections are taken into account by including one-loop corrections to \bar{g}_0 , $\bar{g}_{0\eta}$, $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0N\Lambda K}$; that is, they are automatically taken into account if the baryon-pNG couplings are obtained from the relation to baryon masses that survive higher-order corrections. Of course, a better assessment of the strangeness contribution to the nucleon EDM requires the full two-loop calculation. In two-flavor χ PT \mathcal{X} three-pion couplings arise only at subleading order, implying that two-loop diagrams as the one depicted in Fig. 4 only contribute at N³LO and can thus be neglected.

In Table I, a comparison is given between the tree-level predictions in Eqs. (30) and (37)–(39) using $\{b_D, b_F\} = \{0.068, -0.209\}$ GeV⁻¹ and the values obtained in Sec. VIA. The two predictions agree well for the couplings to kaons.

²These diagrams are NLO because the three-pNG vertices appear at lower order than the tree-level \mathcal{X} baryon-pNG vertices used in the LO one-loop diagrams. Although the extra loop comes with a suppression of $(q/\Lambda_\chi)^2$, the relative size of the three-pNG vertex brings in a factor Λ_χ/q , making the two-loop diagrams genuine NLO corrections.

TABLE I. Comparison between tree-level predictions for \mathcal{X} nucleon-pNG couplings using $\{b_D, b_F\} = \{0.068, -0.209\}$ GeV⁻¹ (see Refs. [23,102]) and the predictions from Sec. VIA. All values are in units of $10^{-3}\bar{\theta}$.

| | Tree-level values ($\times 10^{-3}\bar{\theta}$) | Values obtained here ($\times 10^{-3}\bar{\theta}$) |
|--------------------------------|---|--|
| $\bar{g}_0/(2F_\pi)$ | 26 | 15.5 ± 2.5 |
| $\bar{g}_{0\eta}/(2F_\eta)$ | 56 | 115 ± 37 |
| $\bar{g}_{0N\Sigma K}/(2F_K)$ | -41 | -36 ± 11 |
| $\bar{g}_{0N\Lambda K}/(2F_K)$ | -48 | -44 ± 13 |

$\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ are only 10% smaller, and the predictions agree within errors. The coupling to pions is more affected, being roughly 40% smaller, with a smaller uncertainty (this point was already made in Ref. [73] based on LO SU(3) χ PT arguments). This can be easily understood, because using the values of b_D and b_F obtained by fits to the tree-level isospin-averaged octet masses is equivalent to use the relation of \bar{g}_0 to $\Delta m_\Xi - \Delta m_\Sigma$, rather than the robust relation to δm_N . Finally, using the nucleon σ terms rather than the tree-level prediction in terms of b_D and b_F leads to a considerably larger $\bar{g}_{0\eta}$. This is a reflection of the poor convergence of the SU(3) expansion for the nucleon σ term. However, our best estimate is affected by a relatively large error owing to unknown LECs that enter at N²LO.

We conclude that SU(3) corrections to the baryon-pNG couplings moderately alter the tree-level predictions. We do not expect that the 40% shift in \bar{g}_0 significantly affects the nucleon EDM extractions performed in Ref. [102,103], as the lattice data are not yet sensitive to nonzero values of \mathcal{X} nucleon-pNG couplings [25]. (Notice, however, that the analysis of Ref. [25] did not include the more recent results of Ref. [18].) For future extractions based on more precise lattice data with pion masses closer to the physical point, we recommend the values (and uncertainties³) of the \mathcal{X} couplings given in the third column of Table I.

Finally, we discuss decuplet corrections to the nucleon EDMs, which have not been calculated in the literature. The leading \mathcal{X} Lagrangian induced by $\bar{\theta}$, Eq. (20), contains nonderivative \mathcal{X} decuplet-pNG and octet-pNG couplings, but no \mathcal{X} decuplet-octet-pNG couplings. Such couplings require, to conserve angular momentum, at least two derivatives and thus are suppressed in the χ PT power counting. The lack of a \mathcal{X} nucleon-decuplet-pNG vertex at the order at which we work implies that there are no LO one-loop contributions to the nucleon EDM. In three-flavor χ PT, two-loop contributions appear at NLO owing to diagrams with similar topology as Fig. 4, but with an internal decuplet propagator. However, as argued above, these corrections are partially taken into account if the \mathcal{X} baryon-pNG couplings are inferred from the protected

³Some of the uncertainties on the couplings arise from N²LO corrections and thus are formally higher order than considered in the baryon EDM calculation. They were estimated in Refs. [102,103] by varying the renormalization scale appearing in the chiral logarithms.

relations. We therefore do not expect decuplet corrections to play an important role in the study of baryon EDMs. We note that contributions from the decuplet EDMs to octet EDMs only appear at N²LO.

The nucleon Schiff moment

An alternative way of extracting the \mathcal{X} nucleon-pNG couplings is to study the momentum dependence of the nucleon EDFF. While the EDM gets both long-range and short-range contributions, the momentum dependence of the EDFF at NLO

is finite and determined purely by loop diagrams. Short-range effects enter only at N²LO. The full momentum dependence of the EDFF is given in Refs. [23,102], with the omission of two-loop diagrams as the one depicted in Fig. 4. Denoting the nucleon [proton] EDFF as $F_n(\vec{q}^2)$ [$F_p(\vec{q}^2)$], the Schiff moment is defined as

$$S_{n,p} = - \left. \frac{dF_{n,p}(\vec{q}^2)}{d\vec{q}^2} \right|_{\vec{q}^2=0} \quad (126)$$

and is given at NLO by

$$S_n = - \frac{e}{(4\pi F_\pi)^2} \left[\frac{\bar{g}_0 g_A}{6m_\pi^2} \left(1 - \frac{5\pi m_\pi}{4m_N} \right) - \frac{\bar{g}_{0N\Sigma K}(D-F)}{6m_K^2} \left(1 - \frac{5\pi m_K}{4m_N} - \pi \frac{\Delta m_\Sigma - \Delta m_N}{2m_K} \right) \right], \quad (127)$$

