34 **Abstract**

35 There is increasing evidence about the use of oncolytic adenoviruses (Ads) as
36 promising immunotherapy agents. We have previously demonstrated the clinical
37 efficiency of mesenchymal stem cells (MSCs) infected with oncolytic Ads as an
38 antitumoral immunotherapy (called Celyvir) in human and canine patients, using
39 ICOVIR-5 or ICOCAV17 as human and canine oncolytic Ads, respectively.
40 Considering the better clinical outcomes of canine patients, in this study we
41 searched for differences in cellular responses of human and canine MSCs to Ad
42 infection that may help understand the mechanisms leading to higher antitumor
43 immune response. We found that infection of human and canine MSCs with
44 ICOVIR-5 or ICOCAV17 did not activate the NF- κ B pathway or the interferon
45 regulatory factors IRF3 and IRF7. However, we observed differences in the profile
46 of cytokines secretion, as infection of canine MSCs with ICOCAV17 resulted in
47 lower secretion of several cytokines. Moreover, we showed that infection of
48 human MSCs with ICOVIR-5 increased the phosphorylation of a number of
49 proteins, including AKT and cJUN. Finally, we demonstrated that differences in
50 regulation of AKT and cJUN in human and canine MSCs by ICOVIR-5 or
51 ICOCAV17 are intrinsic to each virus. Our findings suggest that ICOCAV17
52 induces a more limited host response in canine MSCs, which may be related to
53 a better clinical outcome. This result opens the possibility to develop new human
54 oncolytic Ads with these specific properties. In addition, this improvement could
55 be imitated by selecting specific human MSC on the basis of a limited host
56 response after Ad infection.

58 AKT, JUN

59 **Introduction**

60 The use of oncolytic viruses is an immunotherapy treatment for cancer that uses
61 viruses designed to infect and/or replicate specifically in tumor cells. Recently,
62 Imlygic, an oncolytic virus based in herpes virus, received the approval from the
63 FDA and EMA to be used intratumorally in melanoma patients (1). However, very
64 limited efficacy has been observed in clinical studies using intravenous delivery
65 of oncolytic viruses. With the aim to target metastatic or widespread cancer we
66 have developed a “Trojan horse” strategy using cellular-vehicles to deliver
67 oncolytic virus intravenously. In this regard, we have previously demonstrated the
68 efficiency of mesenchymal stem cells (MSCs) infected with oncolytic
69 adenoviruses (Ads) as an antitumoral immunotherapy that we called Celyvir.
70 Thus, we reported an initial clinical experience of this treatment related with a
71 program of compassionate use and a clinical trial in pediatric patients
72 (NCT01844661) showing an excellent toxicity profile and several clinical
73 responses, including two complete remissions (2-4). More recently, we improved
74 our immunotherapy in mice models (5, 6) and finally we tested these
75 improvements in dogs with spontaneous tumors in a veterinary clinical trial (7).
76 Naturally occurring cancers in pet dogs and humans share many features,
77 including histological appearance, tumor genetics, molecular targets, biological
78 behavior and response to conventional therapies (8). Thus, in our veterinary trial
79 including 27 canine patients treated with dCelyvir, we used dog MSCs (dMSCs)
80 infected with ICOCV17 –a canine adenovirus homologous to human ICVIR-
81 5– and we observed a clinical benefit in 74% of patients, including 14.8% showing
82 complete remissions (7).

83 Although we have demonstrated the clinical efficacy of Celyvir, it is
84 necessary to further explore its mechanism of action to improve its benefits. The
85 basic elements of Ad intracellular trafficking have been described although
86 differences have been noted related with variations based on Ad serotype, target
87 cell type, and cell physiology (9). In non-immune cells, signalling events activated
88 by Ad infection are relatively well studied (e.g., PI3K, p38, ERK and NF- κ B) and
89 although these cells may contribute to certain Ad innate reactions, the majority of
90 these responses are originated from cells of the innate immune system such as
91 macrophages and dendritic cells (10). This associated immune response is also
92 influenced by the virus type, cell type and host species (11) and includes:
93 activation of a systemic pro-inflammatory state, attracting cytotoxic immune cell
94 populations to the sites of infection to eliminate virus-containing cells, and
95 alarming neighboring uninfected cells of viral infection (12).

