31 **Abstract**

32 Considering the current scenario of rising environmental and energy concerns, engineering of Z-
33 scheme photocatalytic systems is in the spotlight. The prime reason for this includes efficient
34 redox abilities and effective space separation along with the migration of photoinduced charge
35 carriers over conventional heterojunction systems. Herein we foreground the stumbling blocks of
36 traditional heterojunction systems and enlighten the generations of Z-scheme photocatalysis
37 originating from liquid-phase to direct Z-scheme photocatalytic systems. We provide substantial
38 criteria and selection aspects of choosing reductive type photocatalysts as a potential aspirant for
39 the Z-scheme photocatalytic system. As Z-scheme photocatalytic systems render effective space
40 separation of photogenerated carriers, active species generation, wide optical absorption and
41 amended redox ability. We focus on comprehensive illustration of all ~~solid-solid~~-state and direct
42 Z-scheme photocatalysts by coupling reductive type photocatalysts with other semiconductor
43 material and explored their potential for efficacious conversion of solar energy into functional
44 energy. Herein, we aim to provide in-depth and updated criteria ~~of-for~~ selecting Z-scheme
45 photocatalysts for CO₂ reduction, water splitting, and nitrogen fixation. Lastly, the article
46 compiles with a conclusive note about future perspectives and challenges accompanying all ~~solid~~
47 solid-state and direct Z-scheme Z photocatalysts and their energy conversion applications.

50 **Keywords:** Reductive photocatalyst; Bio-inspired Z-scheme photocatalysis; Heterojunction
51 formation; Water splitting; CO₂ reduction

1. Introduction

Nowadays, industrial indispensability and accelerating anthropogenic activities have reached ~~to~~ an alarming level. The interminable increasing challenges related to dwindling renewable natural resources, solar energy conservation and environmental pollutions are of great concern [1-3]. The overriding issues impede global energy consumption; therefore, it is indispensable to explore eco-friendly technologies for environment protection and energy resorption. A sought-after advanced oxidation technology (AOT); Honda and Fujishima effect stimulated the age of heterogeneous photocatalysis with titanium dioxide (TiO₂). Photocatalysis involves the photoassisted generation of strong oxidant holes (h⁺) in the valence band (VB) and reductant electrons (e⁻) in the conduction band (CB) of the semiconductor photocatalysts after the absorption of solar energy. In detail, when a semiconductor photocatalyst is exposed under visible-light with energy greater than or equal to their bandgap energy, the VB electrons get promoted to higher-higher-level CB generating a hole behind in VB (Fig. 1a). After excitation, the photoinduced excitons migrate to the surface of photocatalyst. For efficient photocatalysis, the CB electrons should possess strong reduction ability with a chemical potential in the range of +0.5 to -1.5 V (vs NHE) and the VB holes should possess strong oxidising capacity with oxidation potential in the range of +1.0-+3.5 V (vs NHE) [4-11]. The process further involves the interfacial transfer of photocarriers which generates various reactive oxygen species (ROS) like; peroxide (O₂·), superoxide (·O₂⁻), and hydroxyl radicals (·OH) which participate in photodegradation of pollutants, reduction of CO₂ to hydrocarbon fuels, overall water splitting, N₂ fixation and biohazard disinfection [12-15]. However, after excitation, the electrons might reassemble and dissipate the input energy in the form of light or heat which needs to be addressed in order to attain higher photocatalytic efficacy. To date, designing a robust promising photocatalyst to overcome indisputable energy inadequacy and environmental degradation has become a cutting-edge research topic [16-19]. For effectual conversion of solar energy into functional fuels, various reductive type photocatalysts (ZnS, CdS, Ta₃N₅, TaON, Cu₂O, SiC, Bi₂S₃ etc)

1
2
3
4 154 which fulfil the necessary criteria of a photocatalytic process have been reported. However,
5
6 155 the cost-effectiveness and physico-chemical stability hinders their photocatalytic efficiency.
7
8 156 Therefore, to accentuate the journey of delivering large-scale benefits in the province of
9
10 157 photocatalysis, graphitic carbon nitride (g-C₃N₄) has garnered incredible fascination among
11
12 158 scientific communities. Moreover, g-C₃N₄ on account of its hierarchical properties including
13
14 159 appropriate optical band gap ~2.7 eV (with oxidative potential at +1.57 V and reductive at -
15
16 160 1.13 V vs NHE at pH 7) is an utterly smart solar light harvesting photocatalyst [5, 9].
17
18 161 Moreover, its substantially accessible surface sites with high thermal and chemical stability
19
20 162 offers unprecedented breakthroughs in various realms of environment conservation [20, 21].

21 163 For achieving high space charge separation efficacy and broad visible light absorption, many
22
23 164 strategies like, coupling, doping, co-catalyst incorporation and heterojunction construction
24
25 165 have been frequently adopted. Out of all these strategies, heterojunction formation proves its
26
27 166 worth and can be classified as conventional [22-25] and Z-scheme heterojunctions [26-30].
28
29 167 Conventional heterojunction formation involves semiconductor composites which are formed
30
31 168 by the combination of two or more semiconductors depending upon their band gaps [31-37].
32
33 169 These are further of three types as shown in (Fig. 1b-d). In type-I heterojunction, VB of
34
35 170 semiconductor-II (SC-II) lies lower than semiconductor-I (SC-I), and CB of SC-II is higher
36
37 171 than the CB of SC-I forming a straddling gap. The migration of charge carriers proceeds in a
38
39 172 way that gathering of electrons and holes occurs only on SC-I resulting. It causes poor charge
40
41 173 separation of photogenerated electron and hole pairs along with lower redox potential as both
42
43 174 oxidation and reduction reactions occur at the same semiconductor [22, 23]. In type-II
44
45 175 heterojunction, the band positions are at optimal levels (staggered gap) that offer spatial
46
47 176 charge carrier separation with enhanced photocatalytic efficacy as compared to type-I. But its
48
49 177 redox potential is low due to occurrence of oxidation and reduction reactions on SC-I with
50
51 178 lower oxidation potential and SC-II with lower reduction potential. Type-III heterojunctions
52
53 179 have broken gap situation involving separation of charge carriers similar to type-II
54
55 180 heterojunctions [22, 38]. The broken band-gap in type-III heterojunction does not intersect
56
57 181 causing no charge carrier separation for enhanced photocatalytic activity.

3
4 | 183 ~~In order to~~ encounter the aforementioned issues and to achieve superior photocatalytic
5
6 | 184 efficiency, Z-scheme heterojunction systems have intrigued researchers [27, 28]. The
7
8 | 185 concept of Z-scheme photocatalysis was initially introduced by Bard in 1979. Ensuing ideal
9
10 | 186 conditions for photocatalysis, Z-scheme heterojunction results in more negative CB edge
11
12 | 187 and more positive VB edge thus narrowing band-gap of semiconductor [39]. The progression
13
14 | 188 path of Z-scheme photocatalysis from the first generation to the third generation has been
15
16 | 189 depicted in (Fig. 2). In contrast to type-II heterojunction, photogenerated electron-hole pair
17
18 | 190 (EHP) separation in Z-scheme follows a different pathway (Fig. 3b-d). In Z-scheme **mode**,
19
20 | 191 upon visible light irradiation electrons in CB of SC-II combines with photogenerated VB
21
22 | 192 holes of SC-I. This leads to **the** formation of sufficiently strong oxidative VB holes in SC-II
23
24 | 193 and reductive electrons in CB of SC-I. **Due to the difference in band alignment and work**
25
26 | 194 **function of the semiconductor photocatalysts, the resulting induced** interface electric field
27
28 | 195 expedite separation of EHP. The name Z-scheme is proposed because it imitates natural
29
30 | 196 photosynthesis in plants and follows the same mechanism of charge transfer pathway that
31
32 | 197 contains two-step photoexcitation which shows resemblance to the letter 'Z'. Natural
33
34 | 198 photosynthesis involves two photo-induced chemical reactions in PS I (photosystem I) and
35
36 | 199 PS II (photosystem II) with various intermediary enzymes which endorse oxidation and
37
38 | 200 reduction reactions as shown in (Fig. 3a). Firstly, PS I accompanying chlorophyll P680
39
40 | 201 under solar light irradiation are converted to excited state P680* as (Eq.1):

41
42 | 202 Simultaneously, oxidation of water molecules generates O₂ on chlorophyll P680. The
43
44 | 203 electrons migrate from P680* to chlorophyll P700 (accompanying PS II) in presence of
45
46 | 204 enzymatic action via electrons transfer chain. Upon absorption of sun-light, chlorophyll P700
47
48 | 205 changes to excited state chlorophyll P700* as:
49

50 | 207
51
52
53 | 208 The photoexcited electrons react with NADP⁺ to produce reduced coenzyme-II which is
54
55 | 209 further used for the reduction of CO₂ [40]. Z-scheme is categorised into three main
56
57 | 210 generations as depicted in Fig. 3b-d. The first generation is liquid phase Z-scheme
58
59 | 211 photocatalyst, fabricated by coupling of two different semiconductor materials via a shuttle
60
61 | 212 redox liquid-state mediator (species which acts as an electron acceptor and donor (A/D) pair)

[41,42]. Both SC-I and SC-II get photoexcited under solar light illumination and release electrons and holes in CB and VB, respectively (Fig. 3b). Further, migration of CB electrons from SC-II to VB of SC-I takes place through redox mediator by following reactions [Eq. 3 and 4], resulting in the formation of holes in VB of SC-II.

By this process, photoexcited electrons remain on SC-I with more reduction potential, whereas the photogenerated holes remain on SC-II. In this way, the optimal spatial charge separation along with optimized redox potential is achieved. However, there are some typical shortcomings in the first generation of Z-scheme like, (1) Use of reversible shuttle redox mediators like I^{-}/IO_3^{-} and Fe^{2+}/Fe^{3+} causes a backward reaction [22]. During the photochemical reaction, donor and acceptor species like Fe^{2+} and Fe^{3+} will compete with reactants for oxidation and reduction reactions, respectively. So, overall photocatalytic efficacy of Z-scheme system is lowered. Moreover, the liquid phase Z-scheme system is operational in a liquid state only and hence limits its application for gaseous and solid phase systems.

<Please Insert Fig. 2 Here>

The second generation of Z-scheme photocatalysis is all-solid-state (ASS) photocatalytic system [43, 44]. ASS Z-scheme systems are designed by combining two different semiconductor materials and an electron mediator at the surface junction which are usually noble-metal nanoparticles (NPs) (Ag, Au, Pt, Bi and Cu) or carbon materials like (graphene oxide (GO), carbon nanotubes (CNT's), reduced graphene oxide (RGO) and carbon [45] (Fig. 3c). Noble-metal NPs, are proven to be successful in eliminating backward reaction occurring in first-generation Z-scheme systems. However, the applicability of metal NPs (NPs) at semiconductor surface junction is accompanied with certain inherited limitations *i.e.* its high cost, photo-corrosive nature and strong optical light absorption which narrows its wide-scale applications [46]. Thus, mediator free ASS Z-scheme system was introduced by Wang and his peer group in 2009, using ZnO and CdS system in direct contact with each other [47] (Fig. 3d). Thereafter in 2013, the third generation of Z-scheme entitled as direct Z-Scheme

1
2
3
4 243 photocatalyst get acquainted to overcome all drawbacks of first and second-generation Z-
5
6 244 scheme aimed for enhanced photocatalytic efficiency and redox potential. As the name
7
8 245 implies in-direct Z-scheme photocatalyst, two photocatalytic systems form a direct surface
9
10 246 junction with each other omitting requirement of redox mediators or noble metals at interface
11
12 247 thereby, reducing ~~light-light~~-shielding effect and lowering manufacturing cost [48-50].
13
14 248 Though both the Z-scheme system and type-II photocatalytic systems have the same structure
15
16 249 yet their charge separation mechanism is ~~totally~~-different. In direct Z-scheme, photoinduced
17 250 CB electrons in SC-II possessing less reduction potential combine with VB-holes in SC-I with
18
19 251 low oxidation potential. By this means, SC-II is occupied with photogenerated holes
20
21 252 possessing high oxidation potential and photo-irradiated electrons possessing high reduction
22
23 253 potential remains in SC-I thereby, optimum space charge separation along with superior redox
24
25 254 ability is accomplished. Direct Z-scheme photocatalyst attains comparatively greater
26
27 255 photocatalytic activity than the type-II system as the charge migration pathway is
28
29 256 substantially more favourable. In direct Z-scheme, migration of charge carriers is
30
31 257 thermodynamically feasible by electrostatic attraction among photogenerated charge carriers.
32
33 258 For fabrication of direct Z-scheme robust photocatalyst, appropriate band positions with
34
35 259 extended solar light harvesting range ~~is-are~~ required [39, 51-53].

36 <Please Insert Fig. 3 Here>

37 261
38
39 262 Hitherto, intensive research studies have been incorporated on exploring the potential of Z-
40
41 263 scheme photocatalytic systems for environmental and energy concerns [54]. For example, Xu
42
43 264 *et al.* represented a comprehensive viewpoint involving designing, modification and
44
45 265 applications of direct Z-scheme photocatalysts for modulating optoelectronic properties of
46
47 266 semiconductor photocatalysts [55]. Similarly, Low *et al.* summarized potentials of direct Z-
48
49 267 scheme heterojunction systems over conventional double charge transfer system and depicted
50
51 268 the characterization techniques to verify the formation of direct Z-scheme system along with
52
53 269 their useful photocatalytic applications. Considering all the significant efforts to exploit the
54
55 270 fascinating features of Z-scheme photocatalytic systems, the present study summarizes an all-
56
57 271 inclusive overview ~~on-of~~ the criteria and selectivity aspects required for photocatalytic
58
59 272 conversion of CO₂ along with water splitting. We believe that a comprehensive review
60
61 273 focusing on reductive type photocatalyst hybridized with other semiconductor material

1
2
3
4 274 forming ASS and direct Z-scheme system can effectively offer new ideas for selecting and
5
6 275 synthesizing new photocatalysts which can fulfil the criteria of energy conversion
7
8 276 applications. To date, no such study mentioning criteria for photocatalytic CO₂ reduction and
9
10 277 water splitting along with selectivity aspects utilizing reductive type photocatalyst ~~have~~has
11
12 278 been reported. Furthermore, we aim to represent the importance of converting conventional
13
14 279 heterostructure into ASS and direct Z-scheme heterojunction system ~~in order~~ to achieve
15
16 280 amended space charge isolation of photocarriers to carryout photo-redox reactions at distinct
17
18 281 semiconductor materials. We further assume that the critical insight into the mechanistic
19
20 282 viewpoint of ASS and Z-scheme heterostructures could bring substantial improvement in the
21
22 283 field of photocatalysis. To get a measure of the catalog of different research articles related to
23
24 284 ASS and direct Z-scheme photocatalysts, we cruised data with the help of ‘Scopus’ database
25
26 285 as it provides the most significant citations. Moreover, it is one of the most authentic means of
27
28 286 receiving information regarding current drifts and historic progression in the research field.
29
30 287 Through Scopus, we found 2588 and 3181 articles by using keywords “All ~~solid-solid~~-state Z-
31
32 288 scheme photocatalysts” and “Direct Z-scheme photocatalysts, respectively from 2009 to
33
34 289 January, 2020 (Fig. 4a). Furthermore, Fig. 4b and c represent the applicability of ASS and
35
36 290 direct Z-scheme systems in pollutant degradation, CO₂ reduction, overall water splitting and
37
38 291 H₂ production. The main discussion of the present review is divided into the following
39
40 292 sections:

- 41 293 • ~~Basie~~The basic principle of photocatalytic CO₂ reduction and water splitting.
- 42 294 • ~~Selectivity~~The selectivity of the photocatalyst.
- 43 295 • All-solid-state Z-scheme photocatalysts.
- 44 296 • Direct Z-scheme photocatalysts.
- 45 297 • Photocatalytic CO₂ reduction.
- 46 298 • Photocatalytic water splitting.
- 47 299 • Other application.
- 48 300 • Conclusion and viewpoint.

64
65

304 Currently, about 6 billion tons of CO₂ is released into the atmosphere which is causing severe
 305 climate and health issues. As a consequence of elevating-elevated CO₂ levels in the atmosphere,
 306 global warming is one of the growing worldwide concerns. The photoassisted reduction of CO₂
 307 into functional hydrocarbon fuels has become an attractive pursuit to produce clean energy and
 308 tackle the energy and environment problems [56]. The era of photocatalytic CO₂ reduction
 309 started back in the 1970s by the photoconversion of CO₂ into useful organic compounds [57].
 310 Thereafter, with increasing advancements in technology, the process of photocatalytic CO₂
 311 reduction gained significant pace. The photoreduction process mainly involves the recycling of
 312 CO₂ and subsequent generation of functional chemical fuels [58]. In detail, for photo-reduction
 313 of CO₂, the prerequisite condition is the use of appropriate photocatalyst to deploy visible light
 314 and a resulted photoreaction with CO₂ in gaseous or aqueous phase system. As a result of photo-
 315 oxidation reactions, the photocatalyst will reduce CO₂ to different hydrocarbons like methanol,
 316 methane, formic acid hydrogen and formaldehyde which can be utilized as fuel and feedstock for
 317 different reactions depending upon its reduction potential [59]. Since the gaseous CO₂ is
 318 relatively stable with $\Delta G_f^0 = -394.4 \text{ kJmol}^{-1}$, therefore, external energy must be supplied for its
 319 transformation into reduced products [60]. Moreover, for spontaneous photo-reduction of CO₂
 320 ($\Delta G = \text{negative}$), the applied potential should be more negative than the standard reduction
 321 potential. The formal redox potentials required for different photocatalytic CO₂ reduction
 322 reactions can be obtained from thermodynamic studies and are given in [Eq. 5-11](#).

337
338 The efficiency of photocatalytic CO₂ conversion depends directly on the band-gap energy of the
339 photocatalytic material along with appropriate redox potential values. In general, the effective
340 transmission of electrons to the surface of photocatalyst containing adsorbed CO₂ is
341 thermodynamically feasible only if the CB edge of semiconductor material lies at more negative
342 potential than the required standard potential. For instance, the photocatalytic CO₂ reduction into
343 methanol can be facile if the CB of semiconductor photocatalyst lies at potential more negative
344 than -0.38 V which is the standard reduction potential for CO₂ conversion into methanol at pH 7
345 vs. NHE [58, 61].

346 Consequently, a suitable photocatalytic material for photo-reduction of CO₂ must fulfil the
347 following criteria:

- 348 (i) transmission of multiple electrons from photocatalyst to adsorbed CO₂; (ii) the CB
349 positioning in semiconductor photocatalyst should lie at more negative potential than the CO₂
350 redox potential and its subsequent reduced products; (iii) the facile adsorption of reactant
351 molecules like, H₂O, CO₂ and carbonates on photocatalyst and desorption of products through
352 diffusion into the system after photo-reduction reaction; (iv) the photoinduced VB holes of a
353 semiconductor should interact with oxide species (H₂O or other sacrificial agents) to avoid the
354 recombination with electrons as well as secondary reactions with the reduced products (as shown
355 in Eq. 11) [62]. Thus, based on the above discussion it can be assumed that the ability of photo-
356 reduction of CO₂ can be significantly enhanced via the synergistic effect of optimal CO₂
357 adsorption, broad visible light absorption and efficacious charge separation.