$$S_p = \frac{e}{(4\pi F_\pi)^2} \left[\frac{\bar{g}_0 g_A}{6m_\pi^2} \left(1 - \frac{5\pi m_\pi}{4m_N} \right) + \frac{\bar{g}_{0N\Sigma K}(D-F)}{12m_K^2} \left(1 - \frac{5\pi m_K}{4m_N} - \pi \frac{\Delta m_\Sigma - \Delta m_N}{2m_K} \right) - \frac{\bar{g}_{0\Lambda N\Sigma}(D+3F)}{12\sqrt{3}m_K^2} \left(1 - \frac{5\pi m_K}{4m_N} - \pi \frac{\Delta m_\Lambda - \Delta m_N}{2m_K} \right) \right], \quad (128)$$

where we expressed the results in Refs. [23,102] in terms of \bar{g}_0 , $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0\Lambda N\Sigma}$ and of the nucleon- Σ and nucleon- Λ mass splittings and we used $D+F=g_A$. Considering only pion loops, these results agree with the SU(2) calculations of Refs. [24,105,106]. In SU(3) χ PT, the neutron and proton Schiff moments have two components. The contribution of pion loops is isovector and its typical scale is determined by the pion mass. In addition, both neutron and proton receive contributions from kaon loops, which vary on the scale of the kaon mass. The neutron only receives contributions from loops involving the Σ baryon, while the proton from both Σ and Λ intermediate states. One can immediately see that the kaon contributions receive large NLO corrections, indeed larger than the LO, being $\pi m_K/m_N \sim 2$. However, the neutron and proton Schiff moments receive their largest contributions from pion loops, so that in this case the poor convergence is not a big issue quantitatively.

Using the values of the \mathcal{X} couplings in Table I, we find

$$S_0 = \frac{S_n + S_p}{2} = -(0.5 \pm 0.7) \times 10^{-5} \bar{\theta} e \text{ fm}^3, \\ S_1 = \frac{S_p - S_n}{2} = [(7.6 \pm 1.4) - (2.4 \pm 0.6)] \times 10^{-5} \bar{\theta} e \text{ fm}^3, \quad (129)$$

where the isoscalar Schiff moment is given purely by kaon loops. For S_1 we have listed separately the contributions of pion and kaon loops. The uncertainties only include the errors from the \mathcal{X} couplings, while we do not give an estimate of the theoretical error from higher-order corrections. Because the isovector Schiff moment is very sensitive to \bar{g}_0 , using our best estimate in Eq. (119) results in nucleon Schiff moments that are smaller by roughly a factor 2 than found in Ref. [23]. It is interesting that even in SU(3) χ PT the Schiff moment is predominantly isovector, owing to accidental cancellations between the pieces proportional to $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0\Lambda N\Sigma}$.

While a measurement of the nucleon EDFF is not going to happen in the foreseeable future, the predictions (127), (128), and (129) can be compared to lattice evaluations of the EDFFs. In particular, lattice calculations performed at several values of light-quark masses could provide enough information to disentangle the contributions from the pion-nucleon and kaon-nucleon \mathcal{X} couplings, which have different dependence on \bar{m} and m_s . This would provide a method to check the values of the \mathcal{X} couplings.

C. A few comments on the \mathcal{X} nucleon-nucleon potential

The EDMs of light nuclei and diamagnetic atoms obtain important contributions from the \mathcal{X} nucleon-nucleon potential. In case of the QCD $\bar{\theta}$ term, this potential is expected to be dominated by one-pion-exchange diagrams. In particular, because \bar{g}_1 is suppressed with respect to \bar{g}_0 , often only the latter is taken into account. However, we stress that for certain \mathcal{X} quantities such as the EDMs of the light nuclei ^2H , ^6Li , and ^9Be [107–109], the ^{225}Ra Schiff moment [8], or the ^{181}Ta magnetic quadrupole moment [110], the nuclear matrix element for \bar{g}_1 is significantly larger than that for \bar{g}_0 . In these cases \bar{g}_1 should be included in the analysis. The value of \bar{g}_0 extracted in Sec. VIA can be immediately used in the existing calculations of EDMs that use the lowest-order chiral \mathcal{X} potential induced by the QCD $\bar{\theta}$ term [72]. However, as discussed in Sec. VC, at the moment chiral symmetry only allows a determination of \bar{g}_1 , and thus of the \mathcal{X} isospin-breaking potential, with a relatively large uncertainty.

Nuclear EDMs can obtain important contributions from \mathcal{X} nucleon-nucleon contact interactions. In case of strong CP violation, such interactions appear at N²LO only and are thus expected to be small. The corresponding potential is of the form [72]

$$V_{SR}(\vec{q}) = -\frac{i}{2} (\bar{C}_1 + \bar{C}_2 \boldsymbol{\tau}^{(1)} \cdot \boldsymbol{\tau}^{(2)}) (\vec{\sigma}^{(1)} - \vec{\sigma}^{(2)}) \cdot \vec{q}, \quad (130)$$

where $\vec{\sigma}^{(i)}$ and $\vec{\tau}^{(i)}$ denote the spin and isospin of nucleon i and \vec{q} is the momentum transfer $\vec{q} = \vec{p} - \vec{p}'$, with \vec{p} (\vec{p}') the center-of-mass momentum of the incoming (outgoing) nucleons. $\bar{C}_{1,2}$ are LECs that in SU(2) χ PT scale as $\bar{C}_{1,2} = \mathcal{O}(\bar{\theta} m_\pi^2 / F_\pi^2 \Lambda_\chi^3)$. \bar{C}_2 is needed to absorb the divergences in two-pion exchange (TPE) diagrams, while \bar{C}_1 is not renormalized at this order [72]. The TPE contribution can be used to give a rough estimate of \bar{C}_2 [22],

$$|\bar{C}_2| = \mathcal{O}\left[\frac{\bar{g}_0 g_A^3}{F_\pi^2 (4\pi F_\pi)^2}\right] \simeq 2 \times 10^{-3} \bar{\theta} \text{ fm}^3, \quad (131)$$

and \bar{C}_1 is expected to be of similar size. Clearly, this estimate is not very precise and below we derive an independent estimate of the sizes of $\bar{C}_{1,2}$.

For nuclear physics applications, the typical momentum transfer is smaller than the kaon and η masses. We can estimate the size of $\bar{C}_{1,2}$ by calculating contributions from $\bar{g}_{0\eta}$, $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0N\Lambda K}$ to the potential and expanding them in powers of $|\vec{q}|/m_{K,\eta}$, where $|\vec{q}| \sim m_\pi$. In principle, the same can be done for decuplet corrections but these only appear at higher order because of the absence of a \mathcal{X} nucleon-decuplet-pNG vertex (see the discussion at the end of Sec. VIB).