96 Several groups have observed specific effects after transduction of human
97 cells with human and canine adenoviral vectors (13, 14). Here we compared the
98 effects of human MSCs (hMSCs) infected with ICOVIR-5 in signaling pathways
99 to those of dMSCs infected with ICOCV17. Considering the better clinical
100 outcomes of dCelyvir, the observed differences have the potential to help
101 understand the mechanisms leading to increase the clinical efficacy of Celyvir.

102

103 **Materials and methods**

104 **Cell lines and cell culture.** hMSCs were purchased from Lonza (Basel,
105 Switzerland) and cultured either in Mesenchymal Stem Cell Growth Medium
106 (MSCGM) and the necessary supplements or in Dulbecco's Modified Eagle's
107 Media (DMEM) supplemented with heat-inactivated 10% fetal bovine serum

108 (FBS), 2 mM glutamine, streptomycin (100 mg/mL) and penicillin (100 U/mL)
109 (complete DMEM). dMSCs and the DK28Cre cell line were obtained as indicated
110 in (7) and cultured in complete DMEM. HEK293 cells were cultured in complete
111 DMEM. All cell lines were maintained under standard conditions (5% CO₂, 37°C)
112 in their appropriate medium and routinely tested for mycoplasma contamination
113 using the MycoAlert Micoplasm Detection Kit (Lonza). All culture reagents were
114 obtained from Lonza with the exception of FBS, which was purchased from Sigma
115 (St. Louis, MO, USA).

116 **Adenovirus.** ICOVIR-5 and ICOCV17 have been extensively described
117 elsewhere (15, 16), respectively. CAV2-GFP is a canine non replicative
118 adenoviral vector expressing GFP and was purchased from the Viral Vector
119 Production Unit at Universitat Autònoma de Barcelona, Spain. All Ads were
120 generated by the transfection of linearized plasmid into HEK293 (ICOVIR-5) or
121 DK28Cre cells (ICOCV17 and CAV2-GFP) and purified by CsCl gradient
122 centrifugation.

123 **Infection of MSCs, HEK293 and DK28Cre.** Unless otherwise stated, MSCs
124 were infected at different multiplicity of infection (MOI) in serum-free DMEM for
125 2h at 37°C, washed with PBS, seeded and incubated in complete DMEM at 37°C
126 for the required time points. For analysis of viral production, human and canine
127 MSCs were infected with ICOVIR-5 and ICOCV17 for three days, then cells
128 and medium were harvested and the virus particles released by three repeated
129 freeze-thaw cycles. Cell debris were removed by centrifugation at 1200 rpm for
130 5 min and filtered through a 0.45 µm filter. Then, HEK293 cells (for amplification
131 of ICOVIR-5) or DK28Cre cells (for amplification of ICOCV17) were seeded in
132 24-well plates and infected with the appropriate cell-free extract. Cells were

133 examined every day for cytopathic effects using a Leica DM IL LED microscope
134 (Leica Microsystems, Wetzlar, Germany). CAV2-GFP infected cells were
135 analyzed using the Leica TCS SP5 multispectral confocal microscope (Leica
136 Microsystems) and representative images were obtained by maximum projection
137 of 4 stacks.

