Prostate Cancer in Iran: Trends in Incidence and Morphological and Epidemiological Characteristics

Reza Pakzad¹, Hosein Rafiemanesh¹, Mahshid Ghoncheh², Arezoo Sarmad³, Hamid Salehiniya^{1,4,5*}, Sayedehafagh Hosseini⁶, Zahra Sepehri⁷, Amin Afshari-Moghadam^{8,9}

Abstract

Background: Prostate cancer is second most common cancer in men overall in the world, whereas it is the third most common cancer in men and the sixth most common cancer in Iran. Few studies have been conducted on the epidemiology of prostate cancer in Iran. Since ethnicity of Iranian men is different from Asian people and given the epidemiologic and demographic transition taking place in Iran, this study aimed to investigate trends of incidence and morphology of prostate cancer during 2003 - 2008 in the country. **Materials and Methods:** Data were collected retrospectively reviewing all new prostate cancer patients in the Cancer Registry Center of the Health Deputy for Iran during a 6-year period. Also carcinoma, NOS and adenocarcinoma, NOS morphology were surveyed. Trends analysis of incidence and morphology was by joinpoint regression. **Results:** During the six years a total of 16,071 cases of prostate cancer were recorded in Iran. Most were adenocarcinomas at 95.2 percent. Trend analysis of incidence (ASR) There was a significant increase incidence, with annual percentage change (APC) of 17.3% and for morphology change percentage trends there was a significant decrease in adenocarcinoma with an APC of -1.24%. **Conclusions:** Prostate cancer is a disease of older men and the incidence is increasing in Iran. The most common morphology is adenocarcinoma this appears to be decreasing over time. Due to the changing lifestyles and the aging of the population, epidemiological studies and planning assessment of the etiology of prostate cancer and its early detection are essential.

Keywords: Prostate cancer - trend - incidence - morphology - Iran

Asian Pac J Cancer Prev, 17 (2), 839-843

Introduction

Cancer is one of the main causes of death worldwide (Keyghobadi et al., 2015). It is predicted that by 2025, the incidence of cancer raises 45% in developing countries (Amoori et al., 2014). Based on the GLOBOCAN report, 14090 new cases of cancer annually occur in the world and 8202 people per year die due to cancer in the world (Ferlay et al., 2015). In some countries, cancer is the second leading cause of death among all of causes of death, but in developing countries, including Iran, cancer is a major public health problem among non-communicable diseases. So that after cardiovascular diseases and accidents is the third leading cause of death in Iran (Sadjadi et al., 2007; Mehrabani et al., 2008; Amoori et al., 2014).

One of the major cancers is prostate cancer so that it is second most common cancer in men in the world (Sadjadi

et al., 2007) and first most common cancer in American and European men (Bray et al., 2010), while in 2012, 1.1 million men suffered from prostate cancer in the world, about 70% in developing countries (Ferlay et al., 2015). Almost 42% of prostate cancer cases occur in men over 50 years (Hosseini et al., 2007) and most cases often are seen after 60 years (Pourmand et al., 2007; Pakzad et al., 2015).

Few studies have been conducted on the epidemiology of prostate cancer in Iran (Radmard, 2010), whereas it is the third most common cancer in men and the sixth most common cancer in Iran (Goya, 2007). Prostate cancer has a different geographical distribution so that in Asian countries, including Iran, is lower than in Western countries (Hosseini et al., 2007; Autorino et al., 2009; Ferlay et al., 2015). There also is the same distribution of the cancer in Iran, as the data recorded showed that standardized incidence in 2000 in Ardabil was 3.5 per

100,000 people and other studies have reported the incidence of 15.6 per 100,000 people in men (Radmard, 2010), While a study conducted in the Fars province at the same time indicated that the cancer is not one of the ten most common cancers (Mehrabani et al., 2008). Different causal factors are effective on developing the cancer. These factors can be age and nutrition (Pourmand et al., 2007). Due to changes in nutrition and also older population (Amoori et al., 2014), it can be expected to change over time the incidence of prostate cancer. A study based on data from 1996 to 2000 reported the incidence of cancer about 5.1 per 100,000 people, while the incidence reached to 12.5 in 2013, which represents an increasing trend in the incidence of prostate cancer (Ferlay et al., 2015) Depending on the different cancer types, there are different morphology such as carcinoma, adenocarcinoma, sarcoma, and others have various percentages in different cancers. However, Adenocarcinoma is the most common type of prostate cancer and prevalent in patients older than 65 years (Autorino et al., 2009). Other studies have estimated the prevalence of this type of morphology nearly 91.4% (Jamali and Moghadam, 1996). Since ethnicity Iranian men is different from Asian people and given epidemiologic and demographic transition taking place in Iran, this study aimed to investigate the Epidemiology Characteristics and Trends of Incidence and Morphology of Prostate Cancer, during 2003 - 2008 in Iran.