358 In general, from the aforementioned chemical equations, it can be seen that there is a need of for
359 hydrogen source and electron donor for the photoassisted reduction of CO₂ which can be fulfilled
360 by H₂O. However, there lies an uncertainty for using H₂O as an electron donor due to its ability
361 to indulge into a side reaction for the production of H₂ as shown by Eq. 10 [63]. During
362 photocatalytic reduction of CO₂, H₂O can undergo both oxidation (by VB holes) and reduction
363 (by CB electrons) to produce O₂ and H₂, respectively. This can significantly obstruct the photo-
364 reduction efficacy of CO₂ into hydrocarbon fuels. Consequently, the overall photoassisted
365 reduction efficiency of CO₂ is comparably lower than that of H₂ generation through water

splitting which is in agreement with thermodynamic and kinetic studies [64]. As per thermodynamic consideration, the photocatalytic CO₂ reduction requires six to eight electrons with more negative reduction value than two-electron reduction process for photocatalytic H₂ generation. Simultaneously, the complex mechanism of CO₂ photo-reduction must involve basic chemical reaction involving the transference of electrons and protons to adsorbed CO₂. Thus, the photocatalyst must overcome thermodynamic as well as the kinetic criterion by generating spatially separated reaction sites to avoid subsequent H₂ production and facile photocarriers transfer- to CO₂ [62,64,65]. So far, Z-scheme photocatalysts are capable to exhibit effective space separation of photocarriers and incremented redox abilities for efficient photo-reduction of CO₂ into hydrocarbons. **The effectual migration and space isolation via Z-scheme mode renders superior redox ability to the photocatalytic system which can be substantially utilised in photoreduction reaction.**

3. Basic-The basic principle of photocatalytic water splitting

The increasing concerns of environment and energy disputes have led researchers to exploit sustainable and re-generated fuels possessing energy-dense and green features [66-69]. Hydrogen (H₂), a carbon-carbon-free energy carrier owning exceptional energy density along with heat value 120-140 MJkg⁻¹, is a best-best-suited alternative till date to replace traditional fossil fuels as it does not generate pollutants during combustion. Currently, about 44.5 million tons of H₂ is produced worldwide and with such production rate, it will take years for H₂ to become the primary source of energy [70]. Artificial photosynthesis phenomenon for photocatalytic solar to chemical energy conversion offers highly significant means to generate fuels from the water with minimal impact on the environment. Utilizing solar energy and joining it with water by-means-ofutilizing photoassisted water splitting offers a great deal for H₂ generation. In photocatalytic water splitting, water is introduced into a module designed for water splitting and converted into H₂, which is further utilized in systems to generate high-high-efficiency power. Considering that, the basic criteria of generating H₂ and O₂ at the solid-liquid interface strictly rely on efficient visible light harvesting. As such, the efficacious utilization of visible light leads to the conversion of solar energy into chemical functional energy and its storage for further usage [71, 72]. Overall water splitting into H₂ and O₂ is an uphill chemical reaction (Eq. 16) which accompanies an increase in Gibbs free energy [73] as shown below:

Due to uphill reaction kinetics, there is a need ~~of-for~~ external energy to carry out the ~~water-water-~~ splitting reaction. In photocatalytic water splitting, visible light is the external driving force which converts solar energy into hydrogen by utilizing water as ~~the~~ only reactant. Due to slow reaction kinetics, the involvement of semiconductor photocatalysts into the phenomenon becomes necessary. The basic criteria to evolve H₂ and O₂ involve the absorption of photons by semiconductor photocatalyst to generate holes and electrons which participate in the oxidation of H₂O and reduction of H⁺, respectively. Moreover, the overall aspects including efficacy, cost-effectiveness and stability must be superior in comparison with industrial processes of generating H₂ ~~in-order~~ to achieve the widespread application of visibly driven photocatalytic water splitting. In detail, during photocatalytic water splitting following steps take place; (i) After absorbing energy greater than ~~the~~ band-gap of ~~the~~ semiconductor, VB electrons get excited to CB thereby, **produce** electrons and holes (ii) photo-excited electrons and holes independently get diffused on ~~the~~ semiconductor surface, **and** (iii) subsequently undergoes surface chemical reactions involving oxidation and reduction of water by photogenerated holes and electrons to produce O₂ and H₂, respectively as shown **by** (Eq. 17 and 18);

Thermodynamically, the prerequisites for aforementioned reactions to proceed are; the CB minimum for a photocatalyst must lie at more negative potential than that of H⁺/H₂ level (0 **V** vs. NHE at 0.059 pH), while the VB maximum should be more positive than that of O₂/H₂O energy level (1.23 **V** Vs. NHE) [74]. Precisely, ~~in-order~~ to achieve photocatalytic OWS, a photocatalyst must overcome an energy barrier of 1.23 eV. Moreover, oxidation/reduction of water by photogenerated holes/electrons greatly depends upon band positioning of photocatalysts and redox potential of water which should be precisely matched. The schematic illustration for water splitting process is shown in (Fig. 5). In general, water splitting is a complex phenomenon posing

1
2
3
4 427 stringent conditions of selecting a photocatalyst with suitable band positioning for H₂ and O₂
5
6 428 evolution. Despite ~~of~~ considerable exploitation and development in the field of photocatalysis,
7
8 429 the efficiency and stability of photocatalytic water splitting still faces huge challenges from both
9
10 430 thermodynamic as well as kinetic factors due to the unsatisfactory catalytic features of the
11
12 431 semiconductor material. Moreover, notably, the insufficient STH **conversion** efficiency is
13
14 432 another factor that needs to be addressed effectively. For this purpose, sacrificial reagents like
15
16 433 methanol (CH₃OH) and sodium thiosulphate (Na₂S₂O₈) are used as irreversible electron donor
17
18 434 and acceptor in hydrogen evolution reaction (HER) and oxygen evolution reaction (OER),
19
20 435 respectively. In contrast, sacrificial half-reactions are downhill reactions comprising decrease in
21
22 436 Gibbs free energy, also photon energy doesn't get stored, hence, it is important to design
23
24 437 photocatalysts which do not need these reagents [75]. Till date, many photocatalytic water
25
26 438 splitting systems involving sacrificial agents have been reported where they promote the
27
28 439 suppression of EHP by depleting holes or by providing hydrogen atoms for H₂ evolution.
29
30 440 Besides, adding sacrificial agents into the photocatalysis generates extra chemical energy into the
31
32 441 reaction except for solar energy. Moreover, the sluggish reaction kinetics inhibits the overall
33
34 442 efficiency of photocatalytic water splitting. Thus exploring semiconductor photocatalysts with
35
36 443 significantly high-efficacy, stability, economical and physicochemical features is of utmost
37
38 444 concern for the growth of photocatalytic water splitting.

39 445
40
41 446 **<Please Insert Fig. 5 Here>**

42 447 **4. Selectivity of photocatalyst**

43 448 Typically, the selection of photocatalyst and various strategies to improve photocatalytic
44
45 449 performance **are the** most crucial aspects to be considered for achieving superior efficacy.
46
47 450 Besides, to attain ~~pilot-pilot~~-scale applications of the photocatalyst; recyclability, reusability and
48
49 451 photo-stability of the photocatalytic material **are** equally **substantial**. Visibly driven
50
51 452 photocatalytic water splitting process ~~as well as photoreduction of CO₂, as well as~~
52
53 453 photoreduction of CO₂, can be classified into three main steps: absorption of a photon,
54
55 454 migration/separation of photocarriers, and surface redox reactions. These steps strictly depend
56
57 455 upon the type of photocatalyst being employed in the photocatalytic process as discussed below.
58
59 456 The effectiveness of any photocatalytic process **firmly** relies on the band-gap energy as well as
60
61 457 band edge positioning of semiconductor material for efficient absorption of a photon. Since, the

1
2
3
4 458 initial step of photocatalysis involves the effectual harnessing of visible light which in a way
5
6 459 depends upon the bandgap energy of the semiconductor photocatalyst. In detail, upon visible
7
8 460 light exposure, the semiconductor photocatalyst possessing appropriate bandgap energy (E_g) can
9
10 461 produce photoinduced EHP by the excitation of electrons from VB of a photocatalyst to its CB
11
12 462 leaving holes behind. Only after this important step, the photocatalytic process can further
13
14 463 proceed. However, the obstacle of photocarriers recombination can significantly limit the
15
16 464 effective number of photocarriers reaching at the surface of photocatalyst which can hinder the
17
18 465 overall efficacy of the photocatalytic process. Furthermore, for adequate enhancement in the
19
20 466 photon absorption process, band engineering plays a vital role. For instance, band-gap tuning of
21
22 467 the photocatalyst through doping is one of the most crucial techniques used for this purpose [76].
23
24 468 It is widely investigated that the addition of metallic and non-metallic impurities in
25
26 469 heterojunction system can effectively enhance photoactivity by lowering the band-gap energy,
27
28 470 boosting the visible light harnessing and imparting useful physical features [77]. To date, various
29
30 471 metallic and non-metallic dopants such as; Sodium (Na), lithium (Li), copper (Cu), iron (Fe),
31
32 472 carbon (c), phosphorous (P), boron (B), sulphur (S), oxygen (O), and so many others have been
33
34 473 extensively explored [78-80]. The introduction of metal dopants into the photocatalytic system
35
36 474 can adequately enhance the solar light harvesting, decrease the band-gap and boost the
37
38 475 photocatalytic performance by improving the movement rate of photocarriers as well as by
39
40 476 reducing the reassembly of EHP [81]. For example, Gao *et al.* reported a one-step pyrolysis
41
42 477 process to design Fe-doped g-C₃N₄ nanosheets (NSs) which exhibited significantly enhanced
43
44 478 MB degradation efficacy as well as H₂ production rate [82]. Doping of g-C₃N₄ with Fe
45
46 479 remarkably increments the photocatalytic performance of g-C₃N₄ by tuning its electronic
47
48 480 properties. It is observed that, non-metal dopants are preferred over metal dopants as by doping
49
50 481 the system with a metal ion, the thermal stability of the system significantly decreases due to
51
52 482 mid-gap energy levels [83]. While due to high electronegativity and high ionization energy, the
53
54 483 non-metal dopants control the thermal changes and maintain the metal-free behaviour of the
55
56 484 system. Thus, through band-gap engineering, photocatalytic efficacy of the system can be
57
58 485 significantly improved by means of employing effective thermal and electronic features which
59
60 486 can boost the harnessing of visible light.

So far, it is observed that the photocatalysts with wide band-gap energy cannot harvest solar energy efficiently and the photocatalysts with narrow band-gap energy undergo quick reassembly

1
2
3
4 489 of photocarriers. As a consequence, the overall photocatalytic efficacy of the system drops
5
6 490 substantially. The second step that involves effective migration and separation of photoinduced
7
8 491 carriers play a crucial role to increment the photoactivity of the system. For instance, crystallinity
9
10 492 and surface morphology of the photocatalyst strongly affects the photocatalytic efficiency of the
11
12 493 system [84, 85]. Since, EHP generation ~~as well as separation, as well as separation,~~ depends on
13
14 494 both crystallinity and surface properties of the photocatalyst. Generally, highly crystalline
15
16 495 semiconductor materials render significantly high photocatalytic activity. Moreover, highly
17
18 496 crystalline photocatalyst owing to minimal surface defects can effectively inhibit EHP
19
20 497 recombination sites. The reduced particle size of the photocatalyst can also increment the
21
22 498 photoactivity due to diminished EHP diffusion length [86-88]. Furthermore, trapping of
23
24 499 photocarriers in a shallow energy range resides s near the band edge level can be utilized to
25
26 500 enhance the lifespan of EHP as well as to enhance their spatial separation [89]. Alongside,
27
28 501 trapping of photocarriers significantly decreases their mobility as well as energetics [90]. For
29
30 502 example, a sample of g-C₃N₄ holds a superior concentration of trapped electrons with the high
31
32 503 lifespan of a microsecond to second [91]. However, due to profound trapping, these electrons
33
34 504 could barely migrate to the surface sites of photocatalyst and participate in the photocatalytic
35
36 505 process. Thus, some other strategies for superior migration and separation of photocarriers
37
38 506 involve shortening of transmission distance, reduced surface defects and formation of
39
40 507 heterojunction systems. In order to shorten the transmission distance for efficient charge
41
42 508 migration and separation, reduction in particle size of photocatalytic material can be very useful
43
44 509 [90]. Since, the possibility of EHP reassembly is very high with the suspended NPs with lesser
45
46 510 size than that of electron-hole diffusion lengths. Through optimal starting material and synthesis
47
48 511 routes, the particle size of the photocatalysts can be controlled. As the NPs with appropriately
49
50 512 smaller size provides short diffusion distance through which carriers can easily transfer to the
51
52 513 active surface sites and play a part in the process. Although defects at surface morphology act as
53
54 514 active reaction sites and reduce the reassembly rate of EHP. However, the presence of killer
55
56 515 defects at the surface of photocatalytic material serves as a recombination centre which greatly
57
58 516 affects the photoactivity [92]. For controlling the surface defects and to promote the crystallinity
59
60 517 of g-C₃N₄, a molten salt flux strategy by utilizing the mixture of NaCl/KCl was reported [93].
61
62 518 The addition of a mixture of salts in the synthesis remarkably enhanced the crystallinity and
63
64 519 inhibits the formation of defects. Such a technique can be utilized to synthesise different
65

1
2
3
4 520 photocatalysts (SrTiO₃, Sn₂TiO₄, Ta₃N₅ etc.) with high crystallinity and ~~less~~-fewer defects
5
6 521 [90,94,95]. Another frequently functionalized technique to suppress the reassembly of
7
8 522 photocarriers is the tailoring of heterojunction systems. Till date, the formation of Z-scheme
9
10 523 systems utilizing two or more than two semiconductor photocatalysts is greatly explored. The
11
12 524 superior mechanistic functioning of Z-scheme system facilitates the effective separation and
13
14 525 migration of photocarriers by inhibiting the reassembly of charge carriers. The systematic
15
16 526 representation of different selectivity aspects along with the criteria to achieve them is
17 527 represented in Fig. 6.
18

19
20 528 **<Please Insert Fig. 6 Here>**
21

22 529 Although, scientists have paid due attention to develop new advanced semiconductor
23
24 530 photocatalysts to harvest solar light for various photocatalytic applications. **However widespread**
25
26 531 **applicability of photocatalytic material could be achieved if it is** cost-effective and derived from
27
28 532 ~~earth-earth~~-abundant precursors. Compounds of Re, Ru, Os, Rh, Ir, Pd, Pt, Ag and Au are not
29
30 533 referred as ~~earth-earth~~-abundant as they are very costly due to the use of expensive precursors
31
32 534 which limits their applicability on a commercial scale. However, the transition ~~metal-metal~~-based
33
34 535 photocatalysts involving the compounds of Mn, Fe, Co, Ni, Mo, Cu, and W are widely explored
35
36 536 due to their ~~earth-earth~~-abundant feedstock and significant photocatalytic features. Oxides of Fe
37
38 537 for various photocatalytic applications have been heavily exploited as they are appealing
39
40 538 photocatalytic material and globally scalable [96]. Besides, abundance and cost-efficiency of
41
42 539 iron makes it a more suitable photocatalyst for the clean energy conversion process. Other than
43
44 540 transition metals, carbonaceous materials namely graphene, and g-C₃N₄ are metal-free
45
46 541 semiconductor material obtained from ~~earth-earth~~-abundant C and N rich precursors. Moreover,
47
48 542 exceptionally high physicochemical stability and **non-toxicity of g-C₃N₄ makes it more**
49
50 543 **favourable and broadly utilized** photocatalyst.

51
52 544 Other parameters which influence the selection of photocatalytic material involve the separation
53
54 545 and recycling ability of the photocatalyst. To maintain the cost-effectiveness in photocatalysis it
55
56 546 is equally essential that a photocatalytic material can be easily separated from the **reaction**
57
58 547 **mixture** and recovered for further usage. It is a well-known fact that photocatalyst with particle
59
60 548 size less than 1 μm offers great activity and stability as it experiences significantly low attrition.
61
62 549 But the main difficulty of utilising such small particles is their separation from the reaction
63
64
65

1
2
3
4 550 mixture. Selecting a photocatalytic material with magnetically rich properties can be a useful
5
6 551 approach for the efficient separation of photocatalysts [97]. Thus, a significant advancement in
7
8 552 this area can be explored to develop more photocatalysts with high magnetic behaviour for ease
9
10 553 of separation. Other than this, immobilizing the nano-size powdered photocatalyst with a
11
12 554 supporting material can effectively improve the separation without consuming much time. Since
13
14 555 without immobilization, **the chances of inefficient separation along with significant loss of**
15 556 **photocatalyst are very high** [98]. For instance, powdery g-C₃N₄ nanocatalysts do not exhibit
16
17 557 magnetisation and are difficult to separate from the system. Consequently, it becomes important
18
19 558 to develop a facile technique for the efficient immobilization of g-C₃N₄ utilizing a proper
20
21 559 supporting material which avoids the costly as well as ~~time-time~~-consuming separation process.
22
23 560 For instance, Dong *et al.* immobilized powdery g-C₃N₄ nanocatalyst on well-arranged Al₂O₃
24
25 561 ceramic foam through the in-situ process [98]. It was observed that the optimal immobilization
26
27 562 of g-C₃N₄ on Al₂O₃ supports was effectively achieved by pyrolysis at 600 °C for about 2 h.
28
29 563 Moreover, the immobilized g-C₃N₄ photocatalyst exhibited excellent stability and recycling
30 564 efficiency without deactivation.

31
32 565 The difficulties arise from the applicability of photocatalyst from laboratory to pilot scale
33
34 566 applications which demand low-low-cost photocatalysts which exhibit superior redox ability and
35
36 567 quantum efficiency. A more reliable mechanistic approach regarding solar light harvesting,
37
38 568 separation of photocarriers, surface redox reactions, photocatalyst-liquid interface interaction and
39
40 569 photo-reactor design should be incorporated for the widespread practical applications of the
41
42 570 photocatalyst. Noteworthy, the biggest task of comparing various photocatalytic materials
43
44 571 originates from the different reaction conditions along with variation in photocatalytic activity
45
46 572 measurement [78]. Ultimately selecting an optimal photocatalyst which exhibits superior
47
48 573 photocatalytic properties including, effectual visible light harnessing, separation/migration of
49
50 574 charge carriers, effective transmission of photocarriers to the surface and significant surface
51 575 adsorption capacity fulfils the basic condition in order to attain higher quantum efficiency.

52
53 576 Till date, various photocatalytic materials with significant photocatalytic activities have been
54
55 577 reported for various **photoassisted** activities [99-105]. Various reduction type photocatalysts like;
56
57 578 CdS, TaON, Cu₂O, Ta₃N₅, SiC, ZnS, Bi₂S₃ etc. have been successfully utilized for photo-
58
59 579 reduction of CO₂ as well as for H₂ generation (Fig. 7). Out of all these photocatalysts, **graphite**

1
2
3
4 | 580 graphite-like g-C₃N₄ is a most fascinating metal-free conjugated photocatalytic material due to
5
6 | 581 its amazing physical as well as chemical features. The past few years have observed a g-C₃N₄-
7
8 | 582 driven “gold-rush” excelling in the field of photocatalysis as an outstanding 2D metal-free
9
10 | 583 conjugated polymer. Its low-cost, ~~earth-earth~~-abundant and facile synthesis involving nitrogen
11
12 | 584 nitrogen-rich precursors like urea [106,107], melamine [108-110], thiourea [111,112] and
13
14 | 585 dicyandiamide [113,114] ~~has~~-have spurred enormous interests of research groups. In case of g-
15
16 | 586 C₃N₄, its CB potential locates around -1.12 V vs. NHE (pH = 0) and its VB potential locates at
17
18 | 587 about 1.57 V. It is noteworthy that an oxidation photocatalyst with low VB edge position
19
20 | 588 exhibits strong oxidation potential while, a reduction photocatalyst generally with high CB edge
21
22 | 589 shows strong reduction ability [115]. Therefore, from the CB position of g-C₃N₄ (-1.12 V), it is
23
24 | 590 evident that it is a reduction type photocatalyst with high reduction potential which is highly
25
26 | 591 suitable for CO₂ reduction and water splitting through Z-scheme pathway. Since, Z-scheme
27
28 | 592 charge transfer mode renders exceptionally high space charge separation efficiency and
29
30 | 593 maintains considerably high redox ability of the system which is highly desired in
31
32 | 594 photoconversion applications.

32 | 595 <Please Insert Fig. 7 Here>
33
34 | 596
35

36 | 597 **5. All-Solid-State Z-scheme photocatalysts**

37
38 | 598 In 2006, the ~~first-first~~-ever all-solid-state Z-scheme TiO₂-Au-Cds system was constructed via a
39
40 | 599 photochemical deposition-precipitation route which involved photoreduction of Au NPs (NPs)
41
42 | 600 on TiO₂ surface. The photo-reduced Au NPs act as reduction sites with CdS shell around and
43
44 | 601 accelerated photocarrier’s separation in ASS TiO₂-Au-CdS Z-scheme. The idea of solid electron
45
46 | 602 mediator gained due attention of researchers because of the improved photocatalytic ability of an
47
48 | 603 as-obtained ternary system (TiO₂-Au-CdS) than binary systems (Au-TiO₂ and TiO₂-CdS) [116].
49
50 | 604 An ASS Z-scheme photocatalytic system is fabricated without A/D pair, instead, a solid electron
51
52 | 605 mediator (M) is used at the surface junction of two semiconductors which can be mentioned as
53
54 | 606 SC-M-SC. By inserting a conductor (electron mediator), ~~an~~-ohmic contact with small resistance
55
56 | 607 is generated at the interface [117,118]. Because of this ohmic contact, the photo-irradiated CB
57
58 | 608 electrons from SC-II can recombine directly with photoinduced holes from the VB of SC-I which
59
60 | 609 lowers the distance of electron migration pathway in Z-scheme. Moreover, the absence of redox
61
62 | 610 mediator perfectly avoids backward reactions occurring in the first-first-generation Z-scheme

1
2
3
4 611 system. Also, overall redox potential ability is increased as photoinduced electrons and holes in
5
6 612 CB of SC-I and in VB of SC-II, respectively, are mostly reserved for forwarding redox reactions.
7
8 613 Additionally, the absence of liquid-phase A/D pair in SC-M-SC systems extends its applications
9
10 614 in both gaseous and ~~solid-solid~~-phase conditions for water splitting and photoreduction of CO₂
11
12 615 (Table 1). Electron mediators are comprised of redox mediators, conductors involving noble
13
14 616 metal NPs and carbon materials which are applicable in liquid-phase Z-scheme (1st generation Z-
15
16 617 scheme). However, redox mediators **limit the wide-wide-scale** application of Z-scheme system
17
18 618 because of backward reactions, less ~~light-light~~-harvesting and significantly poor tolerance
19
20 619 towards pH change in photocatalytic **reactions** [119, 120]. In ASS Z-scheme systems, metal NPs
21
22 620 like Au, Ag, Pt, Cu and Bi, and carbon family members; (GO, CNT, rGO, fullerene and carbon
23
24 621 nanosheets (CNS)) are employed as solid electron mediators owing to rapid photocarriers
25
26 622 separation **as they act as electron sink** [121-123]. Mediators and solid conductors act as a charge
27
28 623 diffusion bridge in ASS Z-scheme system which endows **significant isolation of photoinduced**
29
30 624 **excitons. The following section will summarise ASS Z-scheme systems with different electron**
31
32 625 **mediators (noble metal NPs and carbonaceous material) in photocatalysis.**

32 626 5.1 Noble ~~metal-metal~~-mediated ASS photocatalysts

33
34 627 **Inherent anticorrosive nature of noble metals with** resistance to chemical action and oxidation at
35
36 628 high temperature expand **their utilization** in photocatalytic applications. The prominent feature of
37
38 629 noble metal NPs ~~is-in~~ **the** presence of absorption bands in optical spectral range due to resonance
39
40 630 plasmon excitation. The existence of this plasmonic resonance is complemented by a sharp
41
42 631 increase of electric field amplitude inside and around NPs leading to plasmon-excitons. It is
43
44 632 widely apprehended that noble metal NPs can function as traps and **boosted the transfer** efficacy
45
46 633 of **photocarriers** [124]. Besides, noble metal NPs exhibit surface plasmon resonance (SPR) that
47
48 634 reinforce optical absorption of bulk g-C₃N₄ and at **the** same time foster thermal redox ability
49
50 635 during photocatalytic reactions [125]. Recently, a sandwich-structured ternary photocatalyst
51
52 636 CdS/Au/g-C₃N₄ with sulphur-doping was designed by bath deposition method [126]. The
53
54 637 incremented photocatalytic activity of resulted ternary system was governed by water splitting
55
56 638 and dye degradation applications as compared to binary systems CdS/g-C₃N₄ and Au/g-C₃N₄.
57
58 639 The experimental results were explained using the Z-scheme charge migration mechanism in
59
60 640 which Au NPs acted as electron transfer mediator. ~~In-order-t~~o fabricate a tunable heterojunction
61
62 641 photocatalyst CdS/Au/g-C₃N₄, Au@CdS ~~core-core~~-shell assembly was placed onto the g-C₃N₄

1
2
3
4 642 surface. The photocatalytic activity of heterojunction photocatalyst incremented about 125.8
5
6 643 times for hydrogen production compared to bulk g-C₃N₄ **under** visible light **irradiation**. These
7
8 644 reports signify that a ternary photocatalyst involving both noble metal NPs and semiconductor is
9
10 645 an effectual strategy for enhancing photocatalytic efficacy of g-C₃N₄. Moreover, synthesis
11
12 646 procedure used to tailor ternary photocatalytic system CdS-Au-g-C₃N₄ turned out to be a major
13
14 647 drawback since binary composite CdS-g-C₃N₄ is still found in resulting ternary composite. To
15 | 648 surmount the aforementioned drawbacks, a more facile synthetic technique is ~~practiced~~practised
16
17 649 comprising of two-step photoreduction method.

