ABSTRACT

Introduction: The legalization of cannabis across Canada in October 2018 introduced issues including regulation at different levels, public and individual education, and discussions about cannabis product safety. We aimed to discuss ineffective and effective cannabis use policy on campuses and associated public areas, given the known short-term and long-term effects pertaining to its neurologic, pulmonary, and purported medicinal effects. Cannabis interferes with many of the body's basic and executive (higher-level) functions. It is also associated with long-term harmful effects when chronically used. The purpose of this paper is to review and further discuss the responsibility local governments and educational institutions have for creating policies and regulations around cannabis use, particularly within post-secondary institutions, and for implementing educational strategies to promote public knowledge of cannabis.

Methods: Peer-reviewed articles published in the last 10 years were searched for through the MEDLINE database. In addition, national and local health-related websites discussing cannabis policies were reviewed and collated. Expert opinions were also sought out to provide further information and resources.

Results: 31 peer-reviewed articles and 12 professional websites were retrieved and reviewed. Correspondences with individual experts aware of and involved with campus cannabis policies also provided relevant resources and data used in this document.

Conclusion: Smoke-free campus policies create the best health outcomes for the campus population. As well, creating effective and properly regulated policies and prioritizing public education is pertinent especially on universities where the population demographic is relatively young.

Introduction

The October 2018 legalization of cannabis in Canada has brought about a major increase in social acceptance of its use, particularly amongst Canadian youth and young adults.¹ Although major decisions are made at the federal level, each province, territory, and municipality is responsible for creating subsequent policies within their jurisdiction in the post-legalization context.¹ Educational institutions in Canada, including post-secondary institutions, need special attention given the higher use of cannabis among the age demographics (18-24 years old) primarily represented in these settings. Additionally, this relatively young group has the potential for greater long-term harm related to cannabis use. Cannabis can be consumed in various forms including “dry weed”, bong, edibles, and vaporizers – all of which use various chemicals found in the cannabis plant.^{2,3} The use of this drug, particularly when inhaled, has many acute and long-term detrimental effects. Action of local governments and educational institutions is needed, with the aim of educating the public and creating policies to protect and promote the health of all individuals. Through assessing effectiveness of policies and educational initiatives, this paper will discuss possible solutions to creating effective policies pertaining especially to regulation of recreational cannabis use on university campuses.

There appears to be an increase of cannabis use in Canada, with the past 16 years showing a slowly increasing trend.⁴⁻⁸ The rate of cannabis use recorded by annual Statistics Canada surveys from 2004-2017 showed a 60% increase in Canadian use overall.⁴ This increasing trend seems to still be present with recent Statistics Canada data from 2018 and 2019 showing a slight increase in national and Albertan percent of cannabis use post-legalization.⁹ Changes like this usually do not reach their full effect for a few years, suggesting the full outcome of this legalization remains currently unknown.^{10,11} One study supported this idea by finding a significant increase in cannabis use

only occurred a few years after implementation of more permissive retail restrictions.¹¹ This was due to the time needed for cannabis retailers to set up and create easier access to the drug.¹¹

Cannabis is used for multiple medicinal purposes; however, it also has many detrimental effects that should not be ignored.¹²⁻¹⁴ With its legalization, it is paramount that potential users are provided accurate information regarding both its beneficial and harmful effects. These educational measures must be prioritized by government and other policy makers in Canada and also by educational institutions. Currently, limited studies are available on the human health effects of cannabis, especially pertaining to causation - with existing research being largely observational and controversial.^{12,15,16} As well, a risk of bias and variability in populations and other parameters also may influence the variable results. Prospective clinical trials are needed to establish causation relationships between cannabis and human health, as opposed to retrospective studies that can only determine associations. Legalization and increased accessibility of cannabis will hopefully result in increased research on this topic, especially with increases in research funding and tax revenue. As well, being the first G7 country to legalize cannabis, better research can be conducted on national cannabis legalization to help direct policy-making.¹ Although certain American states have legalized recreational cannabis, the lack of a uniform national policy, the relatively early stages of legalization, and the inconclusiveness of the overall effects on population cannabis use makes it harder to use this data to predict possible long-term effects of Canadian legalization.¹⁷ Presently, legalization may mislead individuals, including young adults, toward safer perceptions of cannabis use and consequences, thereby resulting in a more carefree attitude towards it.