The coupling to η , $\bar{g}_{0\eta}$ contributes to the potential at tree level, providing a finite piece to \bar{C}_1 . We obtain

$$\bar{C}_1 = \frac{\bar{g}_{0\eta}}{2F_\eta^2} \frac{D-3F}{\sqrt{3}} \frac{1}{m_\eta^2} = -8 \times 10^{-3} \bar{\theta} \text{ fm}^3, \quad (132)$$

$$\bar{C}_{1\Sigma} = \frac{9\bar{g}_{0N\Sigma K}(D-F)}{8F_K^2(4\pi F_K)^2} \left\{ \left[1 - \frac{3}{2}(D-F)^2 \right] v(m_K, \Delta_\Sigma) - \frac{(D+3F)^2}{6} v(m_K, \Delta_{\Sigma\Lambda}) + \frac{2}{3} \right\}, \quad (133)$$

$$\bar{C}_{2\Sigma} = -\frac{\bar{g}_{0N\Sigma K}(D-F)}{8F_K^2(4\pi F_K)^2} \left\{ \left[1 + \frac{3}{2}(D-F)^2 \right] v(m_K, \Delta_\Sigma) - \frac{(D+3F)^2}{2} v(m_K, \Delta_{\Sigma\Lambda}) + \frac{2}{3} \right\},$$

while those with the \mathcal{X} nucleon- Λ coupling give

$$\bar{C}_{1\Lambda} = -\frac{3\bar{g}_{0N\Lambda K}(D+3F)}{8\sqrt{3}F_K^2(4\pi F_K)^2} \left\{ \left[1 - \frac{(D+3F)^2}{6} \right] v(m_K, \Delta_\Lambda) - \frac{3}{2}(D-F)^2 v(m_K, \Delta_{\Sigma\Lambda}) + \frac{2}{3} \right\}, \quad (134)$$

$$\bar{C}_{2\Lambda} = -\frac{\bar{g}_{0N\Lambda K}(D+3F)}{8\sqrt{3}F_K^2(4\pi F_K)^2} \left\{ \left[1 - \frac{(D+3F)^2}{2} \right] v(m_K, \Delta_\Lambda) + \frac{3}{2}(D-F)^2 v(m_K, \Delta_{\Sigma\Lambda}) + \frac{2}{3} \right\}.$$

The function $v(m_K, \Delta)$ is defined as

$$v(m_K, \Delta) = \left(\ln \frac{\mu^2}{m_K^2} - \frac{2}{3} - 2 \frac{\Delta}{\sqrt{m_K^2 - \Delta^2}} \operatorname{arccot} \frac{\Delta}{\sqrt{m_K^2 - \Delta^2}} \right), \quad (135)$$

and $\Delta_\Sigma = \Delta m_\Sigma - \Delta m_N$ and $\Delta_\Lambda = \Delta m_\Lambda - \Delta m_N$. The first diagram in Fig. 5 can involve Σ and Λ intermediate states at the same time, and thus is a function of Δ_Σ and Δ_Λ . In this case, we find that the loop function is well approximated by evaluating v in $\Delta_{\Sigma\Lambda} = (\Delta m_\Sigma + \Delta m_\Lambda - 2\Delta m_N)/2$ and ignoring contributions proportional to $\Delta m_\Sigma - \Delta m_\Lambda$.

We can estimate the contributions to the potentials by setting the scale $\mu = m_N = 939$ MeV, and using the values for the \mathcal{X} couplings in Eqs. (120) and (121),

$$\bar{C}_{1\Sigma} = -0.5 \times 10^{-3} \bar{\theta} \text{ fm}^3, \quad \bar{C}_{2\Sigma} = 0.1 \times 10^{-3} \bar{\theta} \text{ fm}^3, \quad (136)$$

$$\bar{C}_{1\Lambda} = 1.0 \times 10^{-3} \bar{\theta} \text{ fm}^3, \quad \bar{C}_{2\Lambda} = -0.5 \times 10^{-3} \bar{\theta} \text{ fm}^3. \quad (137)$$

FIG. 5. Contribution of $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ to the nucleon-nucleon \mathcal{X} potential. Single lines denote nucleon external states. Double lines denote Λ or Σ baryon propagators. Only one possible ordering per topology is shown.

which is in reasonable agreement with Eq. (131) considering the uncertainty of that estimate.

The couplings $\bar{g}_{0N\Sigma K}$ and $\bar{g}_{0N\Lambda K}$ contribute to the nucleon potential only at one loop and are thus formally suppressed by two powers in the chiral counting compared to the one-pion-exchange contribution. Nevertheless, because the \mathcal{X} coupling to kaons are somewhat larger than \bar{g}_0 , their contribution might be sizable. The corresponding diagrams are shown in Fig. 5. They are similar to the TPE diagrams studied in Ref. [72], with the exception that only triangle and crossed diagrams are possible because box diagrams are forbidden by strangeness conservation. We computed the diagrams in the limit $|\vec{q}| \ll m_K$, while keeping the mass difference between the nucleon and the strange baryons in the baryon propagator. The diagrams contribute both to \bar{C}_1 and to \bar{C}_2 . After canceling the UV poles, diagrams involving the \mathcal{X} nucleon- Σ coupling give

Thus, the contributions of the nucleon-kaon couplings to the \mathcal{X} potentials are below the naive dimensional analysis (NDA) estimate of $\bar{C}_{1,2}$ in Eq. (131) and significantly smaller than the contribution of $\bar{g}_{0\eta}$.

The contributions of $\bar{C}_{1,2}$ to the EDMs of ${}^3\text{He}$ and ${}^3\text{H}$ were studied in Refs. [21,22]. Unfortunately, these operators are very sensitive to the choice of the T -conserving strong-interaction potential and results vary by about an order of magnitude. Here we use the results of Ref. [22] obtained with the N²LO chiral potential [111], which gives the largest dependence on $\bar{C}_{1,2}$. The EDM of ${}^3\text{He}$ is, ignoring uncertainties, given by

$$d_{{}^3\text{He}} = 0.9d_n - 0.03d_p + \left(-0.11 \frac{\bar{g}_0}{2F_\pi} - 0.40 \bar{C}_1 F_\pi^3 + 0.88 \bar{C}_2 F_\pi^3 \right) e \text{ fm}. \quad (138)$$

Focusing on the pieces proportional to \bar{g}_0 and \bar{C}_1 and using the estimates in Eqs. (119) and (132), we find

$$d_{{}^3\text{He}} - 0.9d_n + 0.03d_p = (-1.8 + 0.3) \times 10^{-3} \bar{\theta} e \text{ fm}, \quad (139)$$

where the first (second) number is the contribution of \bar{g}_0 (\bar{C}_1). The short-range potential provides a 15% correction compared to the one-pion-exchange contribution,⁴ well within the $\mathcal{O}(20\%)$ uncertainties of the nuclear calculation of the latter (see Ref. [22] for a more detailed discussion). It seems safe to neglect the short-range contributions to, at least, light-nuclear EDMs in case of the QCD $\bar{\theta}$ term. This conclusion is in line with Refs. [21,22].