Materials and Methods

Data source

This analytic study was done based on longitudinal program in Iran. The data were collected from Cancer Registry Center report of health deputy which is based on Iran ministry of health guidelines (Goya, 2007). Data were collected retrospectively reviewing all new prostate cancer patients in Cancer Registry Center of health deputy for Iran during a 6-year period (2003 - 2008). Prostate cancer was defined as ICD-O C61 (Fritz, 2000). This study Survey Carcinoma, NOS and Adenocarcinoma, NOS with 8010/3 and 8140/3 morphology code, respectively.

Statistical analysis

Age-standardized rates of cancer incidence were calculated by the direct standardization method, using the world standard population as a reference. To describe incidence time trends, we carried out joinpoint regression analysis using the software Joinpoint Regression Program, Version 4.1.1.1 October 2014 (Kim et al., 2000). As well to evaluate the morphological changes, we obtained the percentage allocated for kind of morphological types. So to analysis morphology change percentage trends for

six year, we carried out joinpoint regression analysis using the software Joinpoint Regression Program. The analysis included logarithmic transformation of the rates, standard error, maximum number of one joinpoints, and minimum of six years between zero joinpoints. All other program parameters were set to default values. The aim of the approach is to identify possible joinpoints where a significant change in the trend occurs. The method identifies joinpoints based on regression models with 0-1 joinpoints. In this study 0 joinpoint (Full model) was a significant model. The final model selected was the most parsimonious of these, with the estimated annual percent change (APC) based on the trend within each segment. In describing trends, the terms “significant increase” or “significant decrease” signify that the slope of the trend was statistically significant (P<0.05). All statistical tests were two sided. Other descriptive and analytical analysis using of STATA 12 software.

Results

During the study, 9.7% of all cancers in Iranian men had prostate cancer. In total, the six-year study, 16,071 cases of prostate cancer were recorded. 79-70 year old age group with the highest number of cases to 6,783 cases (42.20%), which was related to the morphology of adenocarcinoma, was 95% (Table1).

Most cases occur after age 50 and age 80 to 84 years, is the peak risk for prostate cancer. About 96% of case occur the age group above 50 years old that this difference was statistically significant (P-Value <0.05) (Figure 1).

Epidemiological trends

Joinpoint analysis showed a significant increase in the standardized incidence rate of prostate cancer in Iran. The

Table 1. Cumulative Incidence of Carcinoma and Adenocarcinoma of Prostate Cancer, According to two Types of Morphology and of All Age Groups, During the Years 2003 to 2008

	00-09	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80-80+	Unknown	Total
Adenocarcinoma	0	0	11	34	172	1298	4033	6485	2895	373	15301
Carcinoma	0	0	0	0	3	16	39	65	43	2	168
Total	3	1	12	39	183	1390	4179	6783	3067	411	16071

Table 2. Frequency, Crude and Standardized Incidence of Prostate Cancer and the Total Number of Cancer Cases by Sex, During The Years 2003 To 2008

	The number of cases of prostate cancer (men)	The total number of cases of cancer in men (percent)	Total cancer cases (men and women)	CIR	ASR
2003	1548	21619 (2/56)	38468	4.54	5.40
2004	2072	26743 (6/56)	47217	5.97	7.24
2005	2722	31355 (1/56)	55853	7.53	9.22
2006	2817	33770 (49/56)	59786	7.82	9.57
2007	3179	34636 (81/55)	62040	8.79	10.91
2008	3733	42279 (51/55)	76159	10.37	12.80

Table 3. Change in the Percentage Allocated to the Morphology of Carcinoma, Adenocarcinoma and Other Morphological Data (2008-2003)

	2003 – 2008		2003 – 2006		2006 – 2008	
	AAPC	95% CI	APC	95% CI	APC	95% CI
Carcinoma	5.9	-43.1 to 97.1				
Adenocarcinoma	-1.4*	-1.8 to -1.1	-0.2	-2.3 to 2.0	-3.3	-7.4 to 0.9
Other	42.7*	12.3 to 81.3				

*APC and AAPC is significantly different from zero at alpha = 0.05

annual percentage change (APC) for cancer incidence was equal to 17.29% (CI: 11.1 to 23.9) (Table 2).

Morphological Trend

The morphology of adenocarcinoma with 15301 cases (95.21%) and carcinoma in 168 cases (1.04%) were the most common morphology. Significant differences between the morphology of prostate cancer and the different age groups was not observed (P -Value>0.05) and nearly all the morphological occur more in older age (Table 1). Adenocarcinoma in 2003 and 2008, respectively, 97.61% and 90.97% of total prostate cancer accounted. Dedicated to the trend of changes in most common morphology (adenocarcinoma) annual percentage changes (APC) showed a significant decrease (Table 3).

Discussion

Our findings showed that the majority of cases (96%) occur after 50 years and the high incidence was 80 to 84 years .a study (Fatemah Haghghi et al., 2005) conducted in Birjand (East of Iran) showed more cases occur after 50 years and prostate cancer is the most frequent in the ninth decade of life (80 years and above), which is consistent with the results of this study.

In another study in the Fars province, it also found that 99% of cases occur in man over 50 years and the highest incidence of cancer is at the age of 80 years (Farahmand et al., 2013). A study in the Khuzestan province showed that more than 99% cases were 45 years and the high incidence was 75 to 84 years (Amoori et al., 2014).