18
19 650 In another work, Gao *et al.* utilized Ag metal NPs as an electron mediator and designed g-
20
21 651 C₃N₄/Ag/LaFeO₃ nanocomposite through photoreduction deposition followed by hydrothermal
22
23 652 route [127]. It was observed that the three-component ASS Z-scheme photocatalytic system
24
25 653 exhibited exceedingly well photoactivity than those of single as well two-component system due
26 | 654 to the SPR effect of Ag metal. The SPR effect induced by Ag metal NPs established an internal
27
28 655 electric field in the Z-scheme system which helped in the effectual separation of photocarriers.
29
30 656 The presence of Ag **metal** NPs in the microstructure of g-C₃N₄/Ag/LaFeO₃ nanocomposite was
31
32 657 analysed by HR-TEM examination (Fig. 8a and b). The intact contact between g-C₃N₄ and
33 | 658 LaFeO₃ was ~~clearly~~ visible along with deposited Ag NPs at the surface junction utilizing the
34
35 659 scale of about 10 nm. Other than HR-TEM, XPS spectra were also observed to investigate the
36
37 660 presence of Ag NPs in the Z-scheme heterojunction system. The XPS spectral studies indicated
38
39 661 the presence of all the respective elements present in g-C₃N₄/Ag/LaFeO₃ ASS system along with
40
41 | 662 their orbitals. Moreover, the Ag 3d spectra displayed the presence of both photo~~s~~s reduced Ag⁺
42
43 663 (with corresponding peaks at 368.2 eV and 374.2 eV) and Ag (with corresponding peaks at 367.6
44 | 664 eV and 373.5 eV). **The effectiveness of charge migration and isolation was scrutinized via EIS**
45
46 665 **(Fig. 8c) and photoinduced fluorescence spectroscopy (Fig. 8d) which demonstrated significantly**
47
48 666 **deprived recombination rate of photocarriers in ternary g-C₃N₄/Ag/LaFeO₃ ASS system as**
49
50 667 **compared with pristine and binary heterostructures.** Consequently, the ASS Z-scheme
51
52 668 heterojunction systems having noble-metal NPs as electron mediator remarkably boost the
53
54 669 photocatalytic efficiency by effectively broadening the visible light response range along with
55
56 670 increment in photocarriers migration and separation.

57 671 **<Please Insert Fig. 8 Here>**
58
59
60
61
62
63
64
65

1
2
3
4 672 Pt as noble metal NPs ~~have~~has been vastly utilised as one of the most effectual cocatalysts in
5
6 673 ~~water-water~~-splitting reactions owing to its unique features which can modulate the selectivity
7
8 674 and activity of a photoreaction depending upon its size [102]. Besides, the electron sink
9
10 675 (acceptor/donor) ability of Pt NPs also facilitates its utilisation as electron transmission mediator
11
12 676 in Z-scheme photocatalysis. For instance, Wang *et al.* reported Pt noble metal NPs as electron
13
14 677 transmission bridge between PCN and TiO₂@C fabricated through impregnation followed by
15
16 678 calcination (Fig. 9a) which facilitated electron migration from macroporous ~~carbon-carbon-~~
17
18 679 coated TiO₂ (TiO₂@C)→Pt→g-C₃N₄ [128]. Formation of ASS Z-scheme photocatalyst rendered
19
20 680 effectual space charge separation which boosted photocatalytic CO₂ reduction into CH₄ with a
21
22 681 rate of 6.56 μmolh⁻¹ and quantum efficacy 5.67%. Improved charge carrier separation kinetics
23
24 682 favoured by ASS heterostructure system was confirmed by intense transient photocurrent
25
26 683 responses and decreased Photoluminescence (PL) peak intensity of as-synthesised DOM-CNPTC
27
28 684 nanocomposite. Fig. 9b depicts photocurrent responses of various samples which suggested
29
30 685 superior charge migration kinetics in 3DOM-CNPTC nanocomposite with highest photocurrent
31
32 686 responses. In another work, charge carrier kinetics of a narrow band semiconductor material
33
34 687 Cu₂ZnSnS₄ (CZTC) was improved by forming its Z-scheme heterostructure with g-C₃N₄ through
35
36 688 Pt as electron migration bridge [129]. Through LSV curves (Fig. 9c), the slight increase in
37
38 689 current density under light illumination was observed which signified extended absorption in
39
40 690 visible light leading to amended electronic features due to the involvement of Pt and CZTS.
41
42 691 Surface plasmonic resonance along with electron sink property of Pt synergistically boosted
43
44 692 opto-electronic features of as-resulted CZTS@Pt/g-C₃N₄ nanocomposite. The photocatalytic
45
46 693 ability of CZTS@Pt/g-C₃N₄ ASS Z-scheme system was evaluated for photocatalytic CO₂
47
48 694 conversion into CO and CH₄ with average yields of 17.351 and 7.961 μmolg⁻¹h⁻¹ which was
49
50 695 about 3.31 and 5.56 times higher than bare g-C₃N₄. The mechanistic insight representing
51
52 696 potentials and pathway of effectual photocatalytic CO₂ reduction *via* more feasible Z-scheme
53
54 697 mode over conventional type-I mode is depicted in Fig. 9d.
55
56 698 Summarily, combining two semiconductor photocatalysts with a noble metal NP as electron
57
58 699 mediator serves as a great for amended visible light harnessing and space charge isolation of
60
61 700 photoinduced excitons. As a result, the photoreaction kinetics of photocatalytic system gets
62
63 701 significantly improved owing to the presence of abundant charge carriers at the surface of
64
65 702 photocatalyst which can participate in photo-redox reactions. However, ~~in spite of~~despite such

fascinating features, certain inherent drawbacks of noble metal NPs limit the wide-wide-scale applicability of them in photocatalysis.

<Please Insert Fig. 9 Here>

5.2 Carbon mediated ASS photocatalysts

Low-Low-cost carbon materials also serve as electron mediators in ASS Z-scheme photocatalysts since noble metals are expensive, photo-corrosive, and their recovery from solution is time-consuming. Carbon-Carbon-based materials have more active surface sites and can act as good sink and transporters of electrons [130]. Besides, the photostability of these materials under varying reaction conditions imparts exceptionally high reusability which boosts their performance as a catalyst for various solar energy conversion applications. For instance, in a fascinating work, Hu *et al.* represented the dual role of RGO as electron transmission bridge and binder in g-C₃N₄/BiOI/RGO ASS Z-scheme heterojunction system immobilized on Ni foam for efficient photocatalytic CO₂ reduction [131]. The enhancement in photoefficiency of the Z-scheme system was ascribed by effectual isolation and space separation of charge carriers owing to the incorporation of RGO as electron mediator and substantial difference in work functions of g-C₃N₄, BiOI and RGO which facilitated the migration of electrons from CB of g-C₃N₄ to VB of BiOI via RGO. The unique and significant role of carbonaceous material as electron sink and transfer medium not only foster electron migration but also improve the availability of excitons of photo-induced surface reactions leading to excellent photoactivity. 0D carbon dots (CD) are also facilely utilised as an electron mediator in a Z-scheme assembly of NiFe₂O₄ (NFO)/g-C₃N₄ (CN) fabricated through a simple wet chemical method [132]. Incorporation of 0D CD aided to convert a type-II heterojunction into Z-scheme system with CD as electron donor/acceptor moiety. The improved charge carrier separation efficacy of ASS Z-scheme NFO/CN/CD nanoheterostructure was analysed with PL spectroscopic analysis which showed significantly decreased PL intensity of the nanocomposite as compared to bare samples.

In a similar study, nanocarbon (C) as solid electron mediator in ASS g-C₃N₄/ZnIn₂S₄ (ZIS) Z-scheme photocatalytic system was reported [133]. The photoactivity of the as-tailored system was assessed by H₂ production through water splitting. Moreover, the synergic effect of g-C₃N₄ coupled with nanocarbon coated ZIS boosted the photocatalytic H₂ generation due to the unique visible light harnessing as well as conducting ability of graphic phase nanocarbon. Due to the

1
2
3
4 734 conducting behaviour of nanocarbon present at the interface of g-C₃N₄ and ZIS, the transference
5
6 735 of electrons and holes was significantly improved. SEM and TEM analysis ~~were~~ was utilized to
7
8 736 examine the microstructure and composition of the as-synthesised g-C₃N₄/C/ZIS system as
9
10 737 depicted in Fig. 10a-c. From HR-TEM analysis (Fig. 10c) the lattice spacing of 0.328 nm and
11
12 738 0.321 nm corresponded to (002) plane of g-C₃N₄ and (102) plane of hexagonal ZIS, respectively
13
14 739 were observed. While the ~~solid-solid~~-state nanocarbon electron mediator having deprived
15
16 740 crystallinity did not show any clear lattice fringes. To further explore the presence of nanocarbon
17
18 741 in the tailored g-C₃N₄/C/ZIS nanocomposite, thermogravimetric (TG) analysis were performed
19
20 742 as shown in Fig. 10d and e. With increasing temperature range (400-602 °C) gradual decrease in
21
22 743 the weight of g-C₃N₄/C/ZIS ASS Z-scheme system was observed suggesting the ignition of
23
24 744 nanocarbon at this temperature. Furthermore, Raman spectrum displayed two apparent peaks at
25
26 745 1375 and 1523 cm⁻¹ which were ascribed to disordered (D) band and graphitic (G) band of
27
28 746 carbon, respectively, and confirmed the presence of graphic carbon in the nanocomposite Fig.
29
30 747 10f.

31
32 749 <Please Insert Fig. 10 Here>

33
34 750 Thus, **solid-state** electron mediator in the **ASS Z-scheme** systems can efficiently promote the
35
36 751 migration of photocarriers and boost the photocatalytic performance **by causing spatially**
37
38 752 **separated charge carriers to induce photo-redox reactions at different semiconductors.** However,
39
40 753 using solid-state electron mediator as a transmission bridge between two semiconductor
41
42 754 photocatalysts accompany several adverse effects on the overall photocatalytic efficacy which
43
44 755 are summarized as below;

- 44
45 756 (i) Use of coloured material in the electron transference process affects the effectual
46
47 757 harnessing of visible light.
- 48
49 758 (ii) Costly noble metal NPs are not only rare but also obstruct the visible light absorption
50
51 759 due to their tendency to act as a strong absorber.
- 52
53 760 (iii) The presence of photocorrosive noble metals substantially limits the photocatalytic
54
55 761 activity over varying pH range.
- 56
57 762 (iv) The transmission distance of electrons from one semiconductor to another is
58
59 763 significantly large due to the presence of solid electron mediator.

59
60
61
62
63
64
65

764 Therefore, it became necessary to tailor a photocatalytic system which not only avoids the use of
765 electron mediators but also offers significant photocatalytic ability under different reaction
766 conditions. The latest third generation of Z-scheme i.e. direct Z-scheme photocatalytic systems
767 seem to be an effective approach to overcome all the drawback associated with ASS Z-scheme
768 and provide appropriate redox potential for H₂ generation as well as for CO₂ reduction.

6. Direct Z-scheme photocatalysts

771 Direct ~~Z-Scheme-scheme~~ nanohybrids were primarily introduced in 2013 which comprised of
772 two semiconductor photocatalysts forming a compact surface junction and neglecting the
773 requirement of Transmission Bridge for migration of electrons [134-136]. In comparison with
774 traditional Z-scheme (generation I with redox mediator), direct Z-scheme system conquer
775 backward reactions due to absence of redox mediators. Moreover, the shielding effect produced
776 by charge carrier mediators (A/D pairs) is also effectively reduced. Furthermore, in contrast with
777 ASS Z-scheme systems involving solid electron mediator, there ~~is-are~~ no expensive and photo-
778 corrosive metals included in direct Z-scheme system. In addition, the transmission distance for
779 electron transfer gets remarkably decreased due to the absence of electron migration bridge
780 formed by solid-state mediators. Although the structure of both type-II and direct ~~Z-Scheme~~
781 ~~scheme~~ system is similar yet their charge transfer mechanism is totally different as ascertain by
782 various characterization methods [137, 138]. As mentioned before, in direct Z-scheme system
783 the spatial separation of EHP follows inter cross-sectional electron transfer mechanism
784 stimulated by the induced electric field at the interfacial junction, totally different from
785 conventional heterojunction photocatalysts. Both semiconductors (SC-I and SC-II) under visible
786 light illumination, generates EHP which undergo inter-~~cross-cross~~-sectional electron transfer via
787 transference of e_{CB}^- present in SC-II to VB of SC-I and combines with holes. Eventually, e_{CB}^- on
788 SC-I and h_{VB}^+ of SC-II are spatially separated with high redox potential values than the potential
789 for radical's production (-0.33 V and +2.4 V vs. NHE for $\bullet O_2^-$ and $\bullet OH$ radicals, respectively).
790 Also, through direct Z-scheme migration pathway of photogenerated EHP, the photon shielding
791 problem induced due to redox mediators is effectively overcome resulting in higher absorption of
792 visible light by semiconductor photocatalysts.

1
2
3
4 793 For instance, Low *et al.* smartly designed reusable TiO₂/CdS direct Z-scheme heterojunction
5
6 794 system and evaluate its potential for photoassisted CO₂ reduction into methane [139]. The
7
8 795 formation of an intact surface junction between TiO₂ and CdS as a result of direct Z-scheme
9
10 796 coupling was investigated with in-situ irradiated X-ray photoelectron spectroscopy (ISI-XPS) as
11
12 797 shown in Fig. 11a and b. Precisely, after the exposure of light, the slight positive shift in binding
13
14 798 energy (by 0.3 eV) of Ti 2p peaks were observed owing to decreased electron density. Besides,
15
16 799 under the same conditions, Cd 3d peaks exhibited negative shift by -0.2 eV due to increased
17
18 800 electron density on CdS. These in-situ results depicted significant transference of electrons from
19
20 801 TiO₂ to CdS under visible light illumination suggesting the formation of direct Z-scheme system
21
22 802 instead of conventional type-II heterojunction. Such in-situ experimental observations provide an
23
24 803 effective insight into the mechanistic pathway of charge carrier's migration and separation. In
25
26 804 another study, a novel Z-scheme 2D/2D MnIn₂S₄/g-C₃N₄ (MnISCN) nanocomposite was
27
28 805 prepared by hydrothermal route followed by in-situ loading of MnIn₂S₄ (MnIS) nanoflakes on g-
29
30 806 C₃N₄ (CN) nanosheets [140]. Photoactivity of the system was assessed for TC degradation and
31
32 807 H₂ production. X-ray diffraction (XRD) study supported the formation of an intact phase
33
34 808 structure of MnISCN-20 system providing excellent constancy and durability of MnISCN
35
36 809 nanocomposite. Furthermore, H₂ evolution ability of obtained photocatalyst was determined
37
38 810 under visible light irradiation in an aqueous solution containing 0.25 M Na₂SO₃ and 0.35 M
39
40 811 Na₂S. Bare CN and MnIS exhibited weak photocatalytic activity for H₂ generation with an
41
42 812 average efficacy of 24.5 μmol g⁻¹ h⁻¹ and 58.3 μmol g⁻¹ h⁻¹, respectively. Besides, MnISCN-20
43
44 813 photocatalyst displayed substantial photocatalytic efficiency of 200.8 μmol g⁻¹ h⁻¹ which was
45
46 814 about 3.5 times more than MnIS nanoflakes. The UV-Vis DRS results displayed that valance
47
48 815 band maximum (VBM) of CN nanosheets and MnIS nanoflakes were at 2.35 eV and 1.15 eV,
49
50 816 respectively. While, conduction band minimum (CBM) for CN nanosheets and MnIS nanoflakes
51
52 817 were calculated to be at -0.58 eV and -0.74 eV, respectively. Thus, the narrow-band gaps of both
53
54 818 the photocatalysts facilitate visible light absorption leading to band-to-band transition of
55
56 819 photocarriers. It was found that production of •OH radical was not feasible due to more negative
57
58 820 VB edge (+1.15 eV vs. NHE) of MnIS than the standard redox potential of •OH/H₂O (+1.99 eV
59
60 821 vs. NHE), moreover, CB edge value of CN (-0.58 eV vs. NHE) was more positive as compared
61
62 822 to standard potentials of O₂/H₂O₂ (-0.695 eV vs. NHE). Hence, Z-scheme charge transfer
63
64 823 mechanism was framed in which the photoexcited electrons get migrated from CB of CN to VB
65

1
2
3
4 824 of MnIS generating photoexcited EHP with enhanced redox abilities to produce •OH radicals as
5
6 825 shown in (Fig. 11d). Evidently, ~~†~~ typical double transfer mechanism (Fig. 11c) is excluded which
7
8 826 is in accordance ~~to~~ with PL, ESR and trapping experiments. Thus, with the formation of the
9
10 827 intact surface junction, direct Z-scheme heterojunction system endows superior optoelectronic
11
12 828 properties which are in agreement with assorted characterisation techniques.

13
14
15 829 Other than binary nanocomposites, g-C₃N₄ based ternary novel Z-scheme heterojunction g-
16
17 830 C₃N₄/MoS₂/Ag₃PO₄ (CMA) was successfully designed for O₂ evolution under white light
18
19 831 illumination [141]. By exfoliation, highly conductive 2D MoS₂ nanoflakes and altered g-C₃N₄
20
21 832 nanosheets were concurrently coupled with Ag₃PO₄ (silver orthophosphate) resulting in a ternary
22
23 833 direct Z-scheme CMA heterojunction system for enhanced O₂ production through OWS. The
24
25 834 CMA composites with distinct MoS₂ amount showed significant variation in photocatalytic
26
27 835 performances. Out of all the prepared CMA composites, CMA-20 composite (CMA composite
28
29 836 with 20 mg MoS₂ loading) attributed best photocatalytic water oxidation efficacy. SEM analysis
30
31 837 illustrated that large amounts of ECN nanosheets and MoS₂ were dispersed over uniform Ag₃PO₄
32
33 838 particles. From DRS plots, the band-gap of MoS₂ nanosheets was determined to be 1.72 eV.
34
35 839 Furthermore, CB and VB edge potential were estimated to be at -0.1 V and 1.71 V, respectively.
36
37 840 Based on these potential values, the photocarriers migration pathway was direct Z-scheme as
38
39 841 illustrated in (Fig. 11e). Under simulated visible light illumination, photoexcited CB electrons in
40
41 842 Ag₃PO₄ get transmitted to VB of MoS₂ and combines with photogenerated holes. Besides, photo-
42
43 843 induced CB electrons in MoS₂ migrated and combined with VB holes of g-C₃N₄, leaving behind
44
45 844 active holes in Ag₃PO₄ along with electrons in CB of g-C₃N₄ for effective photo-illuminated
46
47 845 water splitting. In CMA nanocomposite, the presences of highly conductive MoS₂, exceptionally
48
49 846 boost the photocarriers transfer efficacy by suppressing photogenerated EHP.

50
51
52 847 <Please Insert Fig. 11 Here>

53
54 848 Summarily, tailoring direct Z-scheme photocatalytic system with appropriate semiconductor
55
56 849 photocatalysts is an effective strategy to overcome various environmental and energy issues.
57
58 850 Since, direct Z-scheme photocatalytic systems hold great potential for superior migration and
59
60 851 separation of photocarriers while maintaining the apt redox ability of the system. However,
61
62 852 several challenges involving effectual solar light harvesting, high physicochemical stability, the

1
2
3
4 853 formation of intact surface junction and utilization of proper characterization techniques ~~in order~~
5
6 854 to investigate the charge migration pathways still needs improvement. Nevertheless, with
7
8 855 breakthrough discoveries and an ever-growing number of publications in this area, it is evident
9
10 856 that direct Z-scheme systems fan the flame in photocatalytic water splitting as well as CO₂
11
12 857 reduction applications.