VII. CONCLUSION

In this work we have investigated higher-order SU(3) flavor-breaking corrections to the relations between \mathcal{X} meson-nucleon couplings and baryon masses in the framework of SU(3) χ PT. For each isospin-invariant \mathcal{X} nucleon-meson coupling induced by the QCD $\bar{\theta}$ term, we have identified one relation to baryon mass splittings or sigma terms which is not spoiled by loop corrections up to N²LO. The determination of these couplings from spectroscopy is therefore independent of the convergence issues of SU(3) baryon χ PT through this order. In Sec. VIA we have used the conserved relations to derive precise values for \mathcal{X} couplings. We recommend these values and corresponding uncertainties in future lattice QCD extractions of the nucleon EDM and in studies of nuclear \mathcal{X} quantities such as EDMs, Schiff moments, and magnetic quadrupole moments.

The most important of these relations is the one linking the pion-nucleon coupling \bar{g}_0 to the nucleon mass splitting induced by $m_d - m_u$, the quark mass difference. We find that all loop corrections, with the exception of small terms quadratic in $m_d - m_u$, affect \bar{g}_0 and δm_N in the same way, so that at N²LO

we can express \bar{g}_0 in terms of δm_N , plus corrections that are not enhanced by chiral logarithms and are not proportional to m_s . We stress that, at this order, the effects of strangeness on \bar{g}_0 are completely buried in δm_N and thus accounted for when using lattice calculations of δm_N with dynamical strange quarks. We conservatively estimate the impact of terms violating the relation between \bar{g}_0 and δm_N to be about 10%. Thus, available lattice calculations of δm_N make it possible to determine \bar{g}_0 with 15% uncertainty. Further reduction of the errors will require improvements of the lattice calculations of the nucleon mass splitting, but also the determination of the unknown LECs that enter at $\mathcal{O}(q^4)$, Eq. (93), which are not related to baryon masses. Using the tree-level relation to $\Delta m_\Xi - \Delta m_\Sigma$, as often done in the literature, overestimates \bar{g}_0 by about 50%. It will be interesting to see if a direct extraction of \bar{g}_0 from the lattice, e.g., from the momentum dependence of the nucleon EDFF, will give a value compatible with Eq. (119).

Similarly, the \mathcal{X} couplings of the nucleon to the η meson, $\bar{g}_{0\eta}$, and the couplings involving kaons, $\bar{g}_{0N\Xi K}$ and $\bar{g}_{0N\Lambda K}$, are determined, respectively, by the nucleon σ term and by the mass differences of the nucleon and Σ and Λ baryons. In this case, the importance of the terms breaking the relation is larger, because they scale as m_K^2/Λ_χ^2 rather than m_π^2/Λ_χ^2 , and the corrections are estimated to be 30%. These couplings contribute to the nucleon EDM at LO, but, as discussed in Sec. VIC, they do not considerably affect the \mathcal{X} nucleon-nucleon potential induced by the QCD $\bar{\theta}$ term and therefore play a minor role in the calculation of \mathcal{X} nuclear observables.

For the phenomenologically interesting coupling \bar{g}_1 , all LO relations to baryon mass splittings and σ terms obtain $\mathcal{O}(100\%)$ corrections already at NLO and higher-order corrections are even larger. We see no pattern of convergence and conclude that SU(3) χ PT does not provide a reliable method to extract a value of \bar{g}_1 . This coupling plays an important role in many interesting \mathcal{X} observables such as the deuteron EDM and the ${}^{225}\text{Ra}$ Schiff moment, such that the lack of a robust relation to the baryon spectrum is unfortunate. In this case, the SU(2) χ PT extraction discussed in Sec. VC is more reliable but nevertheless suffers from a large uncertainty. This uncertainty could be reduced by more precise evaluations of the pion mass splitting induced by the quark mass difference.

As a byproduct of our study, we have obtained expressions for the octet baryon masses and mass splittings at N²LO in SU(3) χ PT. For diagrams involving octet intermediate state, our results reproduce the findings of Ref. [75]. We also included the effects of the decuplet baryons on the mass splittings of the nucleon, Ξ , and Σ baryons. The N²LO expressions of the octet masses and mass splittings depend on several LECs, which cannot be determined purely from experimental data. Given the poor convergence and/or lack of convergence of SU(3) baryon χ PT [62,63,113,114], it is not clear that they can meaningfully be determined from a comparison with lattice QCD either.

In this work we have focused on strong CP violation, but it would be interesting to extend the study to higher-dimensional CP -violating operators. In many scenarios of BSM physics, large nucleon and nuclear EDMs are induced by qCEDMs. However, the sizes of the nucleon EDMs and \mathcal{X} pion-nucleon couplings $\bar{g}_{0,1}$ are poorly known [8,29], leading to large

⁴A similar conclusion can be drawn by inserting the value of the $\bar{g}_{0\eta}$ coupling in the results of Ref. [112], where η exchange was considered explicitly.

uncertainties in the analysis of EDM constraints on BSM physics (see, for instance, Ref. [115]). Just as for the $\bar{\theta}$ term, it is possible to derive LO relations between qCEDM-induced \mathcal{X} pion-nucleon couplings and baryon mass splittings induced by CP -even quark chromomagnetic dipole moments [28], the chiral partners of the qCEDMs. The baryon mass splittings can be evaluated on the lattice providing a method to accurately evaluate $\bar{g}_{0,1}$. However, the relations have only been studied at LO and they might suffer from large higher-order corrections [116]. Finally, a recent evaluation [117] of the neutron EDM in SU(3) χ PT found a much larger dependence on the strange qCEDM than previous studies based on QCD sum rules [32,118]. As qCEDMs typically scale with the quark mass, this would strongly impact neutron EDM constraints on BSM scenarios. However, the analysis of Ref. [117] is based on LO SU(3) χ PT and, as demonstrated in this work, higher-order corrections might strongly affect the results.