138 **Quantitation of viral DNA by qPCR.** ICOVIR-5 and ICOCV17 genome copy
139 number was quantified by Quantitative Real Time-PCR as previously described
140 (17). Briefly, total DNA from cell culture supernatants was isolated by the QIAamp
141 DNA Mini Kit (QIAGEN, Valencia, CA) according to the manufacturer's
142 instructions. Five microliters of DNA were used for Real Time-PCR using the
143 primers ICO5F2: GAT TTG GCG CGT AAA AGT G and ICO5R2: CGG CCA TTT
144 CTT CGG TAA TA for ICOVIR-5 and CAV2-F: CGT GAA GCG CCG TAG ATG
145 C and CAV2-R: GAA CCA GGG CGG GAG ACA AGT ATT for ICOCV17. Real
146 Time PCR consisting of 10 min at 95°C and 40 cycles (95°C, 10 s; 60°C 10 s;
147 72°C, 18 s) was performed on the LightCycler 1.5 Real Time PCR Thermal Cycler
148 (Roche, Basel, Switzerland), using LightCycler FastStart Essential DNA Green
149 Master (Roche) and analyzed with LightCycler Software 3.5 (Roche). A qPCR
150 standard curve was generated using 10-fold serial dilutions of ICOVIR-5 and
151 ICOCV17 plasmid DNA and the copy number present in the sample was
152 obtained by extrapolation of the Ct value on the standard curve. Two independent
153 experiments with different MSC donors were performed.

154 **Luciferase assays.** The activation of NF-κB pathway was determined using a
155 luciferase reporter system (18). Replication incompetent lentiviral vectors were
156 created using the pHAGE NF-κB-TA-LUC-UBC-GFP-W plasmid, a gift from
157 Darrell Kotton (Addgene plasmid #49343). The plasmid encodes the NF-κB

158 consensus binding sequence upstream of the minimal TA promoter of the herpes
159 simplex virus followed by the firefly luciferase gene as well as the eGFP gene
160 upstream of the ubiquitin-C promoter. Transduction of MSCs was performed
161 overnight and GFP expression was assessed by flow cytometry. For luciferase-
162 reporter assays, control and adenovirus infected cells were lysed and luciferase
163 activity was assayed with the Luciferase Assay System (Promega, Madison, WI,
164 USA) according to the manufacturer's instructions. Three independent
165 experiments with different MSC donors were performed.

166 **Western blot analysis.** Total proteins were extracted with SDS sample buffer
167 (62.5 mM Tris pH 6.8, 2% SDS, 10% glycerol, 1 mM phenylmethylsulfonyl fluoride
168 [PMSF], 5 mM NaF, 20 mM β -glycerophosphate, 0.1 mM Na_3VO_4 , and 1:100
169 protease inhibitor cocktail from Sigma). Then, samples were boiled and
170 sonicated. Nuclear extracts were prepared using the Nuclear Extraction Kit
171 (Abcam, *Cambridge*, UK) according to the manufacturer's instructions. Primary
172 antibodies were mouse monoclonal anti-c-Jun (phospho S63) 1:1000 dilution
173 (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA), rabbit monoclonal anti-
174 AKT1 (phospho S473) antibody, 1:1000 dilution (Epitomics, Burlingame, CA,
175 USA), rabbit polyclonal anti-RelB 1:200 dilution (Santa Cruz Biotechnology Inc.),
176 rabbit polyclonal anti-I κ B- α 1:200 dilution (Santa Cruz Biotechnology Inc.), and
177 mouse monoclonal anti- β -actin, 1:100000 dilution (Sigma). Secondary antibodies
178 were polyclonal goat anti-rabbit and anti-mouse immunoglobulins/HRP, 1:3000
179 dilution (DAKO, Carpinteria, CA, USA). Two independent experiments with
180 different MSC donors were performed.

181 **Cytokine and phospho-kinase array analysis.** For the analysis of the cytokine
182 pattern in both hMSCs and dMSCs after adenovirus infection, the Human XL