Methods

A comprehensive MEDLINE search was conducted for peer-reviewed articles focusing on the terms 'cannabis', 'cannabis AND policy', 'cannabis AND legalization', and 'drugs AND education' over the past decade (January 1, 2010 - April 31, 2020). Search results were further limited to humans and core clinical journals. Reference lists from retrieved literature were also reviewed to find other potential resources. Published literature pertaining to cannabis' medical use, acute effects, and long-term effects were selected as well as literature discussing policymaking and educational strategies and problems. Current literature, especially pertaining to prevalence rates and cannabis effects, were prioritized in order to get the most up to date information. Peer-reviewed papers discussing North American policies (Canada and the United States) were prioritized. Papers repeating information already provided by multiple other papers were excluded unless they provided additional information. Articles retrieved that did not relate to or were off topic were also excluded. This was done in conjunction with a review of online government, non-profit health organizations, and post-secondary university websites discussing cannabis poli-

cies, health policies, or campus health promotion. Correspondence and meetings were conducted with local experts on policies, cannabis or other substances, and public health. (Figure 1)

Results

A total of 31 articles and 12 authoritative health-related websites were retrieved and reviewed (Table 1). Discussions with professionals led to obtaining further relevant websites and resources including the 4 National College Health Assessment (NCHA) surveys (2011, 2013, 2016, 2019). Information was combined and summarized below.

Reviewed articles showed the alleged medicinal benefits of cannabis span the treatment of chronic neuropathic pain, vomiting, nausea, and management of cancer therapy side effects.¹⁵ These treatments utilize the various effects cannabis has on an individual's brain through chemicals that directly target the nervous system. The primary and most potent psychoactive component (chemical) in cannabis is tetrahydrocannabinol (THC), which may be modified or removed from medicinal cannabis products to eliminate some of its unwanted psychoactive effects.^{14,16,18} THC, mainly used recreationally, activates cannabinoid receptors in the nervous sys-

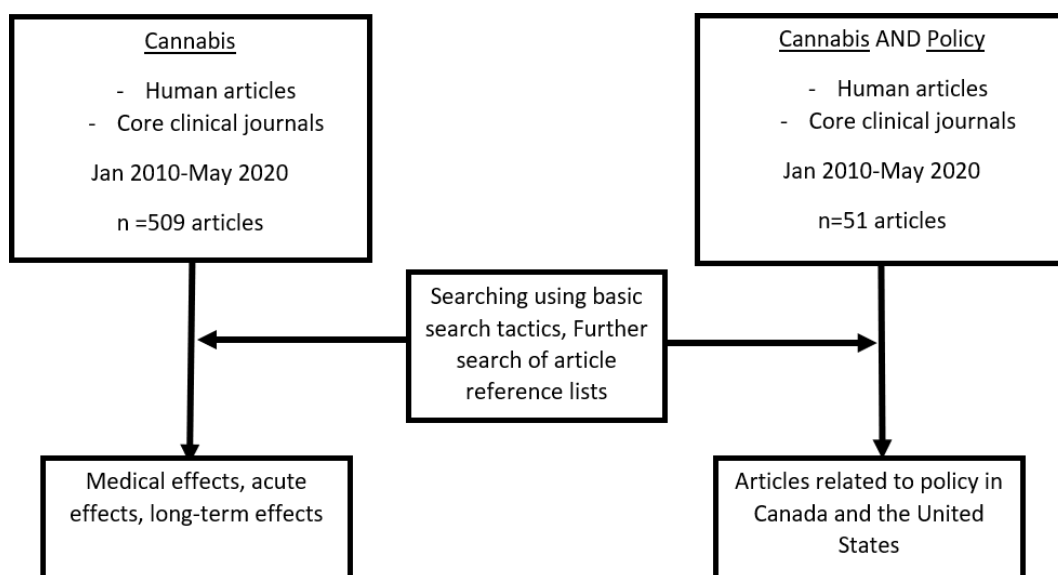

Figure 1. Search strategy for locating literature related to cannabis through MEDLINE database. Two examples of search terms were used to illustrate this strategy.