14 858 **7. Applications of Z-scheme photocatalytic systems**

17 859 *7.1 Photocatalytic CO₂ reduction*

18 860 As the efforts of researchers on photoassisted CO₂ reduction increases, new directions and
19
20 861 tendencies emerges. Recent reports display certain common perspectives of designing and
21
22 862 tailoring Z-scheme photocatalytic systems in order to stimulate high photo to functional energy
23
24 863 conversion efficacy with high product selectivity. Since, photocatalytic Z-scheme setup involves
25
26 864 two different semiconductor materials to bring about dual excitation after visible light exposure
27
28 865 and efficaciously separate photocarriers. Thus, photocatalytic CO₂ reduction into useful fuels
29
30 866 utilizing Z-scheme photocatalytic systems seems as like a beneficial technique for
31
32 867 contemporaneous environmental remediation and partly-partial fulfilment of energy requirements
33
34 868 [142-149]. However, designing of Z-scheme photosystems with utmost selectivity of products in
35
36 869 case of CO₂ reduction is very crucial. For instance, Jo *et al.* rationally tailored Bi₂WO₆/RGO/g-
37
38 870 C₃N₄ (BWO/RGO/CN) nanocomposite for photoassisted CO₂ reduction into CO and CH₄ [150].
39
40 871 The as-tailored ASS Z-scheme photocatalyst containing 15 wt% BWO and 1 wt% RGO
41
42 872 displayed remarkable efficiency in the photoreduction of CO₂ with notable selectivity of 92%
43
44 873 against H₂ production. The unique assembly of 2D photocatalytic materials along with the dual
45
46 874 role of RGO (electron capture and redox mediator) in ASS Z-scheme system played a leading
47
48 875 role in photoactivity enhancement. To scrutinize the CO₂ reduction efficiency of the
49
50 876 aforementioned system, experiments utilizing pristine ~~as well as binary samples of BRC-15 PM~~
51
52 877 ~~(a mixture containing RGO-1 wt%, CN and BWO-15 wt%) and commercial P25 catalyst, as~~
53
54 878 well as binary samples of BRC-15 PM (a mixture containing RGO- 1 wt%, CN and BWO- 15
55
56 879 wt%) and commercial P25 catalyst, were performed as depicted in Fig. 12a. Clearly,
57
58 880 BWO/RGO/CN ASS Z-scheme system exhibited superior photoreduction efficiency which was
59
60 881 ascribed to the synergistic effect between 2D components of the heterojunction. Besides, the
61
62 882 photocatalytic system also showed improved H₂ evolution with 185 μmol quantum yield which

1
2
3
4 883 was far better than pristine and binary samples. Furthermore, to investigate the effectiveness of
5
6 884 space charge separation ~~as well as the dual functionality of RGO, transient photocurrent analysis,~~
7
8 885 as well as the dual functionality of RGO, transient photocurrent analysis, was utilized. From Fig.
9
10 886 12b the photocurrent responses of different photocatalysts during five on-off cycles of
11
12 887 intermittent light exposure can be seen. ~~Evidently, a~~ All the BWO/RGO/CN nanocomposites
13
14 888 exhibited better photocurrent responses in contrast with other photocatalysts suggesting a
15
16 889 superior separation of photocarriers in the composite. Notably, the photocurrent results were well
17
18 890 consistent with the PL as well as photocatalytic analysis. The proposed Z-scheme charge transfer
19
20 891 mechanism of BWO/RGO/CN for photoassisted CO₂ reduction is depicted in Fig. 12c. Through
21
22 892 Z-scheme charge transfer mode containing RGO as the transmission bridge, the photoinduced
23
24 893 holes were accumulated on VB of BWO while the photoexcited electrons were collected at CB
25
26 894 of CN. As a result, the VB holes of BWO reacted with water to produce O₂ and protons while the
27
28 895 CB electrons of CN after returning to RGO interacted with adsorbed CO₂ to produce CO₂^{·-}
29
30 896 radicals which in turn generated CO, CH₄ and H₂. Moreover, due to synergistic effect of BWO,
31
32 897 RGO and CN in the photocatalytic system the reassembly of photocarriers was drastically
33
34 898 decreased resulted in increased electron density on the system which effectively facilitated the
35
36 899 formation of CH₄ and CO.

35 900 <Please Insert Fig. 12 Here>

37 901 Till date, various photocatalytic systems utilizing photosensitive AgCl in Z-scheme
38
39 902 photocatalysts have been explored due to their unique property of switching from Ag⁺ to metal
40
41 903 Ag⁰ which facilitate the space **isolation** of photocarriers. Besides, due to appropriate band edge
42
43 904 positioning of AgCl (E_{VB} = 3.19 eV and E_{CB} = -0.05 eV), it can be coupled with reductive g-
44
45 905 C₃N₄ photocatalyst in Z-scheme mode to stimulate the photoassisted reduction of CO₂. Keeping
46
47 906 that in mind, Murugesan *et al.* tailored a novel direct Z-scheme AgCl@g-C₃N₄ nanohybrid by
48
49 907 loading different AgCl ratios on g-C₃N₄ through improved deposition-precipitation synthesis
50
51 908 route [151]. Remarkably, the wide band-gap of AgCl (3.26 eV) obstructed visible light
52
53 909 absorption but localised SPR effect in Ag⁰ facilitated absorption of light leading to the generation
54
55 910 of photocarriers. Also, PL studies supported the heterojunction formation between AgCl and g-
56
57 911 C₃N₄ resulting in suppressed recombination of photoinduced EHP. Notably, the PL emission
58
59 912 intensity of aforementioned photocatalytic system decreased with the presence of AgCl in the
60
61 913 composite suggesting the formation of intact surface junction which effectively inhibited the

1
2
3
4 914 reassembly of EHP. Detailed synthesis and charge migration route is-are explicated in (Fig. 13).
5
6 915 Proposed Z-scheme mechanism of 1%AgCl@g-C₃N₄ elucidated that accumulated
7
8 916 photogenerated electrons on AgCl surface combine directly with VB holes of g-C₃N₄ suppressing
9
10 917 EHP recombination. Further, photo-illuminated CB electrons of g-C₃N₄ owing sufficient
11
12 918 potential can reduce CO₂ into methane, acetic acid and formic acid as confirmed through gas
13
14 919 chromatography analysis. The mechanistic reactions involving the photoreduction of CO₂ is as
15
16 920 follows:

24 925
25
26 926 **<Please Insert Fig. 13 Here>**
27
28 927

29
30 928 Thus, the unique combination of semiconductors with complimentary band edge positioning to
31
32 929 extend visible light absorption and to improve the redox ability of photocatalytic systems *via*
33
34 930 efficient charge isolation can substantially enhance the photoreduction efficacy of CO₂.

35
36 931 In another study, Xu and his peer group designed a ternary Ag₂CrO₄/g-C₃N₄/GO nanocomposite
37
38 932 (CAG) using a photosensitizer (Ag₂CrO₄) and a cocatalyst (GO) for CO₂ reduction into CH₃OH
39
40 933 and CH₄ [152]. Less particle size of Ag₂CrO₄ facilitated its combination with N-H groups
41
42 934 present on the wrinkled g-C₃N₄ surface *via* co-ordination bond. As a result, the strong junction
43
44 935 was established between g-C₃N₄ and Ag₂CrO₄ which in turn boosted space separation of
45
46 936 photocarriers. The as-synthesised CAG photocatalyst displayed improved photocatalytic
47
48 937 efficiency for CO₂ conversion with 0.30 h⁻¹ turnover frequency (2.3 × ~ g-C₃N₄). Similar band
49
50 938 structure along with suitable loading ratio of Ag₂CrO₄ helped to construct direct Z-scheme
51
52 939 heterojunction stimulated by an internal electric field (IEF) across Ag₂CrO₄/g-C₃N₄ junction
53
54 940 resulting in CO₂ adsorption and subsequent reduction (Fig. 14a). Also, the addition of GO as
55
56 941 cocatalyst endorsed charge transfer along with plentiful adsorption and catalytic sites for CO₂.
57
58 942 Since, the 2D porous network structure of GO containing -COOH and -OH groups stimulated
59
60 943 the transportation as well as binding of CO₂ molecules. To investigate the effectiveness of charge
61
62 944 migration and separation through Z-scheme mode, fluorescent spectroscopy along with

1
2
3
4 945 photocurrent measurements were carried out. Evidently, ~~t~~The ternary composite displayed
5
6 946 weakest PL emission intensity which was attributed to the exceptional electron sink behaviour of
7
8 947 GO resulted in inhibited direct recombination of photocarriers. Besides, the photocurrent
9
10 948 analysis of ternary CAG photocatalyst also indicated the efficacious charge separation in the
11
12 949 sample by showing the highest photocurrent response than that of pristine and binary samples.
13
14 950 Upon visible light illumination and under the effect of IEF, CB electrons of Ag₂CrO₄ combined
15
16 951 with photoinduced VB holes of g-C₃N₄ with an accumulation of electrons and holes in CB of g-
17
18 952 C₃N₄ and VB of Ag₂CrO₄, respectively. Photoinduced CB electrons of g-C₃N₄ with sufficient
19
20 953 potential reduced CO₂ into functional fuels like CH₃OH and CH₄ whilst, photogenerated VB
21
22 954 holes of Ag₂CrO₄ reacted with water to produce O₂. Besides, lower GO potential (-0.49 V vs.
23
24 955 NHE, pH = 7) than g-C₃N₄ was a thermodynamically favourable condition for migration of CB
25
26 956 electrons of g-C₃N₄ onto the conductive network surface of GO. Thereby, CAG ternary
27
28 957 nanocomposite displayed improved photocatalytic CO₂ conversion efficiency because of the
29
30 958 effective synergetic outcome of Ag₂CrO₄, g-C₃N₄ and GO. Thus, it is quite evident that by
31
32 959 combining plasmonic semiconductor photocatalyst with carbonaceous electron sink materials
33
34 960 synergy between extended light absorption and charge separation can be achieved leading to
35
36 961 boosted photocatalytic efficacy.

35
36 962 It has been widely reported that the transition metal oxides with broad-band edge positioning
37
38 963 contains partly filled d-orbitals which extend the absorption of light in the visible region due to
39
40 964 d-d transitions [153]. Typically, MnO₂ with partly filled d-orbitals is a prominent transition metal
41
42 965 oxide semiconductor photocatalyst having fascinating features like economic, abundance,
43
44 966 superior physicochemical stability and environmental friendly. Moreover, due to the multiple
45
46 967 valances of MnO₂, it can act as a semiconductor photocatalyst which can effectively enhance the
47
48 968 visible light absorption as well as photoactivity after coupling with reductive g-C₃N₄. For
49
50 969 example, Wang *at el.* designed MnO₂/g-C₃N₄ nanocomposite via facile in-situ oxidation-
51
52 970 reduction reaction comprising KMnO₄ and MnSO₄.H₂O absorbed on the g-C₃N₄ surface [154].
53
54 971 The as-obtained enhanced CO₂ reduction efficacy was accredited to synergetic catalytic effect
55
56 972 developed during heterojunction construction between MnO₂ and g-C₃N₄. Moreover, the
57
58 973 interface bonding between Mn²⁺ and ubiquitously present NH₂ functional groups on g-C₃N₄
59
60 974 surface boosted the spatial separation of photocarriers. Also, through ohmic contact developed at
61
62 975 the interface, the photogenerated CB electrons of MnO₂ shifted to the VB of g-C₃N₄ (Fig. 14b)

1
2
3
4 976 provided effective space charge separation. Besides, CB electrons of g-C₃N₄ reacted with
5
6 977 absorbed CO₂ under the influence of protons to generate CO and H₂O. To further elucidate the
7
8 978 charge migration and effective separation, electrochemical impedance spectroscopy (EIS)-~~as well~~
9
10 979 ~~as photocurrent responses, as well as photocurrent responses,~~ were examined. It was observed
11
12 980 that the MnO₂/g-C₃N₄ nanohybrid exhibited exceedingly enhanced photocurrent density in
13
14 981 contrast with bare g-C₃N₄ indicated highly suppressed reassembly and effective separation of
15
16 982 EHP. Thus, the notable features like: matched band alignments, improved visible light
17
18 983 harvesting and synergistic interactions between MnO₂ and g-C₃N₄ due to solid C-O bonding at
19
20 984 the surface junction substantially incremented the photoassisted conversion of CO₂ into CO.
21
22 985 As a whole, a large number of semiconductor photocatalysts have been developed lately ~~in-order~~
23
24 986 to get the optimal photocatalytic CO₂ conversion efficiency. However, with the present scenario
25
26 987 of photocatalytic materials and photo-efficiency, the photoassisted reduction of CO₂ cannot be
27
28 988 implemented on an industrial scale. The improved results obtained from Z-scheme photocatalysis
29
30 989 involving fascinating reductive type g-C₃N₄ semiconductor seems to be a good approach to attain
31
32 990 widespread applications. However, the selection of adjoining semiconductor photocatalyst,
33
34 991 design of photoreactor and selective reduction of CO₂ into functional hydrocarbon fuels still
35
36 992 require more attention by researchers.

37 993 **<Please Insert Fig. 14 Here>**

38 994

39 995 *7.2 Photocatalytic water splitting*

40
41 996 Photocatalytic water splitting is vital ~~in-order~~ to meet desirable energy source, without reckoning
42
43 997 on fossil reserves [155-163]. However, even after breakthrough discoveries in photocatalysis, H₂
44
45 998 generation through photoassisted water splitting utilizing semiconductor materials is still far
46
47 999 from the reach of ~~pilot-pilot~~-scale applications. In order to improve the visible light harnessing
48
49 1000 along with resultant photo_efficiency ~~a-number-of_several~~ strategies involving texture
50
51 1001 engineering, bandgap modifications, incorporation of co-catalyst and so on, have been
52
53 1002 developed. So far, mimicking natural photosynthesis to form artificial Z-scheme photocatalysis
54
55 1003 empowers efficient solar energy utilization for photocatalytic H₂ generation through water
56
57 1004 splitting. In that regard, metal-free 2D reductive type g-C₃N₄ promptly becomes a promising
58
59 1005 candidate for photocatalytic H₂ generation due to its exceptional **physicochemical** features.
60
61 1006 Hybridising g-C₃N₄ with another metal-free semiconductor photocatalyst to form a Z-scheme
62
63
64
65

1
2
3
4 1007 heterojunction system can effectively impart high photocarriers separation efficacy along with
5
6 1008 superior redox ability to enhance the overall photoactivity. For example, innovative work by
7
8 1009 Wang *et al.* anticipated two ~~metal-metal~~-free C₃N/g-C₃N₄ nanocomposites in which g-C₃N₄ sheet
9
10 1010 (single layer/bilayer) was concealed with monolayer C₃N [164]. Investigations revealed that the
11
12 1011 band bending caused by strong internal electric fields at the respective interface region of
13
14 1012 photocatalysts facilitate the migration of photocarriers through Z-scheme rather than type-II
15 1013 route. A proposed direct Z-scheme mechanism for OWS (Fig. 14c) explicates photoexcited CB
16
17 1014 electrons of C₃N monolayer possess sufficient potential for HER while VB holes of g-C₃N₄ are
18
19 1015 used to oxidise H₂O into O₂. From experimental results, it was observed that due to migration of
20
21 1016 photoinduced electrons from C₃N to monolayer or bilayer g-C₃N₄ sheet, strongly ~~built-built~~-in
22
23 1017 electric field was induced which caused band bending in C₃N and g-C₃N₄ sheets upward and
24
25 1018 downward, respectively. Consequently, the CB edge potential of C₃N monolayer and VB edge of
26
27 1019 g-C₃N₄ in the nanocomposite were suitable enough with the photocatalytic water redox
28
29 1020 potentials. Moreover, the synergistic effect induced due to coupling of two ~~metal-metal~~-free 2D
30 1021 materials facilitated the harnessing of visible light from visible to NIR region.

31
32 1022 The concept of hydrogen evolution through water decomposition using Z-scheme photocatalysis
33
34 1023 is a ground-breaking strategy for the sustainable and eco-friendly method for energy
35
36 1024 development [165-174]. However, the key concern of tailoring a Z-scheme photocatalytic system
37
38 1025 involves the semiconductor photocatalysts with well-matched band alignments best suited for
39
40 1026 water redox potentials. Coupling g-C₃N₄ with TiO₂ serves as a great deal since, there band edge
41
42 1027 positions match well together. Besides, the involvement of Au NPs as a solid electron mediator
43
44 1028 with dual functionality to act as a photosensitizer as well as their ability of SPR effect can
45
46 1029 significantly boost the photocatalytic H₂ generation. ~~Best~~ The best example in this regard is the
47
48 1030 work by Zou *et al.* who engineered g-C₃N₄/Au/C-TiO₂ hollow spheres as ASS Z-scheme
49
50 1031 photocatalyst with Au NPs as solid-state electron mediator [175]. Upon solar light illumination,
51
52 1032 incremented photocatalytic efficacy of g-C₃N₄/Au/C-TiO₂ nanocomposite was evaluated for H₂
53
54 1033 production. It was reported that incorporation of Au NPs as electron mediator facilitated the
55
56 1034 absorption of light in visible range due to SPR effect. From HR-TEM experiments, presence of
57
58 1035 Au NPs in the heterojunction system was evaluated where the lattice fringes with d-spacing of
59
60 1036 0.35 nm ((001) facet of anatase TiO₂) and 0.24 nm ((111) facet of Au) were observed. On the
61
62 1037 other hand, C-doping introduced a mid-gap state near the VB of TiO₂ extending light absorption
63
64
65

1
2
3
4 1038 to longer wavelength. PL studies indicated that •OH radicals were the leading ROS for
5
6 1039 photocatalytic H₂ evolution which is possible only through the Z-scheme migration pathway.
7
8 1040 Since, through the double-charge migration route, the redox potential of the system was not
9
10 1041 sufficient enough for the generation of •OH radicals in the majority. The proposed ASS Z-
11
12 1042 scheme charge transfer mode illustrating the band alignments of g-C₃N₄, Au and C-doped TiO₂
13
14 1043 is depicted in Fig 15a. The electrons from CB of C-TiO₂ migrated through Au NPs to VB of g-
15
16 1044 C₃N₄ and combined with holes. Simultaneously, photogenerated CB electrons in g-C₃N₄ reduced
17
18 1045 H⁺ to H₂ besides VB holes of C-TiO₂ oxidized sacrificial agents into products. As a result, the
19
20 1046 aforementioned nanocomposite exhibited superior photoassisted H₂ evolution rate which was 42
21
22 1047 and 86 times higher than that of g-C₃N₄ and C-TiO₂, respectively. Thus, efficient visible light
23
24 1048 harnessing, superior redox ability and effectual migration/separation of photocarriers through
25
26 1049 ASS g-C₃N₄/Au/C-TiO₂ nanocomposite synergistically stimulated the photocatalytic efficacy.
27
28 1050 In summary, **the** reductive type g-C₃N₄ with appropriate CB and VB edge potentials is
29
30 1051 undoubtedly a fascinating semiconductor photocatalyst in Z-scheme water splitting applications.
31
32 1052 Also, the coupling of g-C₃N₄ with an appropriate photocatalyst in order to form a Z-scheme
33
34 1053 hybrid is a promising tactic to boost its photoassisted water splitting performance. Various direct
35
36 1054 Z-scheme photocatalysts with their photocatalytic abilities for H₂ generation and CO₂ reduction
37
38 1055 are ~~summarised~~ summarized in Table. 2.

39 1056 **<Please Insert Fig. 15 Here>**

40 1057

41 1058 7.3. Other applications

42
43 1059 Although dinitrogen (N₂) is the most abundant gas in the atmosphere, yet ‘fixed’ nitrogen form
44
45 1060 bioavailability for living organisms is minimal [176]. In order to fulfil these necessities, nitrogen
46
47 1061 fixation under mild conditions is essential since artificial N₂ fixation through the Haber-Bosch
48
49 1062 process involves high energy involvements. Thus, developing advanced strategies which involve
50
51 1063 green and sustainable energy sources is highly desired. Photocatalytic N₂ fixation utilizing never
52
53 1064 lasting solar energy is a green and economical technique for the conversion of N₂ into NH₃ [177,
54
55 1065 178]. For example, Cao *et al.* described aromatic rings of 3, 4-dihydroxybenzaldehyde (DBD) as
56
57 1066 an electron mediator in Ga₂O₃/graphitic carbon nitride (Ga₂O₃-DBD/g-C₃N₄) ASS Z-scheme
58
59 1067 heterojunction for solar light assisted photocatalytic nitrogen fixation [179]. The as-tailored
60
61 1068 nanocomposites were found to exhibit high photocarriers separation efficacy, improved visible-

1
2
3
4 1069 light absorption along with high redox capacity due to the formation of a conductive interface
5
6 1070 between Ga₂O₃-DBD and g-C₃N₄. The proposed charge migration mechanism in relevance with
7
8 1071 experimental results was Z-scheme mode with DBD rings as electron mediator instead of typical
9
10 1072 type-II as illustrated in (Fig. 15b). Spin trapping electron paramagnetic resonance (EPR)
11
12 1073 technique confirmed •CO₂⁻ as the main active species responsible for N₂ fixation (Fig. 15c).
13
14 1074 Moreover, the facile generation of •CO₂⁻ (E₀ = 1.8V) radicals with sufficient potential prompted
15 1075 the photoassisted reduction of N₂ to NH₃. The photocurrent measurements observed for 2.4%
16
17 1076 Ga₂O₃-C₃N₄ and 2.4% Ga₂O₃-DBD/g-C₃N₄ are depicted in Fig. 15d. It can be ~~clearly~~ seen that
18
19 1077 the photocurrent response of 2.4% Ga₂O₃-DBD/g-C₃N₄ was observed to be much higher than
20
21 1078 that of 2.4% Ga₂O₃-C₃N₄, suggesting the superior space charge separation due to the
22
23 1079 construction of Z-scheme involving DBD rings as the electron mediator. Due to Z-scheme
24
25 1080 charge migration route, high potential photogenerated CB electrons of g-C₃N₄ converted O₂ to
26
27 1081 H₂O₂ while VB holes of Ga₂O₃ with sufficient redox potential generated •OH radicals from H₂O.
28 1082 Furthermore, •OH radicals reacted with CH₃OH to produce •CO₂⁻ which facilitated the reduction
29
30 1083 of N₂ to NH₃.