APPENDIX A: N²LO CORRECTIONS TO MASS SPLITTINGS OF THE Σ AND Ξ BARYONS

In this appendix we give the expression of the loop contributions to δm_{Ξ} and δm_{Σ} at N²LO. The counterterm contributions are given in Eq. (72), and the violation to the Coleman-Glashow relation is given in Eq. (74). The loop functions g_1 and g_2 are defined in Eq. (78), while $f_2(x, y)$ and $f_2^{\pm}(x, y)$ are defined in Eqs. (81) and (82). The octet contributions agree with Ref. [75], while the decuplet corrections are new results.

(i) Ξ . The contribution of the relativistic corrections and of the two-pion couplings b_1 , b_2 , and b_3 is

$$\begin{aligned} \delta m_{\Xi}^{(a,b,c,d)} = & -(b_1 - b_2 + b_3) \frac{1}{8\pi^2 F_0^2} \left(m_{K^0}^4 - m_{K^+}^4 + m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) \\ & + (3b_1 - b_2 - b_3) \frac{\phi}{\sqrt{3}} \frac{1}{4\pi^2 F_0^2} \left(m_{\pi}^4 - m_{\eta}^4 + m_{\pi}^4 \ln \frac{\mu^2}{m_{\pi}^2} - m_{\eta}^4 \ln \frac{\mu^2}{m_{\eta}^2} \right) + \frac{D^2 + 6DF - 3F^2}{96\pi^2 F_0^2 m_B} \\ & \times \left(m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) - \frac{(D-F)(D+3F)}{16\pi^2 F_0^2 m_B} \frac{\phi}{\sqrt{3}} \left(m_{\pi}^4 \ln \frac{\mu^2}{m_{\pi}^2} - m_{\eta}^4 \ln \frac{\mu^2}{m_{\eta}^2} \right). \end{aligned} \quad (A1)$$

Loop corrections involving the operators b_D and b_F give

$$\begin{aligned} \delta m_{\Xi}^{(a,e)} = & -8B(b_F - b_D)\bar{m}\varepsilon \frac{1}{16\pi^2 F_0^2} \left\{ (D-F)^2 m_{\pi}^2 \left(1 + 3 \ln \frac{\mu^2}{m_{\pi}^2} \right) \right. \\ & \left. + \frac{3D^2 - 2DF + 3F^2}{6} m_K^2 \left(1 + 3 \ln \frac{\mu^2}{m_K^2} \right) - \frac{m_s - \bar{m}}{36\bar{m}\varepsilon} (D-3F)^2 g_2(m_{K^0}, m_{K^+}) \right\} \\ & + 4B\bar{m}\varepsilon (b_D + b_F) \frac{D}{12\pi^2 F_0^2} \left\{ (D+F) \left(1 + 3 \ln \frac{\mu^2}{m_K^2} \right) - \frac{m_s - \bar{m}}{6\bar{m}\varepsilon} (D+3F) g_2(m_{K^0}, m_{K^+}) \right\}, \end{aligned} \quad (A2)$$

$$\begin{aligned} \delta m_{\Xi}^{(f)} = & -8B(b_F - b_D)\bar{m}\varepsilon \frac{1}{32\pi^2 F_0^2} \left\{ m_{\pi}^2 \left(1 + \ln \frac{\mu^2}{m_{\pi}^2} \right) + \frac{m_{\eta}^2}{3} \left(1 + \ln \frac{\mu^2}{m_{\eta}^2} \right) \right. \\ & \left. - \frac{\bar{m}}{m_s - m} \left(m_{\pi}^2 - m_{\eta}^2 + m_{\pi}^2 \ln \frac{\mu^2}{m_{\pi}^2} - m_{\eta}^2 \ln \frac{\mu^2}{m_{\eta}^2} \right) + m_K^2 \left(1 + \ln \frac{\mu^2}{m_K^2} \right) + \frac{m_s + \bar{m}}{2\bar{m}\varepsilon} g_1(m_{K^0}, m_{K^+}) \right\}. \end{aligned} \quad (A3)$$

The decuplet contribution to the Ξ mass splitting is

$$\begin{aligned} \delta m_{\Xi}^{(g,h)} = & B(b_D - b_F)\bar{m}\varepsilon \frac{C^2}{4\pi^2 F_0^2} \left[f_2(m_{\pi}, \Delta) + f_2(m_{\eta}, \Delta) + \frac{3}{2} f_2^+(m_K, \Delta) \right] \\ & + \frac{C^2}{2\pi^2 F_0^2} B[b_0(m_s + 2\bar{m}) + b_D(\bar{m} + m_s) + b_F(m_s - \bar{m})] \left\{ [f_2(m_{\pi}, \Delta) - f_2(m_{\eta}, \Delta)] \frac{\phi}{\sqrt{3}} - \frac{7}{12} f_2^-(m_K, \Delta) \right\} \end{aligned}$$

$$\begin{aligned}
& + \frac{b_C \mathcal{C}^2}{36\pi^2 F_0^2} B \bar{m} \varepsilon [f_2(m_\pi, \Delta) - 3f_2(m_\eta, \Delta) - 2f_2^+(m_K, \Delta)] \\
& + \frac{b_C \mathcal{C}^2}{6\pi^2 F_0^2} B \left\{ (2m_s + \bar{m}) \frac{\phi}{\sqrt{3}} [f_2(m_\pi, \Delta) - f_2(m_\eta, \Delta)] - \frac{2\bar{m} + 19m_s}{12} f_2^-(m_K, \Delta) \right\}. \tag{A4}
\end{aligned}$$

(ii) Σ . The recoil corrections to D and F and the couplings b_1 , b_2 , and b_3 give

$$\begin{aligned}
\delta m_\Sigma^{(a,b,c,d)} = & -2b_2 \frac{1}{8\pi^2 F_0^2} \left(m_{K^0}^4 - m_{K^+}^4 + m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) \\
& + b_2 \frac{1}{2\pi^2 F_0^2} \frac{\phi}{\sqrt{3}} \left(m_\pi^4 - m_\eta^4 + m_\pi^4 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^4 \ln \frac{\mu^2}{m_\eta^2} \right) \\
& - \frac{DF}{8\pi^2 F_0^2 m_B} \left(m_{K^0}^4 \ln \frac{\mu^2}{m_{K^0}^2} - m_{K^+}^4 \ln \frac{\mu^2}{m_{K^+}^2} \right) + \frac{DF}{4\pi^2 F_0^2 m_B} \frac{\phi}{\sqrt{3}} \left(m_\pi^4 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^4 \ln \frac{\mu^2}{m_\eta^2} \right). \tag{A5}
\end{aligned}$$