tem, resulting in neurological cognitive and motor effects, and the “high” associated with cannabis use.^{16,18} The primary nonintoxicating chemical in cannabis is cannabidiol (CBD), used more for cannabis’ medical uses such as reducing anxiety than for recreational purposes.^{14,16,18} Cannabis’ components, including THC and mainly CBD, are utilized in therapeutic treatments such as increased neural reward signaling for depression and analgesic effects for chronic pain.^{16,18} Its analgesic effects are the most established, however still require further research examining efficacy, mechanisms, and risks.^{13,15,18} Additionally, studies have found mild adverse effects on cognitive and physical function among patients using medicinal cannabis.^{13,18} This

indicates a current need for caution when using medicinal cannabis. Although cannabis has helped individuals, well-designed conclusive research, such as experiments and clinical trials, is needed to elucidate the efficacy, harms, and therapeutic potential of medicinal cannabis use.¹⁸ The topic of medicinal cannabis is controversial, further emphasizing why effective policies and better education on cannabis risks are needed – especially for the younger population.

Cannabis affects many neurological, cognitive, and systemic functions in the body; most of its known effects are related to THC. The acute effects of cannabis include disruption of sensory perception,

learning, movement, coordination, memory, attention, and executive functions (i.e. inhibition and emotional regulation). Furthermore, cannabis use may lead to euphoria, relaxation, hallucinations, cannabis-induced hyperemesis (repeated and severe vomiting episodes), anxiety, panic reactions, and psychosis.^{18,19} While there is a wide range of potential side effects, the more common acute effects include anxiety, various cognitive changes, tachycardia (fast heart rate), and certain less severe or long-term psychotic symptoms.¹⁸ Cannabis affects many neural connections in the brain including decreasing stress reactivity and glutamate (excitatory) signaling and increasing endogenous opioid release.^{14,18} Endogenous opioids are produced by the brain to act as natural pain-relieving chemicals. Altering the normal levels of excitatory glutamate and opioid production can affect the homeostasis of the body. Long-term use may result in serious chronic effects, such as mood, anxiety, and other mental health problems, loss of intelligence quotient (IQ), and increased risks of respiratory, reproductive, and cardiovascular issues.^{14,18,19} As well, chronic cannabis use is associated with brain structure and function abnormalities, especially in the limbic and prefrontal areas that are greatly affected by THC.^{18,20} These two structures are important in controlling emotion, memory, and executive functions which make them integral to everyday life. "Cannabis withdrawal syndrome" is a problem due to cannabis stimulating dopamine release in the reward signalling system of the brain.^{14,16} Therefore, the stimulation of reward signalling can result in greater addiction to the substance due to the benefits felt when taking it. Cannabis can also be a possible risk factor for altering a person's sensitivity to other related drugs.¹⁶ In rare cases, cannabis can result in death due to mixing with other substances. This can be seen in the recent crisis regarding deaths linked to vaping with THC or other compounds in the United States.²¹ Therefore, the various risks of cannabis use must be carefully evaluated against the possible benefits - especially with early onset of use.

Inhalation of cannabis comes with additional harmful effects especially pertaining to the respiratory system. As inhalation of cannabis is the most common method for consumption, providing knowledge about its increased risks is important.^{12,18,19} Inhaled cannabis can increase oxidative stress resulting in cell and tissue damage, apoptosis of cells (controlled cell death), and risk of pulmonary disorders.^{2,22} Chronic cannabis inhalation has been associated with immunosuppression in the lungs and increased risks of lung cancer, however results for the latter are inconclusive.^{12,18,22} Common symptoms include shortness of breath, chronic bronchitis symptoms including coughing and sputum, and airway irritation and inflammation.¹² Inhalation of cannabis results in a significantly higher blood THC concentration due to greater bioavailability (a higher concentration enters the blood), and a quicker and greater onset of effects when compared to oral intake.^{3,19,22} Legalization has created access to more standardized and regulated cannabis products, however a recent Canadian study found there were still many harmful chemicals such as nitric oxides, phenols, and hydrogen cyanide present in cannabis "joint" smoke resulting from multiple combustion reactions.²³ These chemicals can be carcinogenic, teratogenic and may affect fetal development, or mutagenic and may cause mutations resulting in regulated cannabis products still having potentially harmful outcomes.²³ Some of these chemicals are also in cigarettes while some are only in cannabis smoke.^{12,22,23} Therefore, inhaling cannabis, especially chronically, creates risks both from direct cannabis effects and resultant respiratory effects.