183 Cytokine Array kit (R&D Systems, Minneapolis, MN, USA) was used according
184 to manufacturer's recommendation. The array consisted of 102 different human
185 cytokine antibodies spotted in duplicate onto a nitrocellulose membrane. hMSCs
186 and dMSCs from two different donors were first seeded on 6-well dishes at a
187 density of 10^5 and 2×10^5 cells/well, respectively. Then, they were infected for 1.5
188 h, washed with PBS and incubated in serum-free DMEM for 3 h or 24 h. Finally,
189 supernatants from either control or adenovirus infected samples were collected,
190 centrifuged to eliminate dead cells and debris and the protein pattern was
191 analyzed using proteome profiler array kits. The phosphorylation profile in MSCs
192 after adenovirus infection was analyzed using the Proteome Profiler Human
193 Phospho-Kinase Array (R&D Systems) according to the manufacturer's
194 instructions. This array detects phosphorylation of 43 human kinases and total
195 amounts of 2 related proteins. Cell lysates (400 μ g) from either control or
196 adenovirus infected samples were incubated with each set of nitrocellulose
197 membranes of the Human Phospho-Kinase Array with the spotted capture
198 antibodies. Array images were scanned and digitized, and integrated pixel
199 density of the spots was quantified using the Fiji software. The average density
200 of duplicated spots representing each protein was used to determine changes in
201 expression of cytokines or phosphorylated proteins after adenoviral infection.
202 Differentially expressed proteins were further studied with STRING software (19)
203 to analyze the biological process and reactome pathways in which they are
204 involved.

205 **Statistical analysis.** Data was analyzed and graphed using GraphPad Prism
206 (GraphPad Software, San Diego, CA, USA). Statistical significance was

207 determined using unpaired t-test: $p < 0.05$ (*), $p < 0.01$ (**), $p < 0.001$ (***) and p
208 < 0.0001 (****).

209

210 **Results**

211 **Infection of MSCs with ICOVIR-5 and ICOCV17 does not activate either NF-** 212 **κ B pathway or interferon regulatory factors IRF3 and IRF7**

213 In order to compare the effects of ICOVIR-5 and ICOCV17 infection of hMSCs
214 and dMSCs, respectively, we first studied the sensitivity of both cells to each Ad.
215 For the clinical trial of hCelyvir, ICOVIR-5 was used at a MOI of 200 PFU/cell
216 because that was the average MOI obtained in previous studies for the infection
217 of hMSCs from different donors (4). For our veterinary trial of dCelyvir (7), we
218 used ICOCV17 at a MOI of 1 PFU/cell based in previous results using this
219 oncolytic Ads, where the IC50 values infecting canine tumoral cell lines ranked
220 0,5-15 PFU/cell (16). Thus, we compared hMSCs and dMSCs infected at these
221 MOIs and observed that they were infected to an equivalent degree
222 (Supplementary Fig. S1). First, Ad infection caused similar cytopathic effects
223 (CPE), which started at 2 days post-infection. In addition, Ad titers obtained from
224 supernatant cultures were comparable (Fig. 1a). However, when hMSCs were
225 infected at 1 PFU/cell no detectable CPE was observed whereas infection of
226 dMSCs at 200 PFU/cell caused excessive early CPE (Supplementary Fig. S1).
227 Therefore, as our goal was to compare Ad-induced effects in MSCs in hCelyvir
228 and dCelyvir under clinical conditions (healthy MSCs able to undergo tumor-
229 homing during 24-48 h post-infection), we performed all the experiments under
230 the conditions previously published.

231 Ad infection leads to the activation of intracellular signaling cascades as a
232 virus-induced innate response of the cells (10). We first searched for Ad-induced
233 differences in immune-related pathways in hMSCs and dMSCs. Because NF- κ B
234 is classically activated by Ads and activates numerous early response genes,
235 including genes encoding for inflammatory cytokines and chemokines (20), we
236 studied its activation using a lentiviral vector expressing a luciferase reporter
237 gene under a NF- κ B promoter. No significant differences in luciferase levels were
238 observed at the times studied in either type of cell (Fig.1a, b). Similarly,
239 immunoblotting experiments revealed that proteins involved in the induction of
240 the canonical (I κ B- α) and non-canonical (RelB) NF- κ B pathways as well as
241 interferon regulatory factors IRF3 and IRF7, which activate the transcription of
242 IFN- α or IFN- β , respectively, were constitutively expressed at similar levels in
243 infected cells compared to the control (Fig. 1c-f). Nevertheless, we observed a
244 slight decrease in I κ B- α in hMSCs after 24 hours of infection consistent with the
245 small increase in luciferase levels shown in Fig.1a.