Loop corrections involving the operators b_D and b_F are

$$\begin{aligned}
\delta m_\Sigma^{(a,e)} = & B \bar{m} \varepsilon \frac{1}{12\pi^2 F_0^2} \left\{ 4[2b_D DF + b_F(D^2 + 3F^2)] m_\pi^2 \left(1 + 3 \ln \frac{\mu^2}{m_\pi^2} \right) \right. \\
& \left. + [2b_D DF + b_F(D^2 + F^2)] \left[6m_K^2 \left(1 + 3 \ln \frac{\mu^2}{m_K^2} \right) - 3g_2(m_{K^0}, m_{K^+}) \frac{m_s - \bar{m}}{\bar{m} \varepsilon} \right] \right\}, \\
\delta m_\Sigma^{(f)} = & B b_F \bar{m} \varepsilon \frac{1}{2\pi^2 F_0^2} \left\{ m_\pi^2 \left(1 + \ln \frac{\mu^2}{m_\pi^2} \right) + \frac{m_\eta^2}{3} \left(1 + \ln \frac{\mu^2}{m_\eta^2} \right) \right. \\
& \left. - \frac{\bar{m}}{m_s - \bar{m}} \left(m_\pi^2 - m_\eta^2 + m_\pi^2 \ln \frac{\mu^2}{m_\pi^2} - m_\eta^2 \ln \frac{\mu^2}{m_\eta^2} \right) + m_K^2 \left(1 + \ln \frac{\mu^2}{m_K^2} \right) + \frac{m_s + \bar{m}}{2\bar{m} \varepsilon} g_1(m_{K^0}, m_{K^+}) \right\}. \tag{A6}
\end{aligned}$$

The decuplet corrections are

$$\begin{aligned}
\delta m_\Sigma^{(g,h)} = & \frac{\mathcal{C}^2}{6\pi^2 F_0^2} B b_F \bar{m} \varepsilon [2f_2(m_\pi, \Delta) + 3f_2(m_\eta, \Delta) + 5f_2^+(m_K, \Delta)] \\
& - \frac{\mathcal{C}^2}{2\pi^2 F_0^2} B [b_0(m_s + 2\bar{m}) + 2\bar{m}b_D] \left\{ \frac{\phi}{\sqrt{3}} [f_2(m_\pi, \Delta) - f_2(m_\eta, \Delta)] - \frac{1}{2} f_2^-(m_K, \Delta) \right\} \\
& + \frac{b_C \mathcal{C}^2}{18\pi^2 F_0^2} B \bar{m} \varepsilon \left[f_2(m_\pi, \Delta) + 3f_2(m_\eta, \Delta) + \frac{11}{2} f_2^+(m_K, \Delta) \right] \\
& - \frac{b_C \mathcal{C}^2}{6\pi^2 F_0^2} B \left\{ (m_s + 2\bar{m}) \frac{\phi}{\sqrt{3}} [f_2(m_\pi, \Delta) - f_2(m_\eta, \Delta)] - \frac{7\bar{m} + 2m_s}{6} f_2^-(m_K, \Delta) \right\}. \tag{A7}
\end{aligned}$$

APPENDIX B: N²LO CORRECTIONS TO THE OCTET AVERAGE MASSES

In this appendix, we give the corrections to the nucleon, Ξ , Σ , and Λ average masses. To verify the relations involving the couplings $\bar{g}_{0\eta}$, $\bar{g}_{0N\Sigma K}$, and $\bar{g}_{0N\Lambda K}$, in addition to $\Delta^{(2)}m_N$, $\Delta^{(2)}m_\Sigma$, and $\Delta^{(2)}m_\Lambda$, one needs the octet baryon wave-function renormalization, the kaon and η meson wave function renormalization, and the corrections to F_K and F_η .

The corrections to the mesons wave function renormalization and decay constants are [42]

$$\delta Z_K = -\frac{m_\pi^2}{64\pi^2 F_0^2} (1 + L_\pi) - \frac{m_K^2}{32\pi^2 F_0^2} (1 + L_K) - \frac{m_\eta^2}{64\pi^2 F_0^2} (1 + L_\eta) - \frac{16B}{F_0^2} \left[(m_s + 2\bar{m})L_4 + \frac{1}{2}(m_s + \bar{m})L_5 \right], \tag{B1}$$

$$\delta Z_\eta = -\frac{m_K^2}{16\pi^2 F_0^2} (1 + L_K) - \frac{16B}{F_0^2} \left[L_4(m_s + 2\bar{m}) + \frac{1}{3}(2m_s + \bar{m})L_5 \right], \tag{B2}$$

$$\delta F_K = -\frac{3m_\pi^2}{128\pi^2 F_0^2}(1 + L_\pi) - \frac{3m_K^2}{64\pi^2 F_0^2}(1 + L_K) - \frac{3m_\eta^2}{128\pi^2 F_0^2}(1 + L_\eta) - \frac{8B}{F_0^2} \left[(m_s + 2\bar{m})L_4 + \frac{1}{2}(m_s + \bar{m})L_5 \right], \quad (\text{B3})$$

$$\delta F_\eta = -\frac{3m_K^2}{32\pi^2 F_0^2}(1 + L_K) - \frac{8B}{F_0^2} \left[(m_s + 2\bar{m})L_4 + \frac{1}{3}(2m_s + \bar{m})L_5 \right], \quad (\text{B4})$$

where we have introduced the shorthand $L_i = \ln \mu^2/m_i^2$, for $i = \{\pi, K, \eta\}$, to make the formulas in this appendix more compact.

Then we give the corrections to the baryon octet masses and wave function renormalization. The result of Figs. 2(a)–2(f), which involve octet intermediate states, agree with Ref. [65,75]. The decuplet corrections agree with the results of Ref. [65]. We also agree with Ref. [69], after we expand in Δ , and set the light-quark mass \bar{m} to zero, as was done in Ref. [69].