Younger Use Outcomes:

Cannabis particularly affects younger individuals physiologically and psychologically as their bodies are still growing and developing. The brain is not fully developed until around the age of 25.²⁴ Important factors such as neuronal myelination and experience-based synaptic pruning, removing unused neuron connections to increase efficiency and learning, occur at higher rates in adolescents and young adults, making this an important time for

brain development.¹⁴ Cannabis dependence seems to increase by around 8% when an individual is introduced to the substance at an early age.²⁴ This increase has been found in other studies.¹⁴ Many studies also show greater cannabis-related brain structure and function abnormalities, especially in cortical areas, and neural signalling pathway abnormalities in those with early onset of cannabis use.^{14,24} Premature use may create problems with learning and cognitive performance possibly due to the brain structure and signalling abnormalities; results on performance impairment are controversial and require further research.²⁴ Associations have been consistently found between adolescent cannabis use and risks of mood and anxiety disorders that persist into young adulthood.^{20,24,25} Research also indicated early cannabis use increased risk of psychosis even when controlling for genetic and environmental risk factors.²⁵ Factors including early onset of cannabis use, living alone, lower religiosity, greater alcohol use, and family history of mental illness (genetics) can contribute to a lower rate of discontinuation resulting in prolonged cannabis use over a lifetime.^{3,26} Using cannabis as a coping strategy, especially with early initiation, and higher frequency of use are all associated with risks of greater cannabis use severity.²⁶

Unfortunately, data recorded through Statistics Canada and Health Canada from 2004-2019 consistently show young adult populations (ages 18-24) with the highest prevalence of cannabis use in Canada.^{4,10,27} As well, the adolescent population (ages 15-17) had the second highest prevalence of cannabis use in Canada for most surveys in this time period.^{4,10,27} Overall, statistics taken in Canada have also indicated Canadian youth seem to have higher cannabis use compared to youth globally.^{27,28} Statistics have also indicated that over the years there appears to have been a decrease in cannabis' perceived risk amongst youth, which can influence them to increase their recreational use.^{3,14,26} Counterintuitively, the most susceptible individuals toward long-term harm from cannabis are most likely to use it. One study reviewing the effects of

cannabis policy changes in America over the past 25 years found that although cannabis use has recently been plateauing and even decreasing in youth (ages <18), it has been increasing continuously in young adults.¹⁷ This may be influenced in part by increased willingness to record usage; this increasing trend has been seen since as early as 2002 and other age groups have shown decreasing trends in use indicating it is not solely due to the improving social perceptions.¹⁷ As well, changes due to recreational cannabis legalization in America show the public health impacts of cannabis use such as emergency department visits have increased indicating an increase in total use or higher risk use.²⁹ This increase seems to be starting in Canada as well.²⁹ With its legalization, these figures are likely to remain high and potentially increase, especially in the legal age group of 18-24. The increased risks of cannabis consumption along with the young legal age (18 or 19) shows why regulation for Canadian young adults must be a priority.¹

Discussion

Policymaking and Health Promotion:

Policies reflecting health promotion strategies require a collaborative structural approach at both the national, provincial, and regional levels. Through the government's attempt to reduce black market sales and increase product safety, it has made public consumption more socially acceptable and created a laissez-faire attitude around its use. With this new social standard, precautions must be taken to maximize the safety of users and non-users alike. As seen in the state of Colorado, which legalized cannabis in 2012, fatal motor vehicle accidents potentially involving cannabis doubled (from 10% to 20%) over the subsequent three year period.³⁰ This indicates the importance of implementing effective and enforced safety precautions post-legalization.³⁰ If not done properly, the lack of knowledge or consideration for cannabis' effects may foster an increase in dangerous outcomes - as seen in Colorado. Reports from as late as 2015 indicate that North American rates are around 8% higher than global rates, therefore prevalence was high even before legaliza-

tion.³¹ With legalization likely increasing cannabis accessibility and use, normalizing public consumption, decreasing perceived harms, and proper regulations, policies, and educational interventions are required to ensure the safety of all Canadians.

In Alberta, although the number of municipalities with outdoor smoking policies have increased dramatically especially since 2016, currently less than half the municipalities have sufficient regulations completely inhibiting smoking or vaping on public spaces such as playgrounds and parks.³² Smoking or vaping cannabis in Alberta is restricted within 5 meters of these places, however a uniform provincial regulation restricting smoking and vaping of any substance would be more effective and easier to enforce.^{32,33} These places are highly populated, especially with children, therefore local governments in Canada need to take more action in regulating and enforcing cannabis restrictions in these public areas. University campuses require more attention as they include a large portion of the younger population, many of whom can legally consume cannabis.

Legalization largely affects Canadian university students especially since cannabis use is consistently highest among 18-24-year old in Canada.^{4,10} Results from the 4 NCHA surveys carried out at the University of Alberta suggests an increase in weekly and monthly cannabis use amongst this university population, especially recently.^{5,6,7,8} Data was collected in 2011, 2013, 2016, and 2019 showing a steeper increase between 2016 and 2019 of 10.1% in any cannabis use over the past 30 days (compared to a 0.3% increase between 2013 and 2016; a 0.9% increase between 2011 and 2013).^{5,6,7,8} Many Canadian universities have regulated cannabis use on campus through policies indicating designated areas for smoking.³⁴ Some other campuses do not have smoking areas or any uniform restrictions implemented regarding cannabis use on campus.³⁴ These policies create difficulties in regulations and are not found to be as effective at reducing on-campus cannabis use.^{35,36} Campuses require

better regulations and more uniform control of substance use all over campuses to better regulate use. The question is how Canadian universities will create a safe and healthy environment for those who smoke cannabis, those who do not, and those who only smoke or vape other substances (i.e. tobacco). Universities must also find ways to reinforce restrictions on recreational cannabis without infringing upon the rights of individuals who require medicinal cannabis. A possible way is to allow the use of ingested (not inhaled) medicinal cannabis for those that require it. Inhaled cannabis is problematic as it brings issues such as second-hand smoke, which impacts nonusers in the vicinity.³⁷ Vaporizers, also used to inhale cannabis, create challenges as they are easily concealed and can mask the characteristic smell of cannabis.³⁸ The federal government has left many regulating decisions including cannabis store locations, density of stores, and public cannabis consumption restrictions to provincial, territorial, and municipal governments.¹ Therefore, the proper creation of uniform regulations and policies by local governments as well as educational institutions is pertinent and multifaceted.

Legalization has resulted in the de-stigmatization of cannabis, however creating new rules and boundaries for cannabis has the potential to re-stigmatize it in some respects. This can occur especially if cannabis users are separated from users of tobacco and other substances in their regulations and restrictions. Therefore, it is important to uniformly address the smoking of all harmful substances on campuses and other public areas, especially since they all have detrimental effects to the users and those around them. An effective and recommended way to regulate cannabis and other harmful substances is to create a smoke-free and vape-free campus. Research has shown both smoke-free and tobacco-free campus policies result in reduced reported secondhand smoke and intention to smoke on campuses, and reduced smoking on campuses when compared to more permissive campus policies such as creating designated areas for smoking.^{35,36} As mentioned before, smoking cannabis is the predom-