246 **Analysis of cytokines in MSCs displays different secretion profiles**

247 Next, we investigated the profiles of cytokine secretion in MSCs in response to
248 Ad infection using a human cytokine antibody array, as other human arrays have
249 been successfully used in the analysis of canine samples (21). Overall, a more
250 complex profile was detected at 3 hours post-infection compared to 24 hours.
251 Thus, at 3 hours, signal above background level was detected in hMSCs for all
252 105 cytokines implemented in the array compared with 71 in dMSCs (Fig. 2a).
253 However, after 24 hours, signal was detected only for 41 cytokines in hMSCs
254 compared with 19 in dMSCs (Fig. 2b). When we compared ICOVIR-5-infected
255 hMSCs to ICOCAV17-infected dMSCs, no major differences were found on the

256 levels of secreted cytokines. Thus, the array included well characterized pro-
257 inflammatory cytokines (IL-1, IL-6, IL-8, IL-12, IFN- γ , IL-18, and TNF) whose
258 analysis showed no significant differences between infected and control samples
259 (Fig. 2a-b). This is consistent with the lack of activation of NF- κ B pathway
260 observed above (Fig. 1a-d). Nevertheless, there were significant differences in
261 fold-change of four cytokines (ST2, TARC, THBS1 and μ PAR) after Ad-infection,
262 showing a higher down-regulated expression in ICOCV17-infected dMSCs
263 compared to ICOVIR-5-infected hMSCs (Fig. 2c, d).

264 **AKT and JUN are differentially regulated in hMSCs and dMSCs after** 265 **infection with ICOVIR-5 and ICOCV17**

266 To determine whether other signaling pathways were altered by Ad infection in
267 MSCs, since Ad-induced phosphorylation of several proteins is well described
268 (10), we utilized a human phospho-kinase array to detect changes in
269 phosphorylation profiles of kinases and their substrates. hMSCs and dMSCs
270 were infected with ICOVIR-5 and ICOCV17 and phosphorylation profiles
271 analyzed at 3 and 24 hours postinfection (Fig. 3a, b). Analysis of phosphorylation
272 profiles in ICOVIR-5-infected hMSCs compared to ICOCV17-infected dMSCs
273 resulted in some significant changes at 3 and 24 hours postinfection (Fig. 3c, d)
274 although the differences observed were very small in most cases (especially at 3
275 hours). However, after 24 hours, ICOVIR-5 and ICOCV17 infection of hMSCs
276 and dMSCs resulted in strong contrasting effects on the phosphorylation levels
277 of AKT (fold change: 33.3 in hMSCs compared to -0.3 in dMSCs) and c-JUN (fold
278 change: 1.4 in hMSC compared to -1 in dMSCs). Similar significant results were
279 observed for GSK-3 α/β and CREB. Considering the well-known roles of the AKT
280 and c-JUN pathways during Ad infection (10), we further validated the expression

281 of both proteins in different donors using western blot analysis (Supplementary
282 Figure S2). Consistent with the results from the array, phosphorylation of both
283 AKT and c-JUN in hMSCs infected with ICOVIR-5 increased at 24 hours
284 postinfection. In contrast, none pathway was activated in dMSCs infected with
285 ICOCV17. In both cases the observed changes were dose dependent.

286 STRING analysis depicted networks of interactions of the significantly
287 higher secreted cytokines and phosphorylated proteins in infected hMSC
288 compared to infected dMSC at 3 hours (Fig. 3e) and 24 hours (Fig. 3f). Gene
289 Ontology enrichment analyses identified biological processes that are associated
290 with positive regulation of cellular process, negative regulation of cell death,
291 regulation of apoptosis and regulation of autophagy.