31
32 1084 **<Please Insert Fig. 15 Here>**

33
34 1085 In another work, Liu and his team reported the facile fabrication of porous g-C₃N₄ loaded with
35
36 1086 Fe₂O₃ for the photocatalytic conversion of N₂ to ammonia [180]. Coupling g-C₃N₄ (porous) with
37
38 1087 Fe₂O₃ substantially incremented the photocatalytic N₂ reduction rate driven by artificial solar
39 1088 light. Of note, the g-C₃N₄/Fe₂O₃ (< 1 wt%) (GF) nanocomposite exhibited 47.9 mg/L/h rate of
40
41 1089 photocatalytic production NH₃ from N₂ reduction which was about 6 times higher than pristine
42
43 1090 g-C₃N₄. To examine the photocatalytic activities of GF composites annealed at different
44
45 1091 temperatures for the photoassisted reduction of N₂, the experiments were performed in a water
46
47 1092 system with bubbling N₂ atmosphere under the exposure of 300 W Xe lamp. And the rate of **NH₃**
48 1093 **production** by different GF composites is depicted in Fig. 16a. The **investigation further** revealed
49
50 1094 that the GF composite annealed at 500 °C (GF-500) exhibited an exceedingly high rate of NH₃
51
52 1095 generation (47.9 mg/L/h) which significantly decreased after an additional increase in annealing
53
54 1096 temperature, suggesting the importance of Fe₂O₃ in the composite. Moreover, the photocurrent
55
56 1097 responses also suggested that the GF composites exhibited higher photocurrent intensity due to
57
58 1098 the effectual separation of photocarriers (Fig. 16b). The GF-500 composite displayed
59 1099 photocurrent intensity of 4.5 × 10⁻⁶ A which was much higher than that of g-C₃N₄ (1.0 × 10⁻⁶ A).
60
61
62
63
64
65

1
2
3
4 1100 Furthermore, the possible Z-scheme charge transfer pathway is depicted in Fig. 16c. Because of
5
6 1101 suitable band edge positioning, the photo-excited CB electrons of Fe₂O₃ rapidly combine with
7
8 1102 VB holes of g-C₃N₄ and form a Z-scheme system. Due to Z-scheme charge transfer mode,
9
10 1103 effectual space charge separation was attained resulted in ~~well-well~~-maintained redox abilities
11
12 1104 suitable for photocatalytic N₂ reduction.

13
14 1105 <Please Insert Fig. 16 Here>

15 1106 Other than energy conversion applications, photocatalysis is in constant limelight for
16
17 1107 environmental remediation involving biotic and abiotic pollutant degradation, noxious gases
18
19 1108 removal and harmful electromagnetic waves absorber [181-185]. Thus, with consistent research
20
21 1109 efforts in the field of photocatalysis, more efficient semiconductor materials with high stability,
22
23 1110 recyclability, non-toxicity and extended visible spectral response can be designed with critical
24
25 1111 significance in both theory and practice.

26 1112

28 1113 8. Conclusion and viewpoint

29
30 1114 The discussion in the present review highlights the photoassisted energy conversion applications
31
32 1115 that could provide a light of hope to overcome the energy issues rising globally. Selecting an
33
34 1116 appropriate photocatalytic material which fulfils all the imperative criteria is of utmost concern.
35
36 1117 Architecting visible light stimulated Z-scheme photocatalysts is in rife attention by dint of its
37
38 1118 great potential in various photocatalytic applications that aids to serve as a promising aspirant for
39
40 1119 solar light harvesting and environmental restoration. As explained in a review of literature,
41
42 1120 fascinating properties of reductive type g-C₃N₄ like its tunable electronic structure and first-rate
43
44 1121 physicochemical stability complements its coupling with other semiconductor materials with
45
46 1122 appropriate band potentials ~~in-order~~ to achieve improved photoactivity. This review encircles far-
47
48 1123 reaching aspects of recent research work on all solid state and direct Z-scheme photocatalysis
49
50 1124 inspired by artificial photosynthesis together with its captivating applications like CO₂ reduction,
51
52 1125 photocatalytic water splitting and nitrogen fixation (Fig. 17). Construction of Z-scheme
53
54 1126 photocatalysts involving reduction type photocatalysts has some characteristic qualities which
55
56 1127 extend its application in various pitches as:

57 1128 (1) To attain water splitting, Z-scheme system involving reduction type photocatalysts has
58
59 1129 overruled conventional double transfer system by outspreading wavelength towards NIR to offer
60
61 1130 maximum optical absorption along with improved redox ability. Furthermore, the Z-scheme

1
2
3
4 1131 photocatalytic system is capable to encompass both half-cell reactions deprived using sacrificial
5
6 1132 reagents for water splitting.

7
8 1133 (2) For photocatalytic CO₂ reduction, constructing reduction type g-C₃N₄ based Z-scheme
9
10 1134 photocatalytic system provides efficiently high redox ability. Since g-C₃N₄ is a reduction type
11
12 1135 photocatalyst moreover existence of ubiquitous -NH and -NH₂ Lewis basic groups provide
13
14 1136 effective absorption sites for CO₂ along with the generation of photocarriers for its reduction.

15 1137 (3) Tailoring of Z-scheme systems which include reductive photocatalysts render sufficient
16
17 1138 catalytic surface sites, improved generation of ROS and suppressed EHP recombination which
18
19 1139 boosts the overall photocatalytic efficacy.

20
21 1140 (4) Integrating g-C₃N₄ with a suitable photocatalytic material which offers SPR effect is of great
22
23 1141 potential as it extends visible light harnessing ability of Z-scheme system. As a result, the Z-
24
25 1142 scheme mode synergistically improves optical response along with charge carrier isolation
26
27 1143 efficiency.

28 1144 (5) Involvement of carbonaceous material as electron sink provides additional help to boost the
29
30 1145 charge carrier's kinetics and enhance the availability of electrons to participate in photo-redox
31
32 1146 reactions.

33
34 1147 <Please Insert Fig. 17 Here>

35 1148 • *Current scenario*

36
37 1149 To date, Z-scheme photocatalysis is a developing strategy as it provides superior photocatalytic
38
39 1150 efficacy over traditional double charge transfer mechanism. The reason of improved
40
41 1151 photoactivity is ascribed by its ability to generate photo-illuminated charge carriers, their
42
43 1152 effective spatial separation, more catalytic surface sites, the formation of active species, a
44
45 1153 prolonged life-time of ROS and enhanced redox abilities by using two photocatalysts. However,
46
47 1154 the first and second generation of Z-scheme photocatalysis has some pitfalls which restrict their
48
49 1155 widespread applications. In detail, traditional or liquid-phase Z-scheme photocatalysts use liquid
50
51 1156 state redox mediators which undergo thermodynamically favourable backward reactions
52
53 1157 resulting in low photoactivity. Moreover, in the second generation of the Z-scheme system, use
54
55 1158 of noble-metals as solid-state electron mediators not only renders visible light absorption but is
56
57 1159 also photo-corrosive which affect the photocatalytic efficiency. In ASS Z-scheme system,
58
59 1160 optimal modification in the geometrical configuration is the most desirable strategy to boost the
60
61 1161 photocatalytic performance. On the other hand, various efforts in-in-band modification of direct

1
2
3
4 1162 Z-scheme photocatalysis unleashed its inside out properties. Still, significant efforts by
5
6 1163 researchers are underway to architect more efficient systems of this type.

7
8 1164 • *Challenges and outlook for researchers*

9
10 1165 In Z-scheme systems, a rational assortment of photocatalytic material is protagonist among all
11
12 1166 other conditions. Choosing an appropriate semiconductor material with apt band edge potentials
13
14 1167 is of foremost importance along with some other ‘nuts-and-bolts’;

- 15 1168 (1) Semiconductors with narrow band-gap and sufficient redox sites are favourable for the
16
17 1169 development of Z-scheme photocatalysis as it expedites harnessing of visible light and
18
19 1170 generation of active species for various oxidation/reduction reactions.
- 20
21 1171 (2) Morphological features also play an important role in active species generation as
22
23 1172 semiconductor materials with ultrathin structure accelerates the diffusion of
24
25 1173 photoinduced carriers onto the semiconductor surface and stimulates redox reactions.
- 26 1174 (3) Alongside, fabrication of new coupled systems hinge on rational interface-engineering
27
28 1175 methodologies is an additional tactic that should be taken into account. In direct Z-
29
30 1176 scheme systems establishment of surface phase junction between two photocatalysts
31
32 1177 plays a key role in space charge separation due to induced internal electrical field.
33
34 1178 Nevertheless, ~~it is important that the~~ migration pathway of photocarriers and direction of
35
36 1179 built-in electric field must overlap each other in order to achieve accelerated charge
37
38 1180 separation which can be further improved by band bending through polarization.
- 39 1181 (4) For effective forward charge **transference** and utilization along with suppressed
40
41 1182 reassembly, integrated co-catalyst/semiconductor systems should be rationally designed.
42
43 1183 Of note, challenging deposition of ultrathin layer precisely on the semiconductor surface
44
45 1184 without obstruction in migration of photocarriers to co-catalyst can be prevailed partially
46
47 1185 using atomic layer deposition technique.
- 48 1186 (5) Deprived absorption of undeviating sun-light is another bottleneck along with scalability
49
50 1187 and operability of photocatalytic material for their long lifespans in forthcoming
51
52 1188 practical applications.
- 53
54 1189 (6) Higher practicability of a photocatalyst is associated with its separation efficiency,
55
56 1190 thereby, semiconductor materials should be anchored on functional polymeric inorganic
57
58 1191 membranes to achieve effectual separation efficacy.

1
2
3
4 1192 (7) Advanced characterization techniques should be implemented to understand interfacial
5
6 1193 activities of semiconductors to utilize their worth fully in photocatalytic activity.

7
8 1194 (8) More in-situ investigation techniques should be incorporated in order to examine the
9
10 1195 charge migration pathway and the underlying reaction mechanism.

11
12 1196 To trigger a plethora of attempts in the modification of g-C₃N₄ based Z-scheme photocatalysis,
13
14 1197 some other considerations should also be envisaged like; semiconductor material should have
15 1198 improved visible light response, relatively high VB edge to provide strong oxidation potential,
16
17 1199 high physicochemical endurance and surface contact should be compact. From future
18
19 1200 perspectives, the development of Z-scheme photocatalysis involving reductive photocatalysts ~~is~~
20
21 1201 ~~in-need-ofneeds~~ revision as; the mechanistic charge transfer pathway on the surface of
22
23 1202 semiconductors is still blurred and should be explored more. In ASS systems fermi level
24
25 1203 positions of solid-state electron mediator and semiconductor must be precisely concerned.
26 1204 Furthermore, modification in band edge positioning should be exploited in order to achieve
27
28 1205 superior redox abilities. Also, factors which influence the quantum efficiency of photocarriers
29
30 1206 should be evaluated. Only a few studies have reported in-situ characterisation techniques for
31
32 1207 clarity of charge carrier migration pathway *via* Z-scheme mode. More such techniques should be
33
34 1208 involved for scrutinising charge transfer pathways through Z-scheme mechanism.

35 1209 Considering our present level of knowledge and available technology, updating photocatalytic
36
37 1210 efficacy on industrial level utilizing narrow band-gap semiconductors which are lucrative and
38
39 1211 abundant still needs improvement. More development in the field of Z-scheme photocatalysis is
40
41 1212 peremptory, preferably in conjunction with innovative discoveries emanate from inclusive
42
43 1213 research areas. Thus, it is our genuine hope that putting more efforts on this research area will
44
45 1214 ~~definitely~~ accelerate its widespread applications.

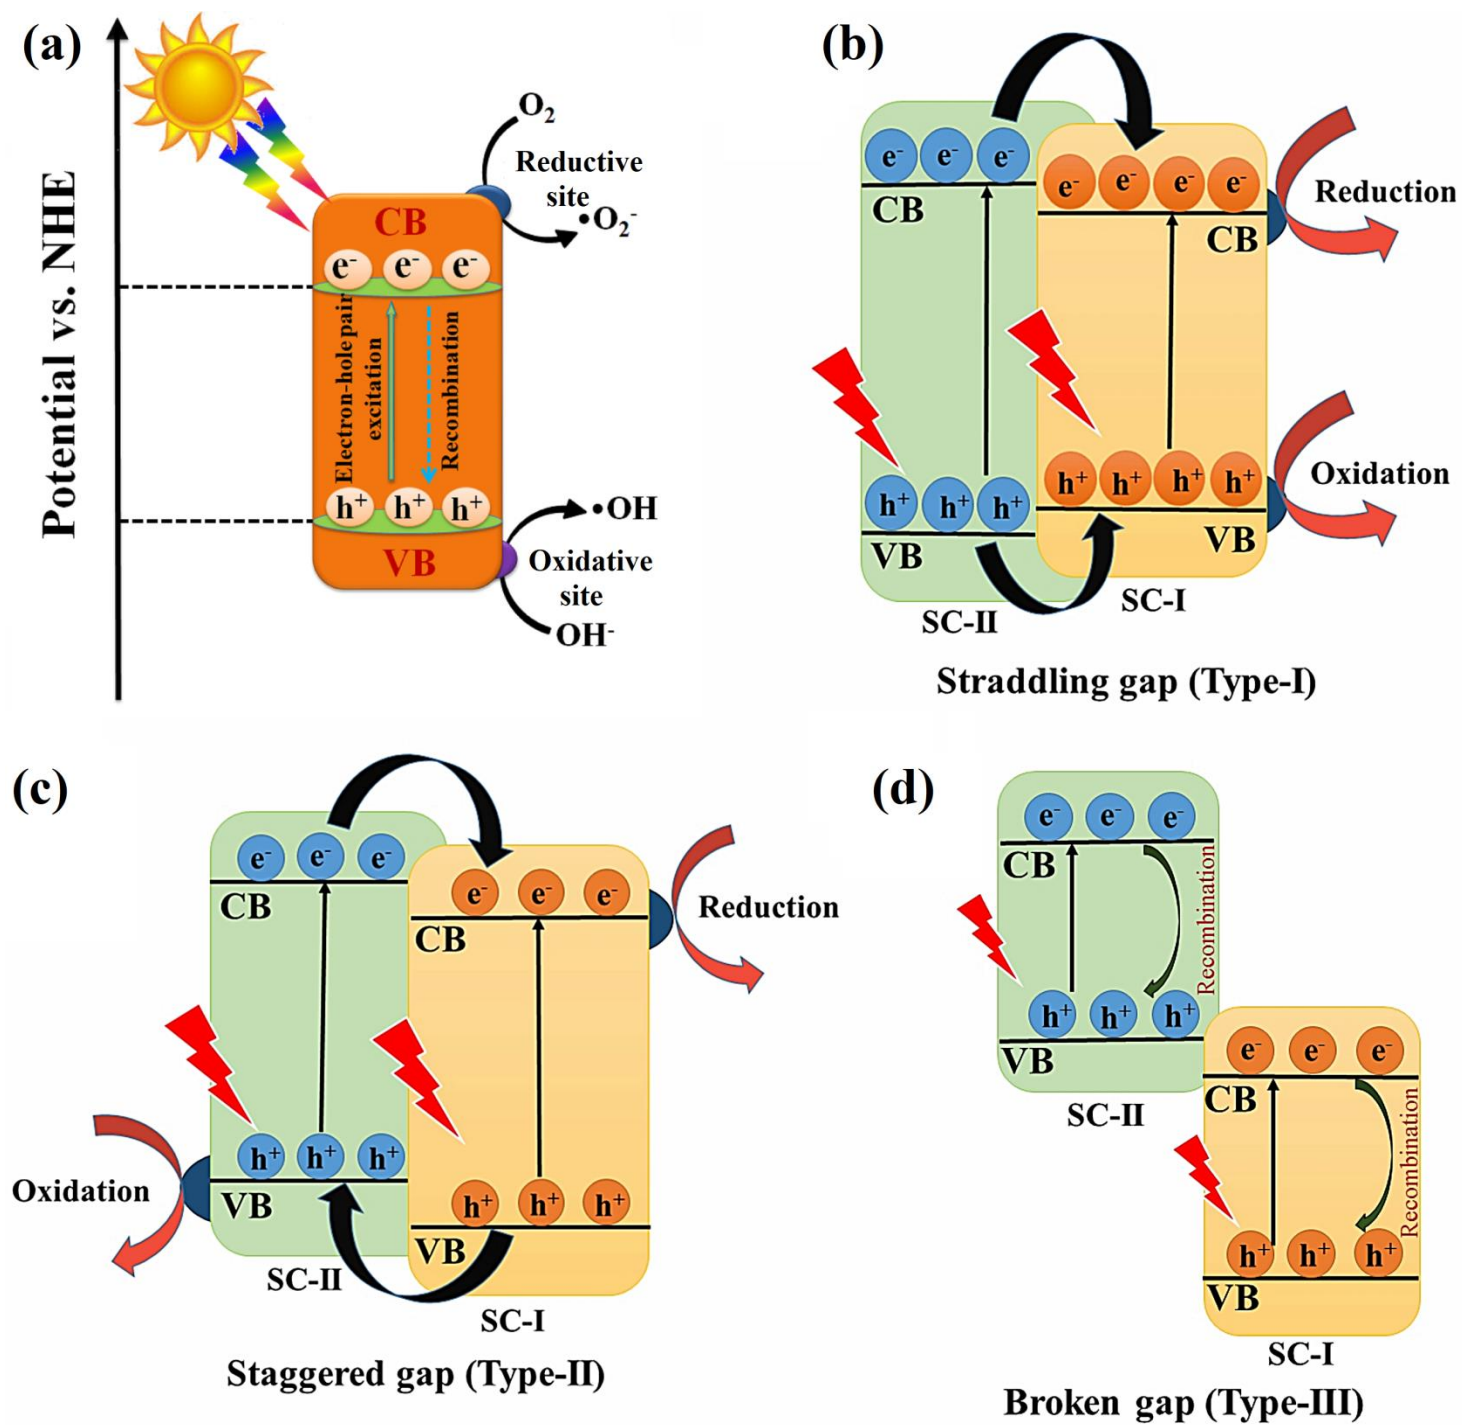

Fig. 1. (a) Schematic illustration of basic principle of photocatalysis. Traditional heterojunction photocatalysis illustrating double charge transfer mechanism in: (b) Type-I heterojunction, (c)

type-II heterojunction and (c) representation of broken band gap situation in type-III heterojunction, SC-I and SC-II represents semiconductor-I and semiconductor-II, respectively.

Fig. 2. Schematic illustration showing progression of Z-scheme photocatalysis from 1st generation to current 3rd generation. A/D, Acceptor/Donor pair.

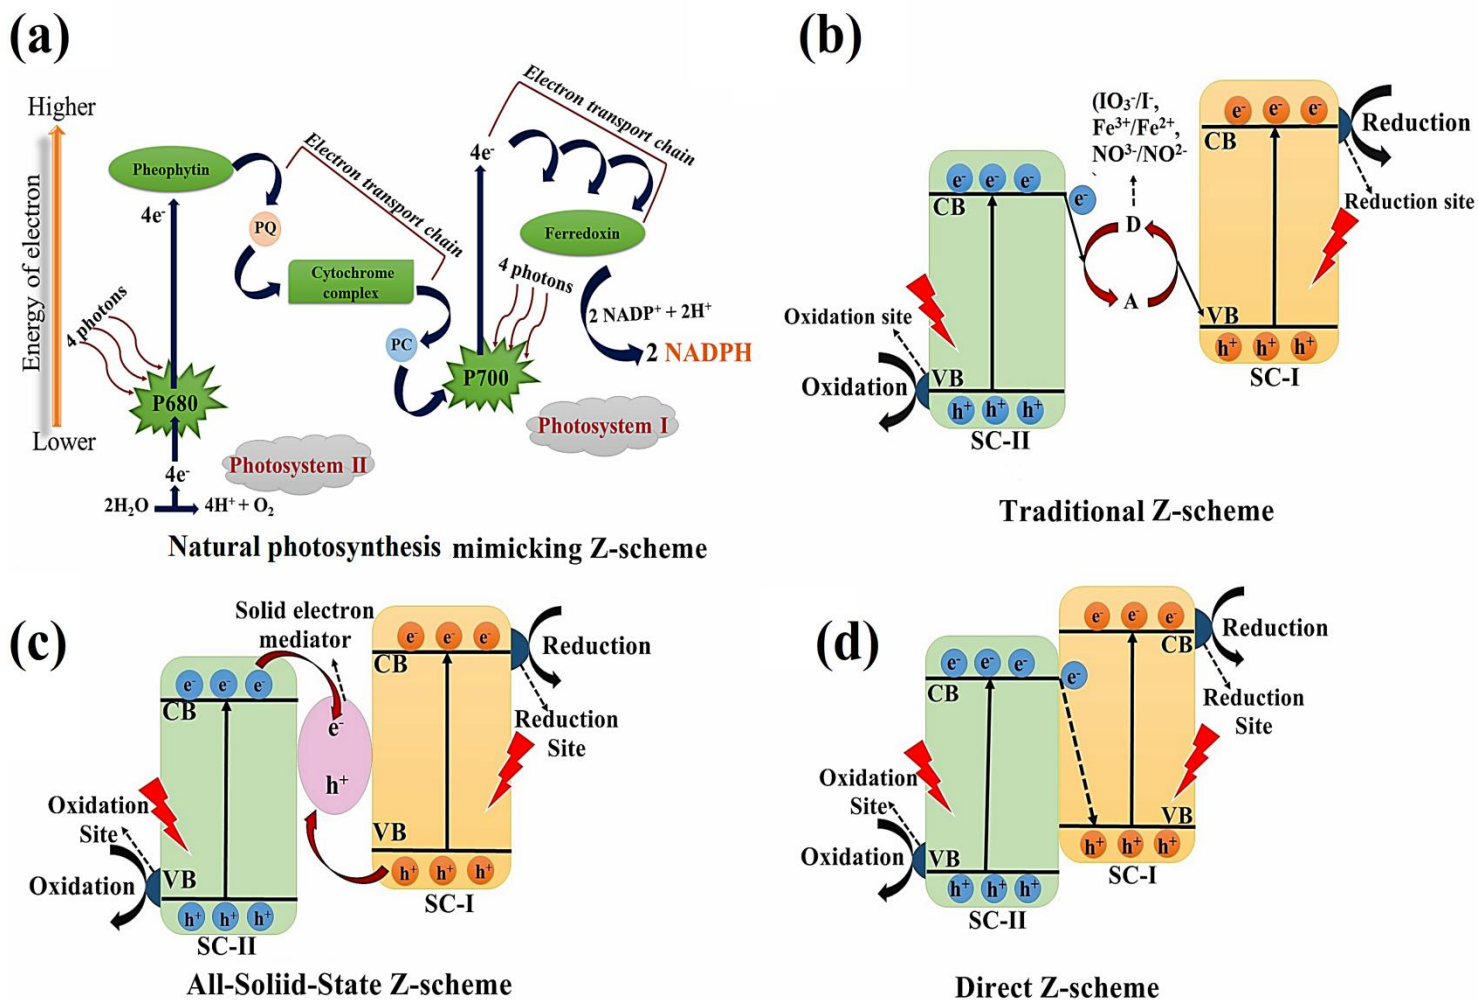

Fig. 3. (a) A schematic representation of double excitation process occurring on P680 and P700 through Natural Photosynthesis. (b) Charge transfer mechanism in traditional Z-scheme system with liquid-phase redox mediators, A and D represents Acceptor and donor pairs, respectively. (c) Charge transfer mechanism in all-solid-state Z-scheme system with solid state electron mediator and (d) Scheme of charge transfer and separation in direct Z-scheme system.