inant way it is consumed with >90% of cannabis users intaking it through inhalation in 2014.^{12,18,19,31} As well, consuming cannabis through vaporizing has increased in popularity with 61% of adult cannabis users reporting using this method of administration in a 2016 study.³¹ Therefore, smoke-free and vape-free policies will reduce the majority of cannabis use on campus. This approach will prevent the creation of separate “classes” of legal drug users and will create uniform restrictions for all substances that are easier to implement and enforce on campuses. Other benefits include allowing cleaner air on campuses, fulfilling a right all individuals have. In this way, the harm to nonusers through secondhand smoke exposure will be eliminated. Secondhand smoke has known detrimental effects on an individual’s health, therefore this regulation will reduce these risks.³⁶ With this uniform policy, special considerations for students living on campus can be considered around using non-inhaled cannabis when needed while still limiting harm to others. Many youth use tobacco alongside cannabis; concurrent tobacco smoking is 6-12 times higher in adolescent and 2-5 times higher in young adult cannabis users.³¹ Information from Alberta Health also indicates a rapid increase in vaping amongst high school students from 8% in 2014-2015 to 22% in 2016-2017 when asked about use in the prior 30 days.³⁹ Therefore, banning all inhaled substances will reduce the prevalence of many harmful activities, some of which have been increasing in use, on campus and hopefully off campus as well. These policies will result in greater health promotion for those studying and working within post-secondary institutions in Canada.

The prevalence of Canadian universities with 100% smoke-free policies, even outdoors, has dramatically increased over the past three years (65 as of 2019), however many universities have not taken this step.⁴⁰ Creating a smoke-free campus will not only benefit the health of the campus population but will have other positive outcomes including decreasing costs of cleaning litter such as cigarette butts.⁴⁰ One potential way to create a smoke-free

campus is through adopting the Okanagan Charter which aims to create campuses in Canada and globally that focus on health promotion in everything they do, from policymaking to research.^{2,41} In this way, Canadian universities can align with many others, including McMaster University, Queen’s University, and the Northern Alberta Institute of Technology (NAIT), in promoting a healthy campus.² Creating a smoke-free campus aligns with the Okanagan Charter’s aim of promoting a healthy campus. Restricting orally or topically ingested recreational cannabis on campus will also contribute to promoting a healthy campus lifestyle and reducing campus cannabis use, however regulation of this is harder and less effective than regulation of inhaled substances. Universities such as McMaster University can be used as a framework for successfully promoting health over tobacco and cannabis use. McMaster University campuses went smoke-free in January 2018 to promote health and wellness which they saw as a responsibility they had to their staff, faculty, and students.⁴¹ Implementation was conducted by representatives from faculty, staff, students, and others so as to include the voices and opinions of the whole campus population in this beneficial policy.⁴¹ Many Canadian universities have taken steps in controlling cannabis on campus, however to benefit the majority of individuals there needs to be stronger and more regulated policies that include deliberation involving faculty, staff, and students.

Educational Strategies:

Not only should smoke-free policies be created to regulate cannabis use, but teaching / reminding young adults about its effects should be a priority in accomplishing a safe and healthy campus for everyone. The legalization of edibles in the fall of 2019 brings about the need for more education as there are differences between smoking cannabis and consuming it in alternate forms.⁴² As well, regulations and policies must now differentiate routes of administration as it relates in particular to the individual and nearby nonusers. As seen in Colorado, legalization of edibles increased cannabis-related harmful outcomes such as accidental intakes and

excessive intoxication due to harder dosage control and slower onset of effects.^{30,31,42} This is why a greater need exists for regulation and education compared to earlier legalization of cannabis in other forms in order to ensure population safety.^{30,31,42} Although restrictions have been placed on cannabis advertisements to reduce promotion towards youth, similar to tobacco restrictions, public education is still pertinent to reducing use.^{1,33} Educating users about the detrimental effects of cannabis is important especially when legalization has resulted in a more relaxed outlook on this drug. Social media can enhance educational interventions and increase its outreach at different universities as it is an effective way to reach most of the young adult population. This is important, especially since many large cannabis companies attempt to use poorly designed, small-scale observational or correlational studies to mislead consumers into believing benefits of cannabis that have not been proven by well-designed experimental studies.⁴³ They utilize social media and other online outlets to present these deceptive results, therefore providing properly researched scientific evidence of the effects and outcomes of cannabis through these same outlets will help promote correctly informed cannabis use.⁴³