292 **Regulation of AKT and JUN in hMSCs and dMSCs by ICOVIR-5 or ICOCV17** 293 **infection is intrinsic to each specific adenovirus**

294 Considering the contrasting differences observed between human and canine
295 Ads in AKT and c-JUN phosphorylation, we further tested whether these
296 responses were host- or Ad-specific. We then performed host-cross infections of
297 human and canine adenoviruses (Fig. 4a). We found out that ICOVIR-5 was able
298 to replicate in some degree in dMSCs, as a strong CPE was observed in
299 HEK293 cells infected with virus released from ICOVIR-5-infected dMSCs (Fig.
300 4a-II). In addition, Ad titers were similar to those obtained for ICOVIR-5-infected
301 hMSCs (Fig. 4b). By contrast, ICOCV17 infection of hMSCs was very
302 inefficient as the CPE caused to DK28Cre cells infected with virus released from
303 ICOCV17-infected hMSCs was very weak (Fig. 4a-IV) and Ad titers were very
304 low (Fig. 4b). Indeed, when hMSCs were infected with CAV2-GFP, a non-
305 replicative canine Ad vector, no fluorescence was observed whereas infection

306 of dMSCs resulted in strong GFP signal (Fig. 4c). Finally, infection of dMSCs
307 with human ICOVIR-5 resulted in a strong phosphorylation of AKT and c-JUN
308 similar to ICOVIR-5-infected hMSCs but no activation of AKT and c-JUN was
309 observed when hMSCs were infected with ICOCVAV17 (Fig. 4d).

310

311 **Discussion**

312 The aim of this study was to identify specific responses induced by ICOVIR-5 and
313 ICOCVAV17, human and canine oncolytic Ads respectively, upon infection of
314 MSCs that may be related to the better clinical outcome of dCelyvir. Other studies
315 using human cells infected by human and canine Ads have identified specific
316 responses of each virus (13, 14). By contrast, we searched for differences
317 between ICOVIR-5-infected hMSCs and ICOCVAV17-infected dMSC. Our data
318 suggest that NF- κ B pathway, interferons and pro-inflammatory cytokine secretion
319 are not the primary sensors of Ad infection in hMSCs and dMSCs. Similarly, it
320 has been shown that transduction of rat MSCs with human adenoviral vectors
321 has no major influence on the expression profile of immunologically relevant
322 parameters (22). Although we observed distinct cytokine secretion profiles, part
323 of the differences observed in our non-infected samples may be due to lack of
324 homology between human and canine cytokines. Nevertheless, we demonstrated
325 that hMSCs and dMSCs displayed Ad-induced changes in the secretion of ST2,
326 TARC, THBS1 and μ PAR. These differences found were mostly due to
327 decreased secretion in dCelyvir, not by higher secretion in hCelyvir (with the
328 exception of TARC). Thus, the decrease of these cytokines, together with the
329 overall reduction of cytokine secretion after 24 hours in dMSCs indicates that
330 dCelyvir presents a lower profile of cytokine expression.

331 Interestingly, when we compared the activation of other important
332 signaling molecules, a number of differentially phosphorylated targets were
333 identified. It is known that many viruses modulate the signaling pathways of the
334 host cell to escape activation of key innate immune mechanisms and establish a
335 productive infection (23). Thus, some viruses activate PI3K–AKT signaling for
336 latent infection and others for short-term cellular survival during the initial stages
337 of acute infection, when virus replication and protein synthesis are taking place
338 (24). Accordingly, our findings that ICOVIR-5 induces a strong phosphorylation
339 of AKT and c-JUN in hMSCs after 24 hours of infection whereas ICOCV17 does
340 not activate these pathways in dMSCs, indicate that ICOCV17 induces a more
341 limited host response than ICOVIR-5. The fact that ICOVIR-5, a human Ad, can
342 also activate AKT and c-JUN in canine MSCs demonstrates that these cells can
343 activate these pathways in response to other Ads. These data indicate that the
344 impaired cellular signaling after infection is intrinsic to ICOCV17. Together with
345 the observed decreased cytokine secretion, the results suggest that ICOCV17
346 somehow avoids host cell signaling in dMSCs.