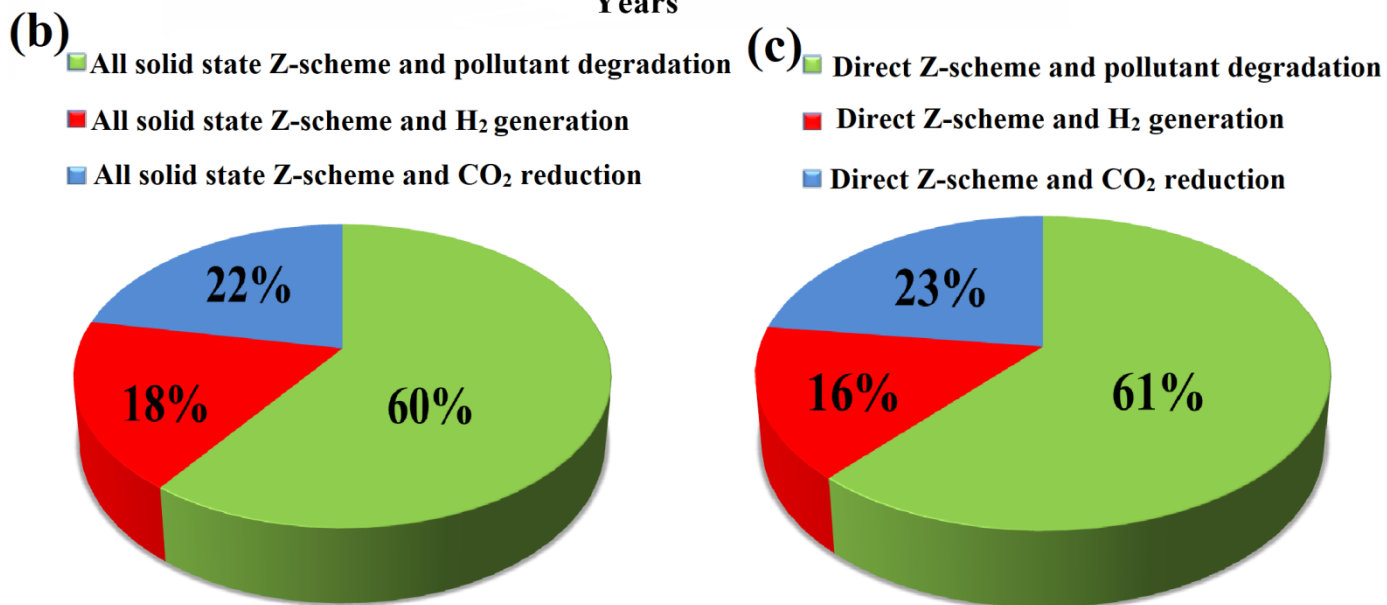

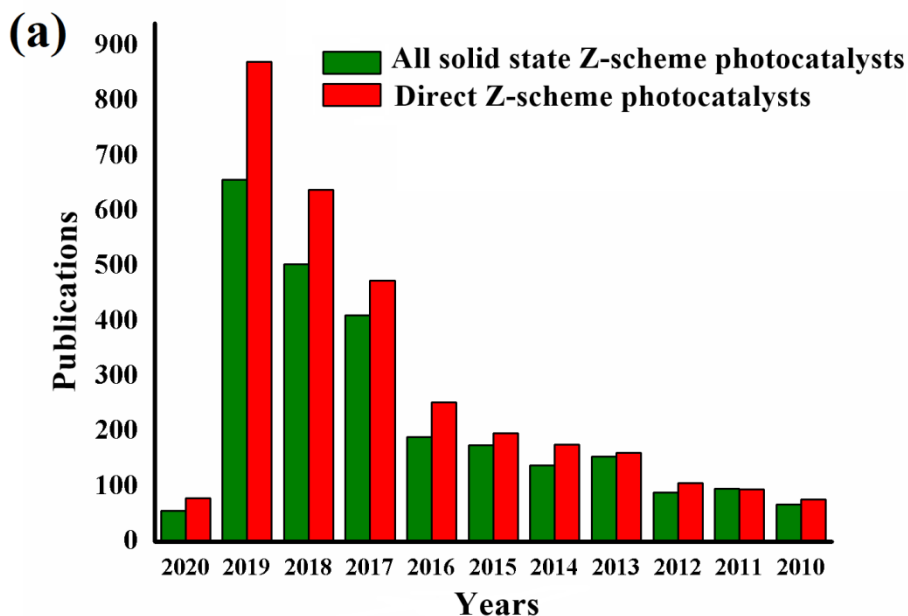

Fig. 4. (a) Total publications from 2009 to January, 2020 through Scopus Search Engine using keywords “All solid state Z-scheme Photocatalysts” and “Direct Z-Scheme Photocatalysts”. Environmental and energy applications representing the total percentage of; (b) All solid state Z-scheme photocatalysts and (b) Direct Z-scheme photocatalysts.

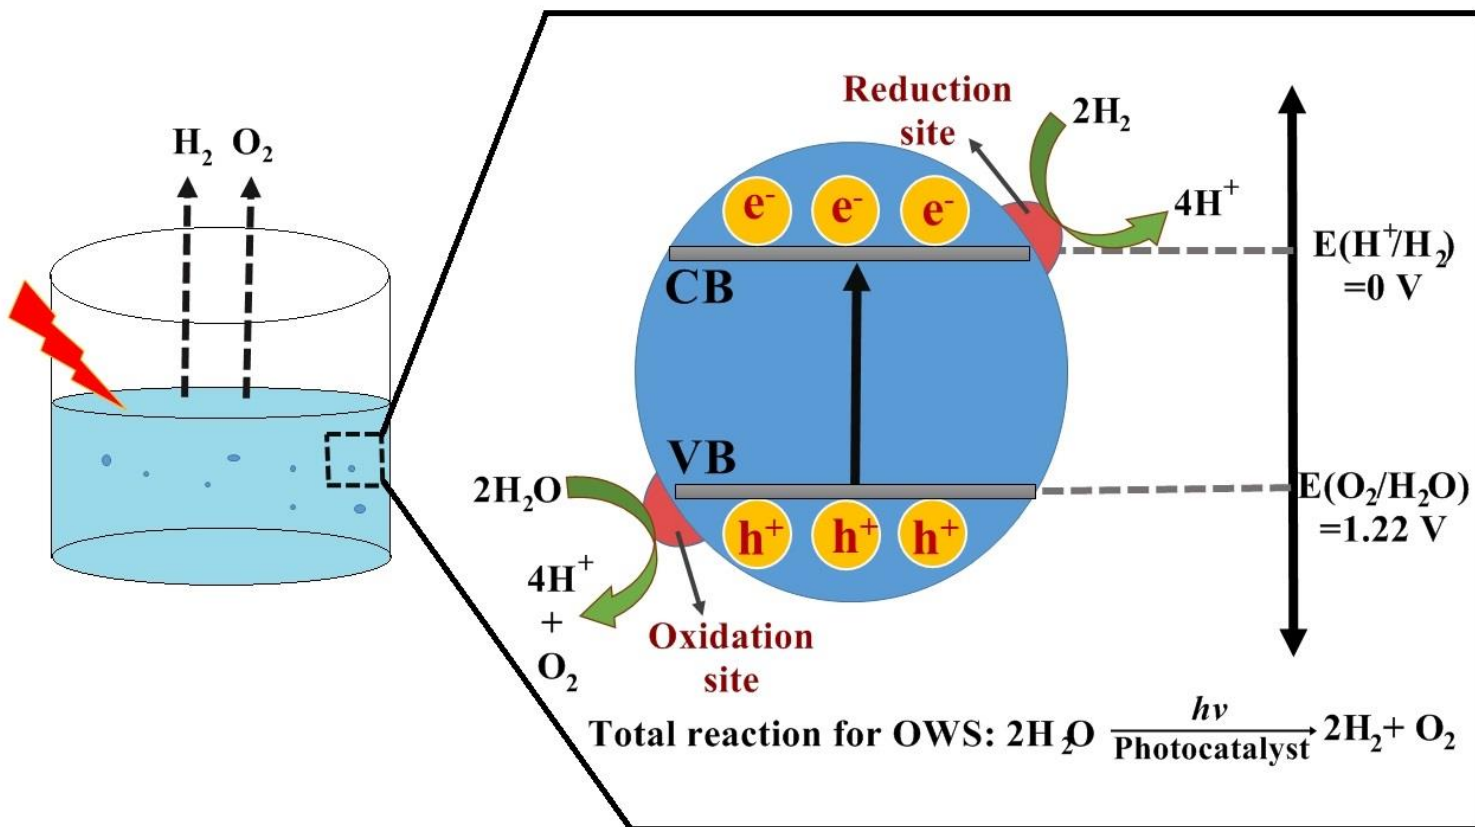

Fig. 5. Schematic illustration of visible light driven water splitting process carried on a single photocatalyst system.

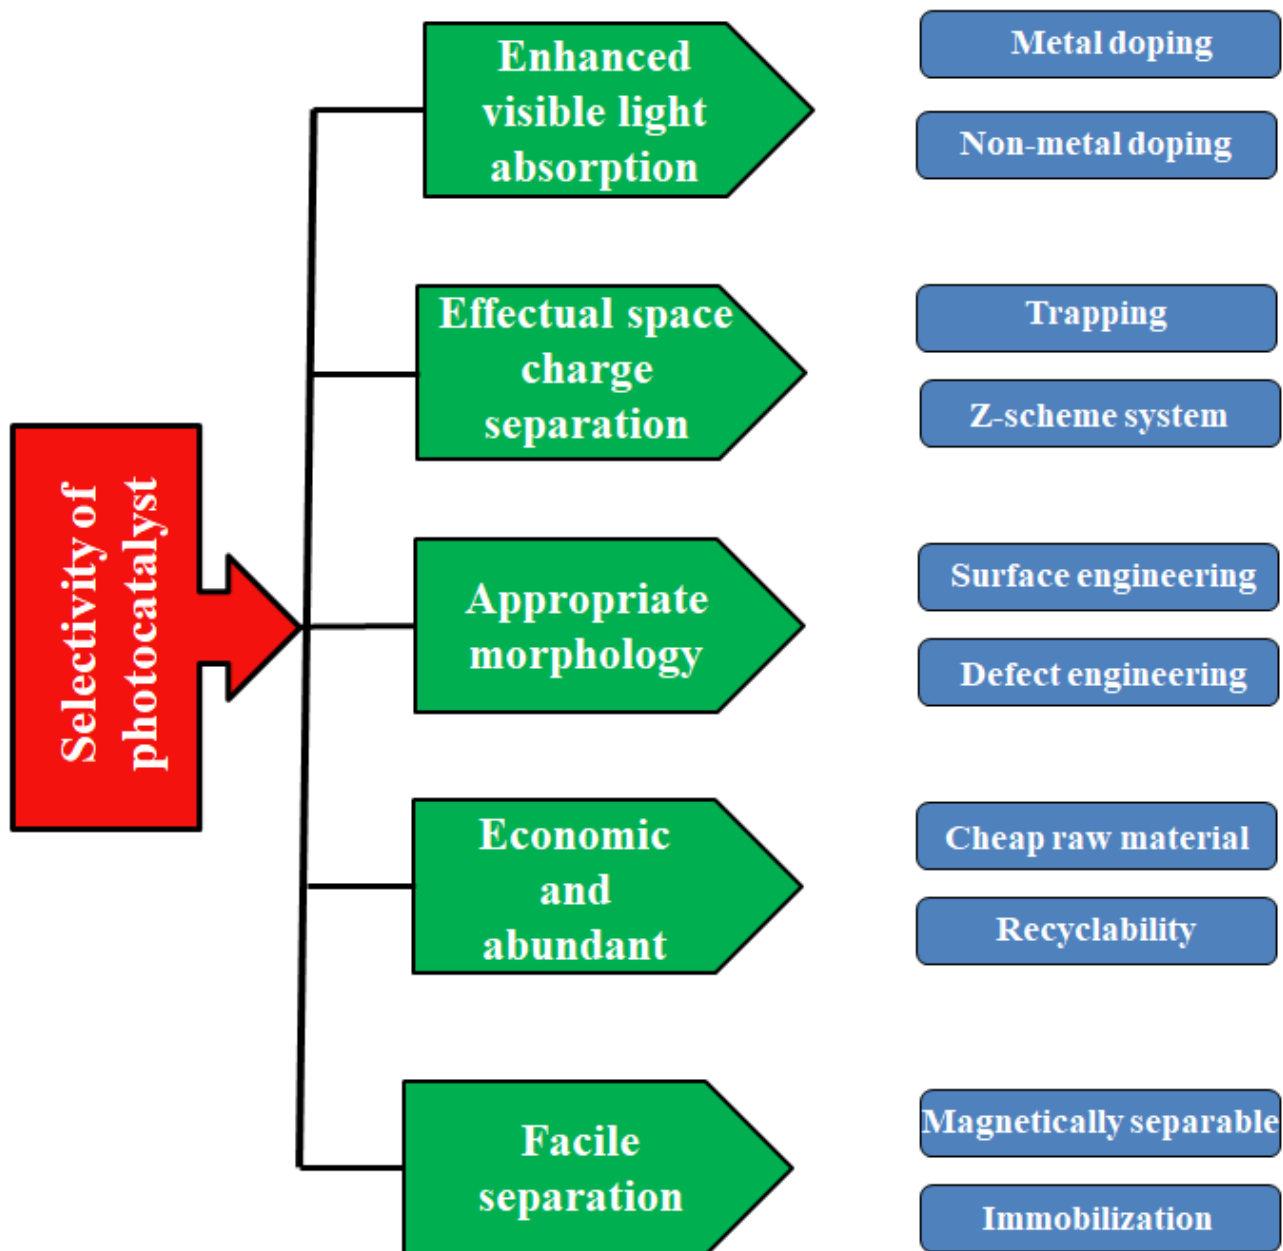

Fig. 6. Diagrammatic representation of basic aspects involved in selectivity of photocatalyst.

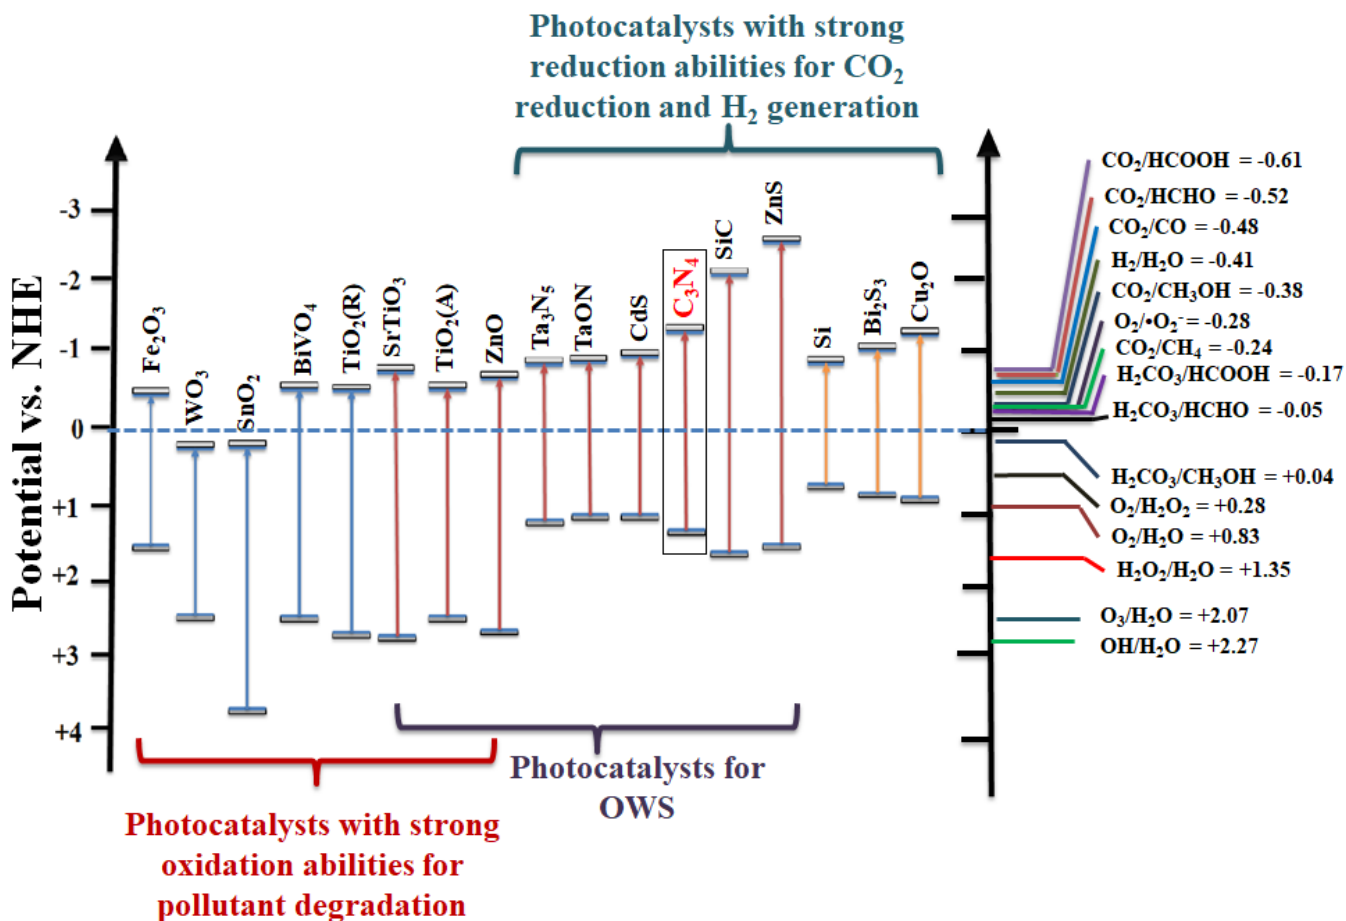

Fig. 7. Representation of redox potentials of various photocatalysts for their application in environmental and energy remediation.

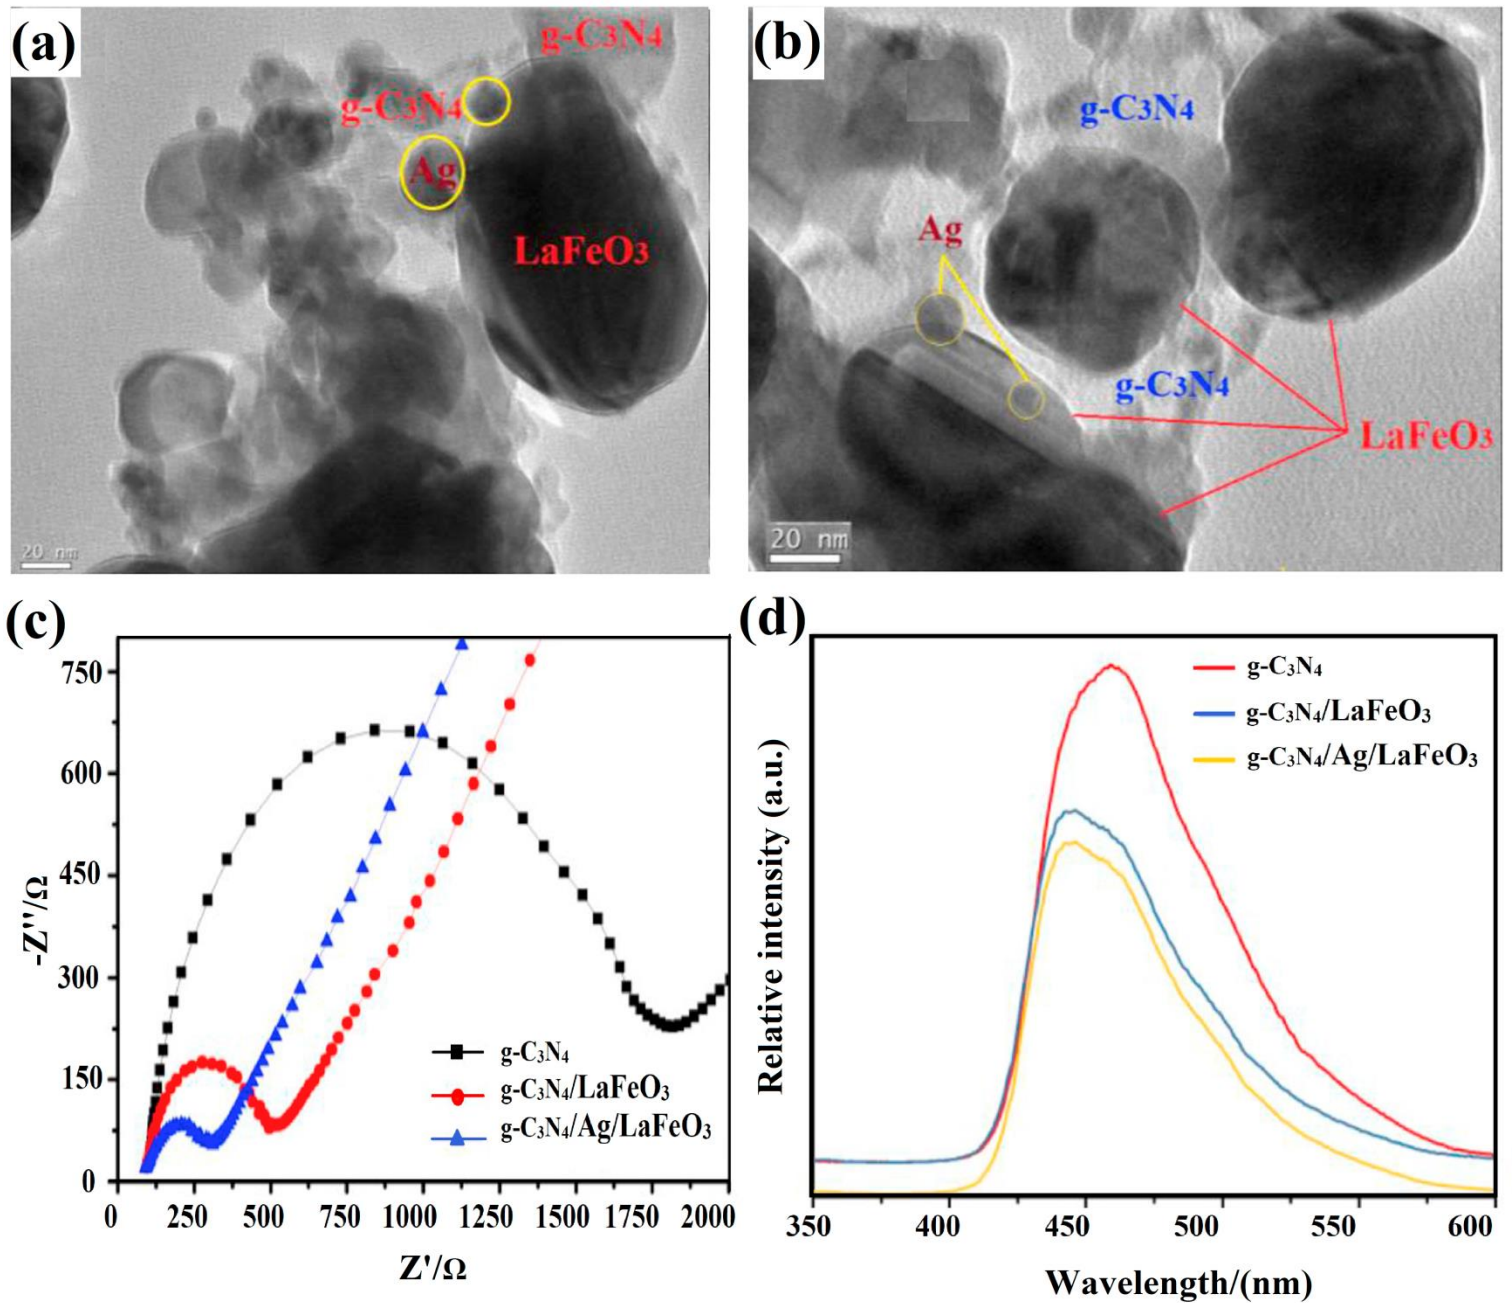

Fig. 8. Schematic illustration of: (a, b) TEM images of g-C₃N₄/Ag/LaFeO₃ nanohybrid, (c) EIS spectrum and (d) photoinduced fluorescence spectroscopic analysis of g-C₃N₄, g-C₃N₄/LaFeO₃

and g-C₃N₄/Ag/LaFeO₃ nanohybrid. Adapted from Elsevier under License No. 4891440827977) [127].