The Canadian government has committed over \$100 million to cannabis public education, regulation, and awareness. However, it is largely the responsibility of local governments and educational institutes to create educational policies that are effective, especially pertaining to young adults.⁴⁴ When deciding how to educate the public on cannabis, many initiatives have traditionally used risk-focused messaging and 'scare tactics'.⁴⁴ This appears to be ineffective, as most individuals have not experienced the risks publicized by these strategies and young adults do not see this as a proper way to educate themselves.^{44,45} Educational interventions need to provide clear science and evidence-based information on cannabis to individuals and groups in an informative and non-antagonizing way. This includes reporting the detri-

mental effects but also the purported benefits of cannabis. Research looking at what appeals to and changes the attitudes and subsequent behaviours of individuals shows that young adults prefer novel facts and debunked myths presented so they can learn for themselves without feeling judgement or blame.⁴⁵ Providing information on the common tactics industry uses to mislead consumers is also well received.⁴⁵ The Truth Initiative in the United States is a successful example of how advertisement campaigns helped prevent around 450, 000 American youth from initiating smoking in the span of two years.⁴⁶ It also helped increase the intention for cessation in young adults and created lasting attitude changes.⁴⁶ This campaign presented short clips illustrating the harms of cannabis and exposing tobacco industry faults.⁴⁶ Many current educational initiatives target junior high and high school students. However, one point of improvement is the need to also focus on young adults as they are at a high risk for initiation and progression of substance use as they enter the legal market.⁴⁶ A harmonized approach to delivery of education between campuses and public schools with incoming students is critical. Outlining the outcomes pertaining to the younger population should also be a priority. Informing the public about resources available to help with cessation can provide a full educational outline focusing on health promotion and harm reduction. Organizing student-led educational initiatives will also improve the spread of proper knowledge through peer-to-peer discussions. Finally, providing education on all commonly used harmful substances will reduce re-stigmatization of cannabis while educating individuals on many relevant topics.

Knowing cannabis' harms will not completely stop its consumption which is why it is important to teach strategies for minimizing the risks of cannabis use. This can include information on how increased potency, higher frequency, inhaling cannabis via joints, and using synthetic cannabinoids should be avoided due to their higher risk profile.^{31,47} In this way, cannabis' harmful effects can be controlled and potentially reduced in those that choose to use this sub-

stance or who are trying to quit. The best way to create policies and regulations for young adults is to create an informative and unbiased discussion about legalized cannabis and inhaled cannabis with students across Canadian campuses. As well, this will allow public engagement and input from young adults in the creation of educational policies centered around them. In this way, the public will be effectively educated about cannabis, resulting in informed and safer use and creation of a healthier environment. With the recent crisis regarding deaths linked to vaping with THC in the United States, as mentioned above, it can be seen that a lack of educational measures for products can be life-threatening.²¹

Conclusions

Legalization of any drug brings about new challenges including appropriately structuring policy development to ensure the long-term health promotion of a society. With a drug like cannabis and its diverse methods of consumption, it is important that individuals are properly informed about its various effects. Therefore, discussion of this topic, especially with youth and young adults, should be prioritized. Additionally, Canadian governments should integrally incorporate the health of young adults into their deliberations related to cannabis. It is also the responsibility of educational institutions across Canada to prioritize the health of their campus population in the same way. The policies centered on cannabis use in Canada, including use on campuses, require more consideration and changes from where they currently are. As well, listening to Canadians' opinions and ideas on cannabis regulation is critical to creating effective rules and regulations. A priority toward smoke-free campuses and more uniform regulations with the health of all individuals in mind can result in enhanced and effective policies.

Acknowledgments

Mr. Kevin Friese, Dean of Students Office. Mr. Les Hagen, Executive Director, Action on Smoking and Health. Dr. Anne Hicks, Associate Professor FOMD. Dr. Dilini Vethanayagam, Associate Professor, FOMD.