A another study conducted in the Babol city also found that the highest age of developing cancer was 70 years (Hahiyani et al., 2003) and Basiri also showed that the maximum age was 70 years (Basiri et al., 2014). One study was conducted in Turkey showed that the maximum age for the incidence cancer was 75 to 79 year (Eser et al., 2009) and Another study reported in Greece the incidence

was 70- to 75 years (Grivas et al., 2012), This difference may be due to differences in the age composition of the population.

As the incidence of prostate cancer increases, the age increases (Eser et al., 2009) and after 50 years it raises with a steep ascent (Muir et al., 1991; Fatemah Haghghi et al., 2005; Grivas et al., 2012; Farahmand et al., 2013). However, in another study in America it was as steep as after 65 years (Gronberg, 2003). In a study it was in Turkey 40 years (Zorlu et al., 2014) and in Greece 45 years reported (Grivas et al., 2012). This could be due to racial differences and genetic and environmental factors, such as diet, environment, occupation, smoking, and other unknown risk factors.

In this study, the standardized incidence of prostate cancer in 2003 to 2009 was 5.4, 7.24, 9.22, 9.57, 10.91, and 12.80 cases per 100,000 people, respectively. According to the GLOBOCAN report in 2002, the age standardized incidence rate of prostate cancer in the world was 25.3 cases per 100,000 people so this rate in developed countries (the highest was related to United States (U.S) was 56.2 and in developing countries, 9.4 cases per hundred thousand people (the minimum for Bangladesh) (Baade et al., 2009; Jack et al., 2010). Also the rate in Greece between 1999 to 2004 was 26 per hundred thousand people (Grivas et al., 2012), but the rate in 2002 have been reported about 3.5 per hundred thousand people in the Fars province (Masoompour et al., 2011) and in this study it was 5.4 per hundred thousand, which reflects the low rate of this cancer in the Iran compared to other countries.

This rate in Turkey in 2006 was equal to 22.8 (Eser et al., 2009) and in Greece had risen to 42 per hundred thousand people until 2010 (Grivas et al., 2012). Also in developed countries in 2008 it has increased to 62 cases and in the developing countries to 12 cases per hundred thousand people (Jemal et al., 2011). In this study, the rate was 12.8 per hundred thousand people. This shows

that the country is better for the development so prostate cancer increases. This could be due to improved reporting systems in developing countries and developed countries versus less developed countries. Although some of this difference could be real. The standardized incidence rate in this study was lower than developed and developing countries. However, the increasing trend over the years has been globally observed. This could be due to better detection tests, an aging population, and a real increase in the world. At the same time, however, the incidence of prostate cancer has been decreasing in most European countries (Bray et al., 2010). This can be due to screening programs that have already been implemented in the community.

The highest incidence in this study occur in 2008, similar to the incidence in developing countries (Jemal et al., 2011), while in another study greatest incidence was 16.65 in 2007 and with slight differences the incidence of 16.02 in 2008 was ranked as second (Farahmand et al., 2013). This may be due to differences in population, better detection methods, or whether this difference is real. However, the findings of this study are consistent with increasing incidence.

In the present study, the morphology of Adenocarcinoma was the most frequent type with 95.21% percent and carcinoma is the most common, followed by 1.04 percent. In a study showed that morphology with adenocarcinoma was greatest with 91.2 percent (Esmail Nasab N, 2007). In another study, the type of adenocarcinoma with 91.7% was allocated to the most common type (Fatemah Haghghi et al., 2005). General Urology by smith, stated that more than 95% of prostate cancers were adenocarcinoma (Fatemah Haghghi et al., 2005). In another study based on samples taken in Imam Khomeini Hospital, Pathology Center (SID) and the center of Pathology, School of Medicine, Yazd, the most common types were adenocarcinoma, 91.4%, 84.7% and 71%, respectively (Jamali and Moghadam, 1996). All these findings are consistent with each other and show that the most common type morphology of cancer in Iran. In a study in Saudi Arabia and Pakistan, adenocarcinoma is also the most common type morphology (Arshad and Ahmad, 2013; Albasri et al., 2014).

In addition to the lower prevalence of risk factors for prostate cancer, incomplete and the lack of comprehensive programs especially in the case of prostate cancer, breast, and colorectal cancer can be one of the main reasons for low as well as in developing countries (Mousavi et al., 2009). These limitations can lead to underestimation of the true extent of this type of cancer (Masoompour et al., 2011). In other studies, one of the most important factors of prostate cancer in developed countries was comprehensive review of the prostate cancer screening program with use of PSA (prostate specific antigen) (Jemal et al., 2011; Belbase et al., 2013).

Based the results of this study and other similar studies (Farahmand et al., 2013) have been identified in Iran that this type of cancer had the slight increase in the past years that may indicate that cancer registration data is better.

Based on these results and considering the prevalence of prostate neoplasms and adverse effects, it is suggested that most epidemiological studies in order to identify

regional risk factors and lifestyles, application new screening methods for early diagnosis of latent prostate cancer .