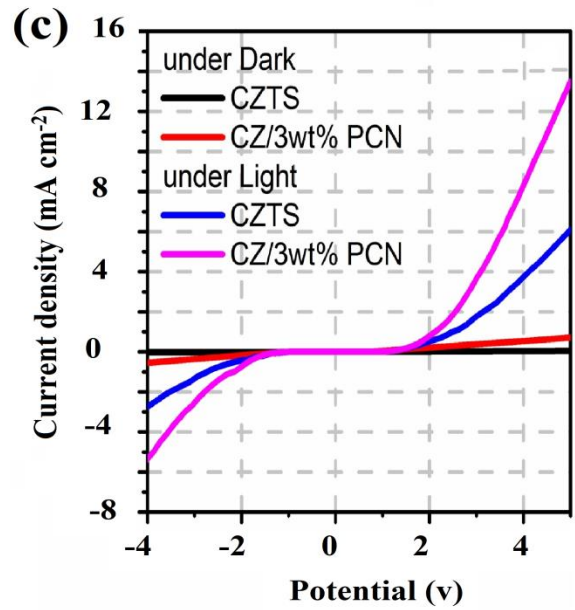

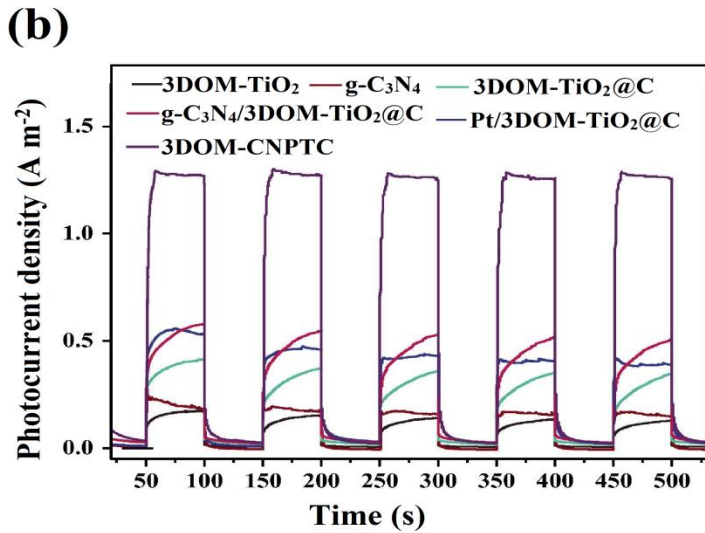

Fig. 9. Schematic illustration of: (a) mechanistic insight into the synthesis process of 3DOM-CNPTC photocatalyst, (b) Photocurrent responses of various samples, (c) LSV curves of various samples under dark and light illumination, adapted with permission from Elsevier (License no. 4891450608052) [128], and (d) distinct charge migration modes for photocatalytic CO₂ reduction in CZ/3 wt% PCN heterostructures, reproduced with permission from Elsevier (License no. 4891450418062) [129].

Fig. 10. (a) SEM image, (b) TEM image and (c) HR-TEM image of CN/C/ZIS nanocomposite. TG curves of the samples: (d) ZIS, CN/ZIS, C/ZIS and CN/C/ZIS; (e) CN and C/CN. (f) Raman spectra of CN/C/ZIS nanocomposite. CN represents g-C₃N₄. Reprinted with permission from RSC [133].

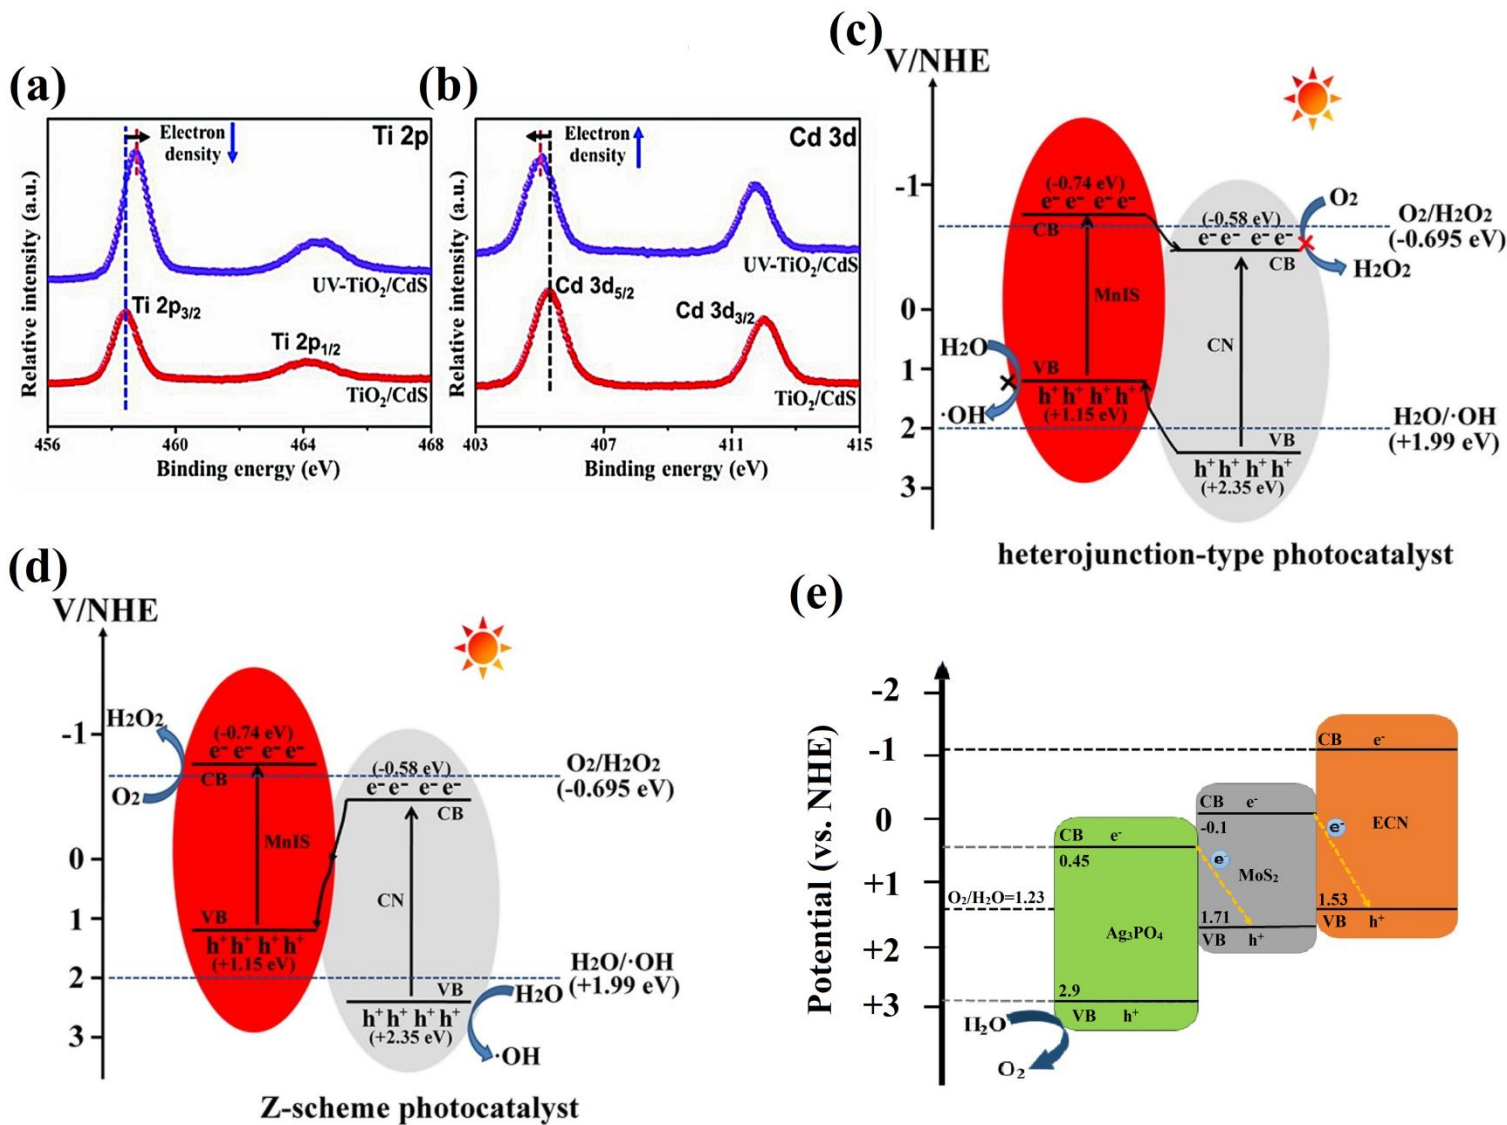

Fig. 11. Schematic illustrating the high-resolution XPS of: (a) Ti 2p and (b) Cd 3d in TiO₂/CdS nanocomposite, Reproduced with permission from Elsevier (License no. 4891850467496) [139] (c) Typical double charge transfer in MnIn₂S₄/g-C₃N₄ (MnIS/CN) heterojunction system, which do not form. (d) Direct Z-scheme MnIS/CN photocatalyst for H₂ production, reprinted with permission from Elsevier (Licence no. 4566470506559) [140]. (e) Ag₃PO₄/MoS₂/g-C₃N₄ ternary Z- scheme photocatalyst for O₂ evolution from overall water splitting, ECN represents modified g-C₃N₄ nanosheets.

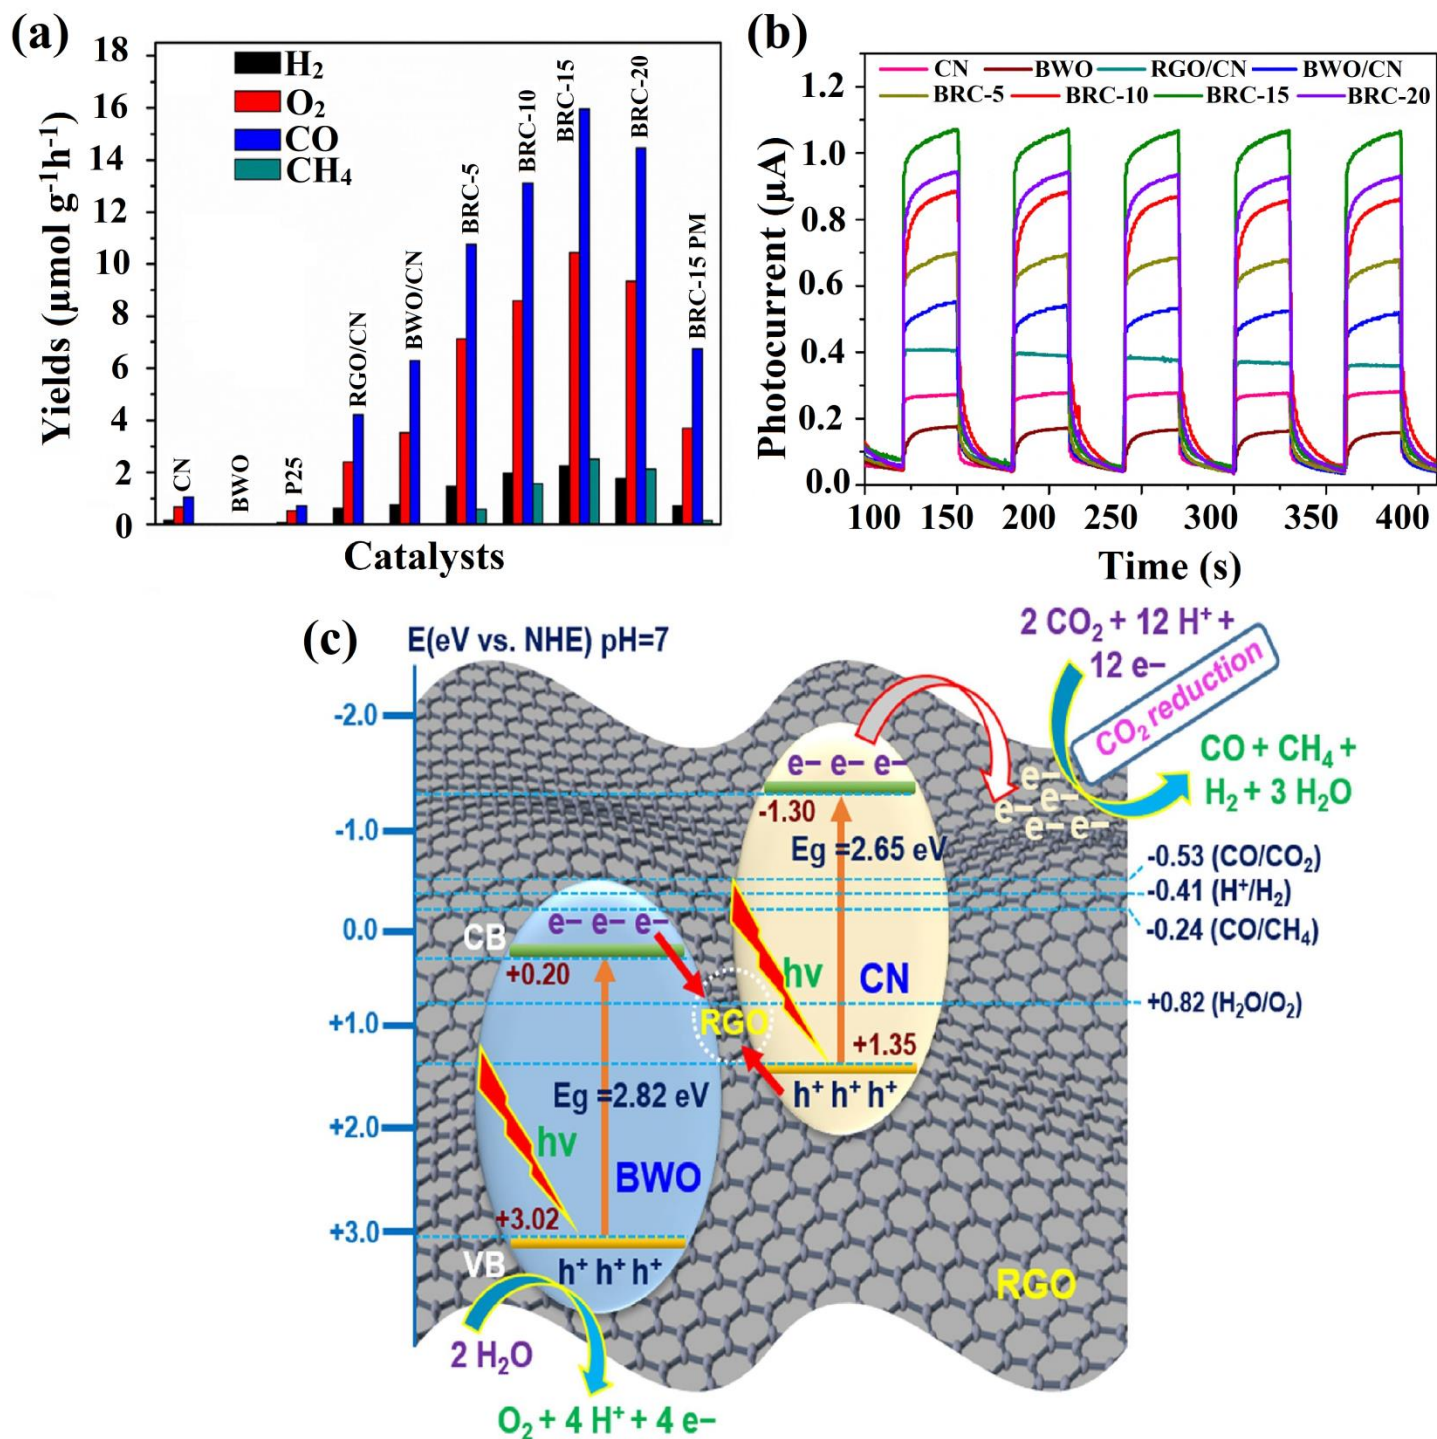

Fig. 12. (a) Comparison of the photoassisted CO , CH_4 , H_2 , and O_2 production rates of all the synthesized photocatalysts under visible light illumination for 5 h. (b) Photocurrent responses of CN, BWO, BWO/CN, RGO/CN, and BWO/RGO/CN photocatalysts. (c) Schematic illustration of the proposed mechanism for CO_2 photoreduction in the BWO/RGO/CN nanohybrid. Reproduced with permission from Elsevier (License No. 4700150753077) [150].

Fig. 13. Synthesis route along with spatial charge separation of a direct Z-scheme AgCl@g-C₃N₄ photocatalyst for CO₂ reduction into CH₄, CH₃COOH and C₂H₅OH, reproduced with permission from Elsevier (Licence no. 4566480298200) [151].