- (i) *Nucleon*. The nucleon wave function renormalization is given in Eq. (85). The loop contributions to the nucleon mass, including decuplet corrections, are

$$\begin{aligned} \Delta m_N = & \frac{1}{96\pi^2 F_0^2 m_B} \left[(5D^2 - 6DF + 9F^2)m_K^4 L_K + \frac{9}{2}(D + F)^2 m_\pi^4 L_\pi + (D - 3F)^2 \frac{m_\eta^4}{2} L_\eta \right] \\ & + \frac{1}{48\pi^2 F_0^2} [6(3b_1 - b_2 + 3b_3 + 4b_8)m_K^4(1 + L_K) \\ & + (9b_1 - 3b_2 + b_3 + 6b_8)m_\eta^4(1 + L_\eta) + 9(b_1 + b_2 + b_3 + 2b_8)m_\pi^4(1 + L_\pi)] \\ & - B(m_s - \bar{m}) \frac{m_K^2}{72\pi^2 F_0^2} [(13D^2 - 30DF + 9F^2)b_D - 3(5D^2 - 6DF + 9F^2)b_F] \\ & \times (1 + 3L_K) - B(m_s + \bar{m}) \frac{m_K^2}{8\pi^2 F_0^2} (4b_0 + 3b_D - b_F)(1 + L_K) \\ & - 3B\bar{m} \frac{m_\pi^2}{8\pi^2 F_0^2} (2b_0 + b_D + b_F)(1 + L_\pi) - B \frac{m_\eta^2}{24\pi^2 F_0^2} [4m_s(b_0 + b_D - b_F) + \bar{m}(2b_0 + b_D + b_F)](1 + L_\eta) \\ & - B \frac{\mathcal{C}^2}{8\pi^2 F_0^2} [(2b_0 + b_D + b_F)\bar{m} + (b_0 + b_D - b_F)m_s] [4f_2(m_\pi, \Delta) + f_2(m_K, \Delta)] \\ & - B \frac{b_C \mathcal{C}^2}{24\pi^2 F_0^2} [(2\bar{m} + m_s)f_2(m_K, \Delta) + 12\bar{m}f_2(m_\pi, \Delta)]. \end{aligned} \quad (\text{B5})$$

The counterterm operators in $\mathcal{L}^{(4)}$ give

$$\begin{aligned} \frac{\Delta^{(\text{ct})} m_N}{(4B)^2} = & -[(d_1 - d_2 + d_3 - d_5 + d_6 + d_7 + d_8)m_s^2 - (2d_1 - 2d_3 + d_5 - 3d_6 - 4d_7)\bar{m}m_s \\ & + (d_1 + d_2 + d_3 + 2d_5 + 2d_6 + 4d_7 + 2d_8)\bar{m}^2]. \end{aligned} \quad (\text{B6})$$

- (ii) Ξ . The wave function renormalization of the Ξ field, in the isospin limit, is

$$\begin{aligned} \delta Z_\Xi = & (5D^2 + 6DF + 9F^2) \frac{m_K^2}{96\pi^2 F_0^2} (1 + 3L_K) + (D + 3F)^2 \frac{m_\eta^2}{192\pi^2 F_0^2} (1 + 3L_\eta) \\ & + 3(D - F)^2 \frac{m_\pi^2}{64\pi^2 F_0^2} (1 + 3L_\pi) + \frac{\mathcal{C}^2}{32\pi^2 F_0^2} [3f_2(m_K, \Delta) + f_2(m_\eta, \Delta) + f_2(m_\pi, \Delta)]. \end{aligned} \quad (\text{B7})$$

The loop contributions to the Ξ mass, including decuplet corrections, are

$$\begin{aligned} \Delta m_\Xi = & \frac{1}{96\pi^2 F_0^2 m_B} \left[(5D^2 + 6DF + 9F^2)m_K^4 L_K + \frac{9}{2}(D - F)^2 m_\pi^4 L_\pi + (D + 3F)^2 \frac{m_\eta^4}{2} L_\eta \right] \\ & + \frac{1}{48\pi^2 F_0^2} [6(3b_1 + b_2 + 3b_3 + 4b_8)m_K^4(1 + L_K) + (9b_1 + 3b_2 + b_3 + 6b_8)m_\eta^4(1 + L_\eta) \\ & + 9(b_1 - b_2 + b_3 + 2b_8)m_\pi^4(1 + L_\pi)] - B(m_s - \bar{m}) \frac{m_K^2}{72\pi^2 F_0^2} [(13D^2 + 30DF + 9F^2)b_D \end{aligned}$$

$$\begin{aligned}
& + 3(5D^2 + 6DF + 9F^2)b_F(1 + 3L_K) - B(m_s + \bar{m})\frac{m_K^2}{8\pi^2 F_0^2}(4b_0 + 3b_D + b_F)(1 + L_K) \\
& - 3B\bar{m}\frac{m_\pi^2}{8\pi^2 F_0^2}(2b_0 + b_D - b_F)(1 + L_\pi) - B\frac{m_\eta^2}{24\pi^2 F_0^2}[4m_s(b_0 + b_D + b_F) + \bar{m}(2b_0 + b_D - b_F)](1 + L_\eta) \\
& - B\frac{\mathcal{C}^2}{8\pi^2 F_0^2}[(2b_0 + b_D - b_F)\bar{m} + (b_0 + b_D + b_F)m_s][f_2(m_\pi, \Delta) + f_2(m_\eta, \Delta) + 3f_2(m_K, \Delta)] \\
& - B\frac{b_C \mathcal{C}^2}{24\pi^2 F_0^2}\{(\bar{m} + 2m_s)[f_2(m_\pi, \Delta) + f_2(m_\eta, \Delta)] + (7m_s + 2\bar{m})f_2(m_K, \Delta)\}. \tag{B8}
\end{aligned}$$

The counterterm operators in $\mathcal{L}^{(4)}$ give

$$\begin{aligned}
\frac{\Delta^{(c)}m_\Xi}{(4B)^2} &= -[(d_1 + d_2 + d_3 + d_5 + d_6 + d_7 + d_8)m_s^2 - (2d_1 - 2d_3 - d_5 - 3d_6 - 4d_7)\bar{m}m_s \\
& + (d_1 - d_2 + d_3 - 2d_5 + 2d_6 + 4d_7 + 2d_8)\bar{m}^2]. \tag{B9}
\end{aligned}$$