347 Activation of PI3K/AKT and AP-1 signaling pathways by Ads is well
348 established, and the roles of these pathways in cell survival and apoptosis are
349 known. Remarkably, Ad activation of the PI3K/AKT pathway maintains host cell
350 viability during viral replication and therefore benefits the virus rather than the
351 host (25). Moreover, activation of JUN kinases and AKT has been proposed to
352 be required for Ad-mediated autophagy necessary for their lytic cycle, using
353 □24RGD, an Ad very similar to ICOVIR-5 (26). Binding of the Ad penton base
354 RGD-motif to α_v integrins induces phosphorylation of several signaling proteins,
355 including FAK and PI3K (27), but canine Ads do not contain a RGD motif in their

356 penton base, using the Coxsackie and Ad receptor (CAR) or other primary
357 receptors to bind the cells (28). This absence of RGD(penton base)-integrin
358 interactions would be the cause of this different intracellular activation after
359 ICOVIR-5 and ICOCAV17 infection. However, both Ads include artificial RGD
360 motifs in the H1 loops of their fibers (15, 16). That positioning of the RGD motif
361 within the knob of Ad fiber protein should make this ligand available for efficient
362 interaction with integrins on the cell membrane (29). Nevertheless, so far is not
363 known whether this RGD(Knob)-integrin interaction would generate the same or
364 different intracellular signaling events comparing with RGD(penton base) motifs.

365 Moreover, other authors have also reported altered responses between
366 human and canine Ads after infection of human cells. Thus, transduction of
367 dendritic cells has shown that the canine adenoviral CAV-2 vectors, in contrast
368 to human adenoviral serotype-5 vectors, provoked minimal upregulation of major
369 histocompatibility complex class I/II and costimulatory molecules (CD40, CD80
370 and CD86), and induced negligible morphological changes indicative of dendritic
371 cell maturation (13). Similarly, transduction of neurons with human and canine
372 adenoviral vectors resulted in distinct transcriptome profiles (14). By the other
373 hand, the CAV-2 capsid is approximately 10-fold-less negatively charged than
374 human Ad5 (28). It is possible that the more neutral net charge of the CAV-2
375 capsid induce a different attachment to MSC, with a different signaling induction
376 after infection. In addition, a more flexible CAV-2-CAR interaction compared to
377 human Ad5-CAR has been suggested (30), which would also have a role in
378 cellular attachment, internalization and intracellular signaling.

379 We propose the hypothesis that the absence of activation of AKT and
380 cJUN pathways by ICOCAV17 may result in a more 'silent' infection that improves

381 the efficacy of dCelyvir. Thus, in ICOVIR-5-infected hMSCs, cellular processes
382 induced by AKT/cJUN phosphorylation may prevent the activation of the same
383 mechanisms induced in dCelyvir. It is tempting to speculate that part of these
384 results may be due to functional differences in viral proteins. Besides, clinical
385 responses in human patients were achieved when hMSCs presented a lower pro-
386 inflammatory profile after Ad infection, indicating some degree of natural Ad-
387 sensitivity between patients (31). Our results open the possibility to develop new
388 oncolytic Ads with these specific properties. In addition, this mechanism of
389 action could be imitated in clinical hCelyvir by selecting specific human allogeneic
390 MSCs on the basis of their limited host response after Ad infection.