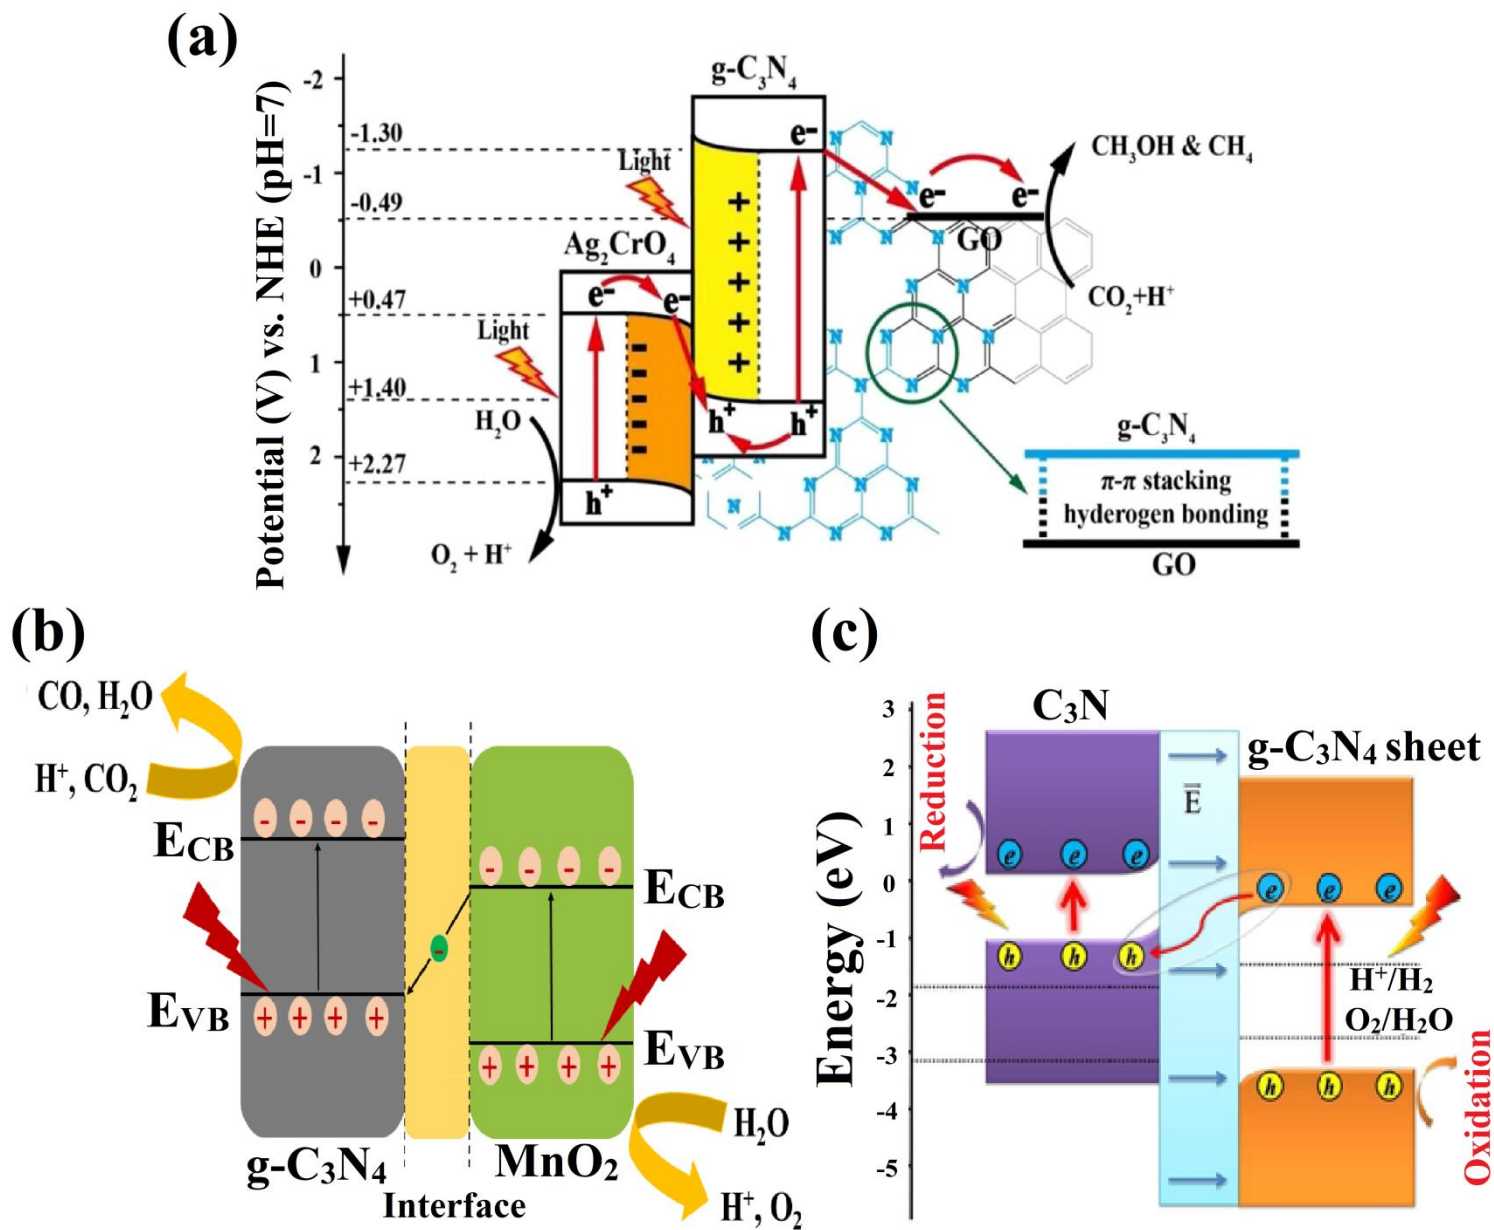

Fig. 14. Schematic representation of: (a) A novel ternary $\text{Ag}_2\text{CrO}_4/\text{g-C}_3\text{N}_4/\text{GO}$ Z-scheme photocatalyst for CO_2 reduction into CH_3OH and CH_4 , reproduced with permission from Elsevier (Licence no. 4566481143580) [152]. (b) Charge carrier migration in $\text{g-C}_3\text{N}_4/\text{MnO}_2$ photocatalyst through interfacial ohmic-contact, reprinted with permission from ACS [154], (c) Charge transfer pathway in metal free $\text{C}_3\text{N}/\text{g-C}_3\text{N}_4$ photocatalyst for overall water splitting [164].

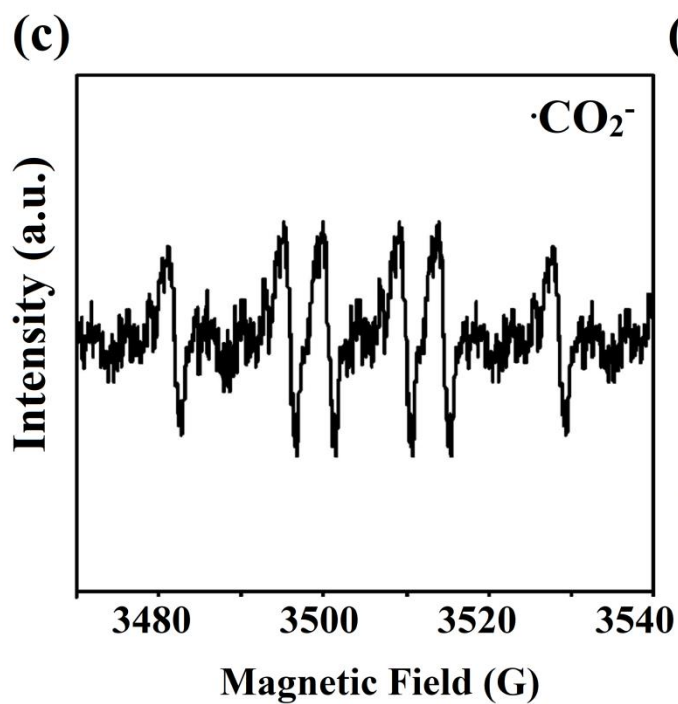

Fig. 15. Schematic representation of: (a) Au mediated all-solid-state Z-scheme photocatalyst for H₂ production, reprinted with permission from Wiley (license no. 4566490300093) [175], (b) 3,4-dihydroxybenzaldehyde (DBD) as an electron mediator in Ga₂O₃/g-C₃N₄ for visible light assisted photocatalytic N₂ fixation. (c) DMPO spin-trapping ESR spectra recorded for •CO₂⁻ in 0.2 mol L⁻¹ methanol aqueous solution. (d) Photocurrent transient responses of 2.4%Ga₂O₃/g-C₃N₄ and 2.4%Ga₂O₃-DBD/g-C₃N₄, reproduced with permission from Elsevier (Licence no. 4703761323347) [179],

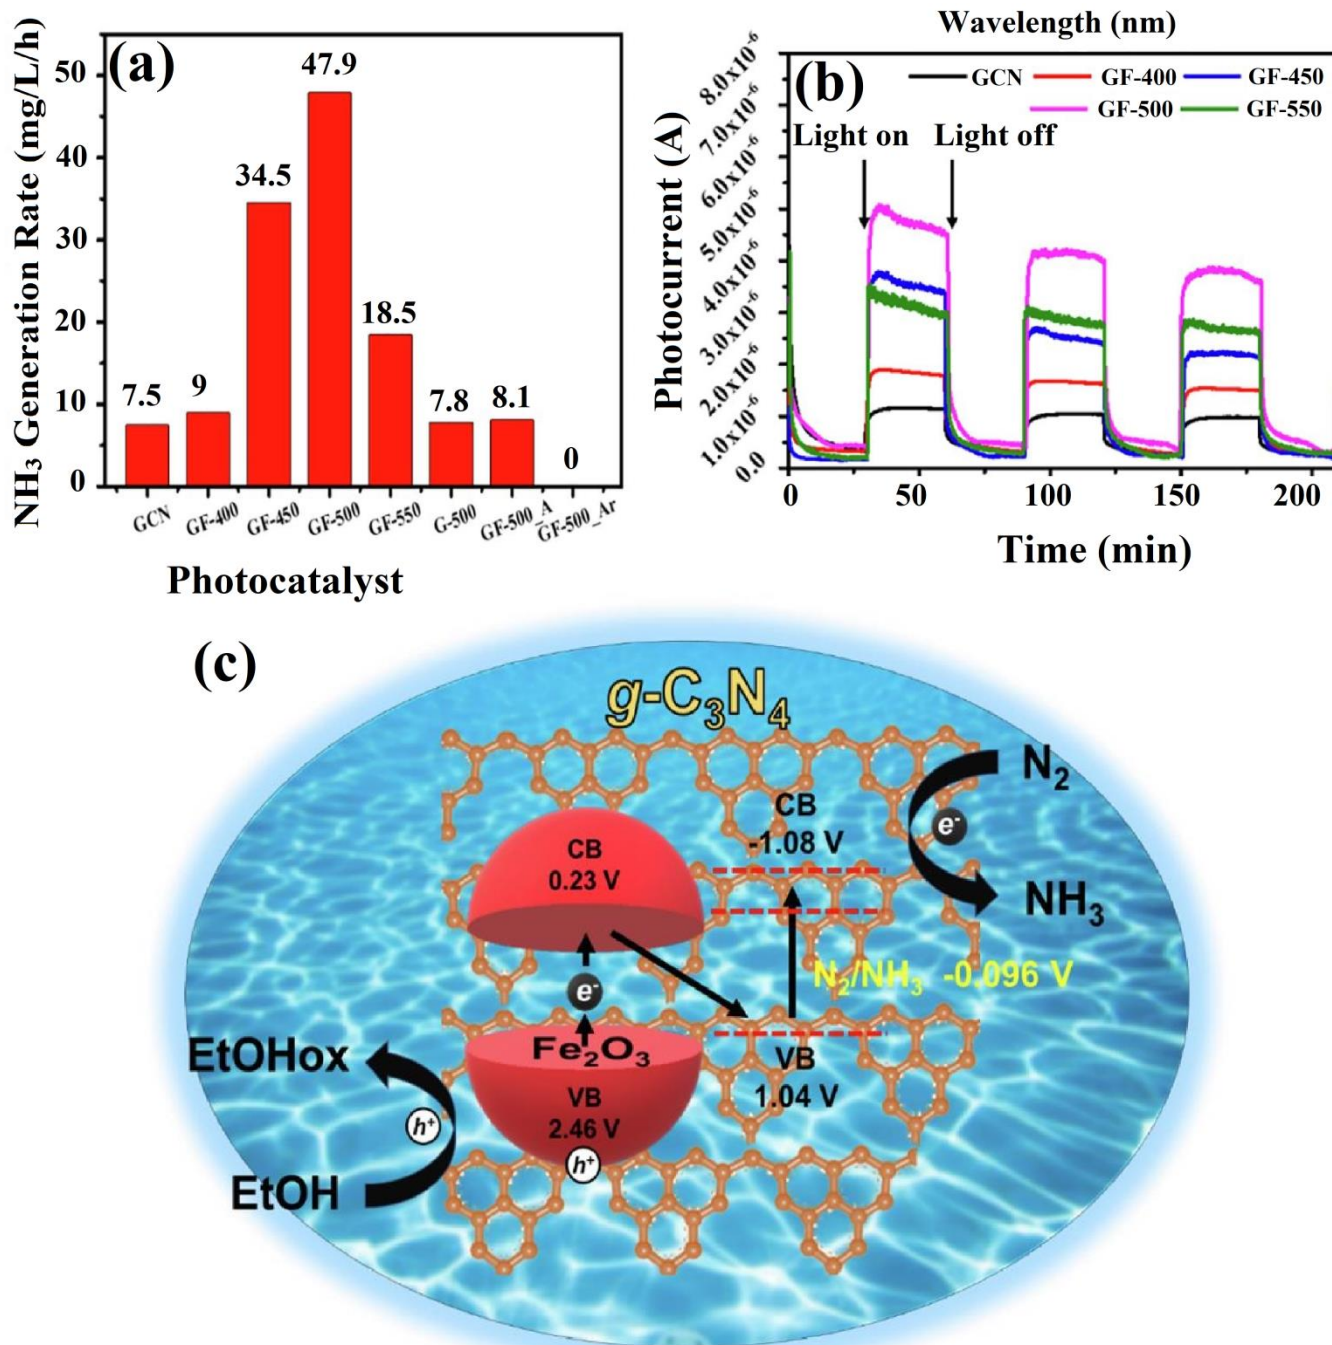

Fig. 16. (a) Rates of NH₃ generation of GCN, GF-400, GF-450, GF-500, GF-550, G-500, and HCl solution treated GF-500 (GF-500_A) as well as GF-500 in a control experiment with Ar. (b) Photocurrent generation analysis of different composites. (c) Schematic representation of photocatalytic N₂ reduction over Fe₂O₃ loaded g-C₃N₄. Reprinted with permission from Elsevier (License No. 4703770265600) [180].

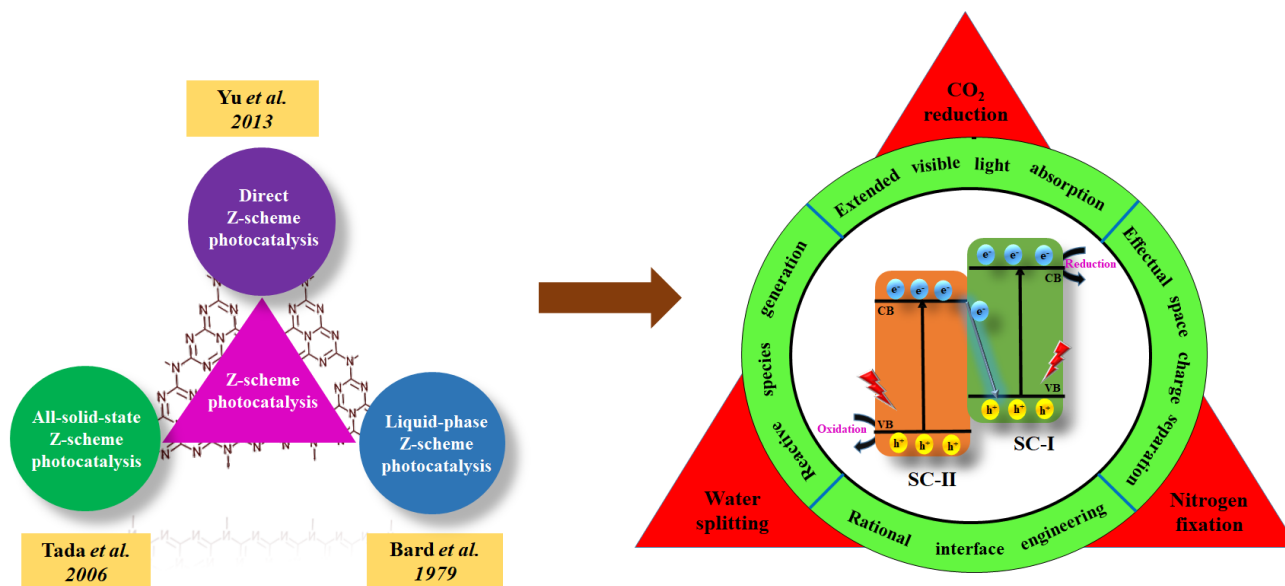

Fig. 16. Conclusive overview of $g\text{-C}_3\text{N}_4$ based Z-scheme photocatalytic system.

Table 1: Summary of ASS Z-scheme photocatalytic systems for H₂ production and CO₂ reduction.

<i>Photocatalyst</i>	<i>Solid-state electron mediator</i>	<i>Synthesis route</i>	<i>Active species</i>	<i>Application</i>	<i>Enhanced photocatalytic efficiency (%) / Activity</i>	<i>Ref.</i>
<i>Zn_{0.5}Cd_{0.5}S-MWCNT-TiO₂</i>	<i>multi-walled carbon nanotubes (MWCNTs)</i>	<i>coating and hydrothermal route</i>	<i>-</i>	<i>H₂ production</i>	<i>Zn_{0.5}Cd_{0.5}S-MWCNT-TiO₂: 21.9 μmol h⁻¹</i>	<i>[186]</i>

$WO_3/g-C_3N_4/Ni(OH)_x$	Calcination and photodeposition	$\bullet O_2^-$ and $\bullet OH$	H_2 production	20 wt. % $WO_3/g-C_3N_4/4.8 \text{ wt. } \%$ $Ni(OH)_x$: 576 $\mu\text{mol h}^{-1} g^{-1}$ (10.8 \times $\sim 20 \text{ wt. } \%$ $WO_3/g-C_3N_4$)	[228]
$NiCo_2O_4/g-C_3N_4$	Calcination and hydrothermal method	h^+	H_2 production	17.5 wt % $NiCo_2O_4/g-C_3N_4$: 5480 $\mu\text{mol h}^{-1} g^{-1}$	[229]
$Mo-Mo_2C/g-C_3N_4$	Ultrasound assisted deposition method	--	H_2 production	2.0 wt % $Mo-Mo_2C/g-C_3N_4$: 219.7 $\mu\text{mol h}^{-1} g^{-1}$ (440 \times $\sim g-C_3N_4$, 3.6 \times $\sim 2.0 \text{ wt. } \%$ $Mo_2C/g-C_3N_4$)	[230]
$KTa_{0.75}Nb_{0.25} (KTN)/g-C_3N_4$	Microwave heating	--	H_2 production	(KTN)/ $g-C_3N_4$: 1673 $\mu\text{mol h}^{-1} g^{-1}$ (2.5 \times $\sim KTN$) (2.4 \times $\sim g-C_3N_4$)	[231]
2D/2D $WO_3/g-C_3N_4$	Ultrasonication and two-step thermal-etching	$\bullet O_2^-$	H_2 production	15 % $WO_3/g-C_3N_4$: 982 $\mu\text{mol h}^{-1} g^{-1}$ (1.7 \times $\sim g-C_3N_4$)	[232]
$g-C_3N_4-CoNiSe$	Calcination under N_2 atmosphere	e^-	H_2 production	$CN-CoNiSe = 87.4 \times \sim g-C_3N_4$	[233]

$WO_3/g-C_3N_4$	Pyrolysis	--	H_2 production	9 % $WO_3/g-C_3N_4$: 11,000 $\mu\text{mol g}^{-1}$	[234]
2D $SnS_2/g-C_3N_4$	Microwave assisted	e^-	H_2 production	5wt % $SnS_2/g-C_3N_4$: 972.6 $\mu\text{mol h}^{-1} \text{g}^{-1}$	[235]
Metakaolin/ $g-C_3N_4$ (MK/CN)	One-pot heating treatment	e^-	H_2 production	MK/CN-70.4 % : 288 $\mu\text{mol h}^{-1} \text{g}^{-1}$ (1.5 \times $g-C_3N_4$)	[236]
$g-C_3N_4-Ni_2P-MoS_2$	In-situ phosphorization reaction	--	H_2 production	$g-C_3N_4$ -1 % Ni_2P -1.5 % MoS_2 : 532.41 $\mu\text{mol h}^{-1} \text{g}^{-1}$ (2.47 \times $g-C_3N_4$ -1.5 % MoS_2) (5.15 \times $g-C_3N_4$ -1 % Ni_2P)	[237]
Cu-loaded $g-C_3N_4/1D$ hydrogenated black TiO_2 nanofiber (CuCNBTNF)	Electrospinning process followed by thermal treatment	$\bullet O_2^-$	H_2 production	CuCNBTNF-5: 3.3 $\text{mmol h}^{-1} \text{g}^{-1}$	[238]
SnO_2 -coupled boron and phosphorus co-doped $g-C_3N_4(SO/B-P-CN)$	Calcination	$\bullet OH$	CO_2 reduction	6SO/0.12B-0.2P-CN: 49 $\mu\text{mol h}^{-1} \text{g}^{-1}$ (9 \times $g-C_3N_4$)	[239]
$g-C_3N_4/ZnO$	Hydrothermal-calcination process	$\bullet OH$ and e^-	CO_2 reduction	CH_3OH production: $g-C_3N_4/ZnO$: 1.32 $\mu\text{mol h}^{-1} \text{g}^{-1}$, (2.1 \times ZnO), (4.1 \times $\mu\text{mol h}^{-1} \text{g}^{-1}$)	[240]
Porous $g-C_3N_4/Sn_2S_3^-$ diethylenetriamine (Pg- $C_3N_4/Sn_2S_3^-$ -DETA)	Hydrothermal process	e^- and h^+	CO_2 reduction	5 % Pg- $C_3N_4/Sn_2S_3^-$ -DETA : CH_4 : 4.93 $\mu\text{mol h}^{-1} \text{g}^{-1}$ CH_3OH : 1.49 $\mu\text{mol h}^{-1} \text{g}^{-1}$	[241]
$g-C_3N_4/ZIF-67$	Aging process	e^- and h^+	CO_2 reduction	C_2H_5OH production: $g-C_3N_4/ZIF-67$: 325.5 $\mu\text{mol. gcat}^{-1}$ (2 \times $g-C_3N_4$)	[242]
$g-C_3N_4/SnS_2$	Hydrothermal process	e^- and h^+	CO_2 reduction	CH_3OH production: $g-C_3N_4/SnS_2$: 2.3 $\mu\text{mol g}^{-1}$ CH_4 production: $g-C_3N_4/SnS_2$: 0.64 $\mu\text{mol g}^{-1}$	[243]
$Cu_2V_2O_7/g-C_3N_4$	Hydrothermal and calcination	e^- and h^+	CO_2 reduction	CH_4 production: 50 $Cu_2V_2O_7/50 g-C_3N_4$: 305 $\mu\text{mol. g}^{-1} \text{cat. h}^{-1}$ CO production: 50 $Cu_2V_2O_7/50 g-C_3N_4$: 166 $\mu\text{mol. g}^{-1} \text{cat. h}^{-1}$ O_2 production: 50 $Cu_2V_2O_7/50 g-C_3N_4$: 706 $\mu\text{mol. g}^{-1} \text{cat. h}^{-1}$	[58]
$CdS/g-C_3N_4$	Polycondensation and hydrothermal method	e^- and h^+	CO_2 reduction	Methyl formate production: 1 % $CdS/2$ % $g-C_3N_4$: 1352.07 $\mu\text{mol. g}^{-1} \text{cat. h}^{-1}$	[244]