(iii) Σ . The wave function renormalization of the Σ field, in the isospin limit, is

$$\begin{aligned}
\delta Z_\Sigma &= (D^2 + F^2)\frac{m_K^2}{16\pi^2 F_0^2}(1 + 3L_K) + (D^2 + 6F^2)\frac{m_\pi^2}{48\pi^2 F_0^2}(1 + 3L_\pi) \\
& + D^2\frac{m_\eta^2}{48\pi^2 F_0^2}(1 + 3L_\eta) + \frac{\mathcal{C}^2}{32\pi^2 F_0^2}\left[\frac{10}{3}f_2(m_K, \Delta) + f_2(m_\eta, \Delta) + \frac{2}{3}f_2(m_\pi, \Delta)\right]. \tag{B10}
\end{aligned}$$

The loop contributions to the Σ mass, including decuplet corrections, are

$$\begin{aligned}
\Delta m_\Sigma &= \frac{1}{48\pi^2 F_0^2 m_B}\left[3(D^2 + F^2)m_K^4 L_K + (D^2 + 6F^2)m_\pi^4 L_\pi + D^2 m_\eta^4 L_\eta\right] \\
& + \frac{1}{24\pi^2 F_0^2}\left[6(b_1 + b_3 + 2b_8)m_K^4(1 + L_K) + (2b_3 + 3b_8)m_\eta^4(1 + L_\eta) + 3(4b_1 + 2b_3 + 3b_8)m_\pi^4(1 + L_\pi)\right] \\
& + B(m_s - \bar{m})\frac{m_\pi^2}{9\pi^2 F_0^2}b_D D^2(1 + 3L_\pi) + B(m_s - \bar{m})\frac{m_K^2}{4\pi^2 F_0^2}[(D^2 + F^2)b_D + 2DFb_F](1 + 3L_K) \\
& - B(m_s + \bar{m})\frac{m_K^2}{4\pi^2 F_0^2}(2b_0 + b_D)(1 + L_K) - 3B\bar{m}\frac{m_\pi^2}{4\pi^2 F_0^2}(b_0 + b_D)(1 + L_\pi) \\
& - B\frac{m_\eta^2}{12\pi^2 F_0^2}[\bar{m}b_D + b_0(2m_s + \bar{m})](1 + L_\eta) - B\frac{\mathcal{C}^2}{24\pi^2 F_0^2}[2(b_0 + b_D)\bar{m} + b_0 m_s][2f_2(m_\pi, \Delta) + 3f_2(m_\eta, \Delta) \\
& + 10f_2(m_K, \Delta)] - B\frac{b_C \mathcal{C}^2}{72\pi^2 F_0^2}\{(2\bar{m} + m_s)[2f_2(m_\pi, \Delta) + 3f_2(m_\eta, \Delta)] + 2(2m_s + 13\bar{m})f_2(m_K, \Delta)\}. \tag{B11}
\end{aligned}$$

The counterterm operators in $\mathcal{L}^{(4)}$ give

$$\frac{\Delta^{(c)}m_\Sigma}{(4B)^2} = -[(d_7 + d_8)m_s^2 + 2(d_6 + 2d_7)\bar{m}m_s + (4d_3 + 4d_6 + 4d_7 + 2d_8)\bar{m}^2]. \tag{B12}$$

(iv) Λ . The wave function renormalization of the Λ field, in the isospin limit, is

$$\begin{aligned}
\delta Z_\Lambda &= (D^2 + 9F^2)\frac{m_K^2}{48\pi^2 F_0^2}(1 + 3L_K) + D^2\frac{m_\pi^2}{16\pi^2 F_0^2}(1 + 3L_\pi) + D^2\frac{m_\eta^2}{48\pi^2 F_0^2}(1 + 3L_\eta) \\
& + \frac{\mathcal{C}^2}{32\pi^2 F_0^2}[2f_2(m_K, \Delta) + 3f_2(m_\pi, \Delta)]. \tag{B13}
\end{aligned}$$

The loop contributions to the Λ mass, including decuplet corrections, are

$$\begin{aligned}
\Delta m_\Lambda = & \frac{1}{48\pi^2 F_0^2 m_B} [(D^2 + 9F^2)m_K^4 L_K + 3D^2 m_\pi^4 L_\pi + D^2 m_\eta^4 L_\eta] \\
& + \frac{1}{24\pi^2 F_0^2} [2(9b_1 + b_3 + 6b_8)m_K^4(1 + L_K) + 3(2b_3 + b_8)m_\eta^4(1 + L_\eta) + 3(2b_3 + 3b_8)m_\pi^4(1 + L_\pi)] \\
& - B(m_s - \bar{m}) \frac{m_\pi^2}{3\pi^2 F_0^2} (b_D D^2)(1 + 3L_\pi) - B(m_s - \bar{m}) \frac{m_K^2}{36\pi^2 F_0^2} [(D^2 + 9F^2)b_D + 18DFb_F](1 + 3L_K) \\
& - B(m_s + \bar{m}) \frac{m_K^2}{12\pi^2 F_0^2} (6b_0 + 5b_D)(1 + L_K) - B\bar{m} \frac{m_\pi^2}{4\pi^2 F_0^2} (3b_0 + b_D)(1 + L_\pi) \\
& - B \frac{m_\eta^2}{36\pi^2 F_0^2} [(\bar{m} + 8m_s)b_D + 3b_0(2m_s + \bar{m})](1 + L_\eta) - B \frac{\mathcal{C}^2}{24\pi^2 F_0^2} [3b_0(2\bar{m} + m_s) + 2b_D(\bar{m} + 2m_s)] \\
& \times [3f_2(m_\pi, \Delta) + 2f_2(m_K, \Delta)] - B \frac{b_C \mathcal{C}^2}{24\pi^2 F_0^2} [(2\bar{m} + m_s)3f_2(m_\pi, \Delta) + 2(2m_s + \bar{m})f_2(m_K, \Delta)]. \quad (\text{B14})
\end{aligned}$$

The counterterm operators in $\mathcal{L}^{(4)}$ give

$$\frac{\Delta^{(\text{ct})} m_\Lambda}{(4B)^2} = -\frac{1}{3} \{ [8d_3 + 2d_4 + 4d_6 + 3(d_7 + d_8)]m_s^2 + 2(-2d_4 + 5d_6 + 6d_7)\bar{m}m_s + 2(2d_3 + d_4 + 2d_6 + 6d_7 + 3d_8)\bar{m}^2 \}. \quad (\text{B15})$$