500 **Figure Legends**

501 **Fig. 1 NF-KB signaling pathway activity and IRFs phosphorylation after**
502 **adenoviral infection of human and canine MSCs.** All the experiments were
503 performed using hMSCs infected with ICOVIR-5 (MOI 200 PFU/cell) and dMSCs
504 infected with ICOCV17 (MOI 1 PFU/cell). **a** Culture supernatants of infected
505 MSC were collected at various times post-infection and Ad titers measured as
506 described in Methods. Graphs show mean + SD ($n = 3$). Ad titers of hMSCs and
507 dMSCs analyzed at the indicated times post-infection. Graphs show mean+SD
508 ($n = 3$) (\log_{10} scale). **b** Luciferase activity of hMSCs and dMSCs transduced with
509 the NF-KB-reporter lentiviral vector after Ad infection at the indicated times.
510 Graphs show mean + SD fold increase ($n = 3$). **c, d** Western blots of total or
511 nuclear extracts (ne) from hMSCs and dMSCs were probed with the indicated

512 antibodies. Two independent experiments with different MSC donors were
513 performed.

514 **Fig. 2 Array analysis of secreted cytokines in human and canine MSCs after**
515 **Ad infection.** Serum-free medium from hMSCs infected with ICOVIR-5 (MOI 200
516 PFU/cell) and dMSCs infected with ICOCV17 (MOI 1 PFU/cell) for the indicated
517 times was collected and a secretory profile obtained using the Human XL
518 Cytokine Array kit. The heat maps show the detected cytokines above
519 background level in at least one cell type. All 102 cytokines present in the array
520 were identified after 3 h of infection (**a**) whereas only 51 after 24 h (**b**). **c, d**
521 Statistical analysis showing differentially expressed cytokines (infected vs.
522 control ratios) in hMSCs (purple) and dMSCs (yellow) in response to Ad infection
523 (T-test: $p < 0.05$) (**c**, 3 h; **d**, 24 h). Two independent experiments with different
524 MSC donors were performed.

525 **Fig. 3 Signaling pathways regulated by Ad infection in human and canine**
526 **MSCs. a, b** Heat maps showing phospho-kinase profiles in cell lysates of hMSCs
527 and dMSCs infected with ICOVIR-5 (MOI 200 PFU/cell) or ICOCV17 (MOI 1
528 PFU/cell) for the indicated times obtained with the Human Phospho-Kinase
529 Antibody Array. **c, d** Statistical analysis showing differentially expressed
530 phospho-kinases in hMSCs and dMSCs in response to Ad infection at 3 (**c**) or 24
531 h (**d**). (T-test: $p < 0.05$). **e, f** Network presenting cytokines with increased
532 infected/control ratios in hMSCs compared to dMSCs at 3 (**e**) and 24 h (**f**). Line
533 thickness indicates the strength of data support between edges. Colors represent
534 the biological process in which the cytokine is involved according to the legend.

535 **Fig. 4 Differences in replication and signaling between ICOVIR-5 and**
536 **ICOCV17 depending on cell host. a** Scheme showing the experimental design

537 of host-crossed infections. Bright field micrographs (100X total magnification)
538 showing the cytopathic effect observed in HEK293 or DK28CRE cells with cell-
539 free extracts from hMSCs infected with ICOVIR-5 (MOI 200 PFU/cell) (I), dMSCs
540 infected with ICOVIR-5 (MOI 200 PFU/cell) (II), dMSCs infected with ICOCV17
541 (MOI 1 PFU/cell) (III) or hMSCs infected with ICOCV17 (MOI 1 PFU/cell) (IV).
542 In all cases, cell-free extracts were obtained at 72 h post-infection. Uninfected
543 cells were used as controls. **b** Culture supernatants of hMSCs and dMSCs
544 infected with ICOVIR-5 (MOI 200 PFU/cell) or ICOCV17 (MOI 1 PFU/cell) were
545 collected at various times post-infection and Ad titers measured as described in
546 Methods. Graphs show mean + SD ($n = 3$) (\log_{10} scale). **c** Western blots of
547 dMSCs and hMSCs infected for 24 h with ICOVIR-5 (MOI 200 PFU/cell) or
548 ICOCV17 (MOI 1 PFU/cell) were probed with the indicated antibodies. **d**
549 Confocal analysis of dMSCs and hMSCs infected with CAV2-GFP (MOI 10
550 PFU/cell). Positive signal was detected in dMSCs whereas fluorescence was
551 missing in hMSCs.
