

EXAMINING CORRELATES OF METHAMPHETAMINE AND OTHER DRUG USE IN PREGNANT AMERICAN INDIAN ADOLESCENTS

Allison Barlow, MA, MPH, Britta C. Mullany, PhD, MHS, Nicole Neault, MPH, Yvonne Davis, MPH, Trudy Billy, Ranelda Hastings, Valerie Coho-Mescal, Kristin Lake, MPH, Julia Powers, MHS, Emily Clouse, Raymond Reid, MD, MPH, and John T. Walkup, MD

Abstract: American Indian and Alaska Native (AI/AN) adolescents have high rates of pregnancy, as well as alcohol, marijuana, cocaine, and, increasingly, methamphetamine (meth) use. The progression of adolescent drug use to meth use could have devastating impacts on AI communities, particularly when youth are simultaneously at risk for teen childbearing. In order to inform future prevention efforts, this study explores correlates of meth use in a sample of pregnant AI teens, with a focus on sociodemographic, familial, and cultural factors and use of other drugs.

INTRODUCTION

Increasing use of methamphetamine (meth) among adolescents in the U.S. is a serious public health problem, with long-lasting medical, psychosocial, and societal consequences. Meth is a highly addictive drug that causes sustained structural changes in the brain, and cognitive and emotional problems in chronic users. It is also associated with a constellation of other unsafe behaviors and with the spread and progression of HIV and other infectious diseases, such as Hepatitis B and C (National Institute on Drug Abuse, 2009). Nationally, an estimated 4.3% of people aged 12 years and older (Substance Abuse and Mental Health Services Administration, 2006) and 4.5% of high school seniors (Johnston, O'Malley, Bachman, & Schulenberg, 2006) have used meth at least once. Use of meth among adolescents has been found to follow use of alcohol, marijuana, and other illicit drugs (Novins, Beals, & Mitchell, 2001). American Indian/Alaska Native (AI/AN) adolescents, in general, report higher lifetime and past year use of illicit drugs than any other racial or ethnic group (Substance Abuse and Mental Health Services Administration, 2008). Between 2006-2008, approximately 3 times more AI/ANs aged 12 years and older vs. U.S. All Races (1.4% vs. 0.54%) reported using meth in the past year (National Institute on Drug Abuse, 2006).

Considering nearly 2 times as many AI/AN females begin childbearing in adolescence, and bear twice as many children while teenagers as the general U.S. population (Indian Health Service & Department of Health and Human Services, 2001), increasing use of meth among AI/AN adolescents poses significant lifetime risks for young AI/AN mothers and their children, families, and communities. Prenatal meth exposure has been linked to fetal growth restriction, cardiac anomalies, clefting, and neurocognitive defects (Plessinger, 1998; Smith et al., 2003; Chang et al., 2004; Smith et al., 2006). Early childhood exposure to parental meth use is associated with exposure to environmental toxins and dangers, neglect, abuse, and insufficient bonding and nurturing (Haight et al., 2005). More generally, adolescent childbearing has been linked with both drug use and negative parenting practices that predict higher drug use in offspring (Ashery, Roberston, & Kumpfer, 1998). Thus, the intertwining risks of teen pregnancy and drug use among AI/AN adolescent girls may be a critical contributor to multigenerational drug dependence and related behavioral health disparities among AI/AN populations (Howard et al., 1999; Barlow et al., 2006; Walkup et al., 2009). This situation begs further understanding of population-specific risks and potential prevention strategies.

Recent studies have identified risk and protective factors for meth use among youth in the general U.S. population. Risks include: fewer years of education; homosexuality and bisexuality; history of psychiatric disorder; family history of drug use; use of alcohol, cigarettes, marijuana, and heroin/opiates; and peer pressure and the presence of drug-using friends (Russell et al., 2008; Shillington et al., 2005; Sattah et al., 2002). Reservation-based AI adolescents face additional environmental risks that may contribute to higher rates of drug and meth use, including a history of cultural and political oppression, high unemployment and school dropout rates, geographic isolation, underresourced law enforcement agencies, and lower access to services to prevent and treat drug use (Barlow et al., 2006; Walkup et al., 2009; Barlow & Walkup, 1998; Barlow & Walkup, 2008; Office of Technology Assessment, 1990). AI/AN communities also have unique protective factors against drug use, including traditions that support strong linkages to family and clan networks, as well as cultural beliefs and practices that promote alcohol and drug abstinence and maintenance of pure body and mind during pregnancy (Barlow & Walkup, 1998; American Indian Families Project, 2004; Rogers, 2001; Szlemko, Wood, & Thurman, 2006).

As a step toward prevention in AI reservation settings, the goal of this study was to explore demographic, familial, and cultural correlates of meth and other drug use among 322 expectant AI adolescents enrolled in a trial of a home-visiting intervention called Family Spirit (Barlow et al., 2006; Walkup et al., 2009). Family Spirit is designed for delivery by local Native paraprofessionals in their reservation communities, and aims to reduce maternal and child risks for lifetime drug use. The theoretical model underpinning the Family Spirit intervention is based on G.R. Patterson's

theory of how children develop behavior problems (see Patterson, DeBaryshe, & Ramsey, 1989). Patterson's model posits that ineffective parenting mediates a variety of poor child behavior outcomes; conversely, positive parenting protects against the onset of negative behaviors through early, middle, and later childhood.

Consistent with the theoretical model and the behavioral target of the intervention, the primary aim of the baseline analysis conducted for this study was to investigate relationships between drug use and expectant mothers' family of origin functioning. We hypothesized that mothers who reported higher drug use would report lower family functioning. Further, we hypothesized that stronger affinity with traditional values would correlate with both more positive family functioning and lower drug use. In keeping with Patterson's model, we hypothesized that negative demographic factors could exacerbate poor family functioning and ultimately affect mothers' capacity for positive parenting if not addressed. To explore the spectrum of drug use severity, we viewed lifetime and pregnancy meth use and pregnancy use of any drugs as the strongest indicators of drug use risk. We also looked at relationships of meth use to other drug use, to understand the patterns of drug progression in this sample.

METHODS

Data Collection

Data were collected at the baseline assessment of the intervention trial, prior to the participants being randomized. The sample included 322 expectant females, aged 12-19 years at the time of conception, from four rural reservation communities in the Southwest (referred to as Sites 1-4). Baseline data were collected from expectant teens between 14 and 35 weeks' gestation (median = 25 weeks) during the period June 2006 to May 2008.

The baseline assessment included a semi-structured interview that elicited sociodemographic and cultural identity information, and standardized self-report questionnaires on drug use and family functioning. AI study personnel administered assessments in participants' homes, or another confidential setting (e.g., vehicle or site office) if requested by the participant.

Measures

Semi-structured Interview. Sociodemographic information, including participants' age at conception, parity, marital and educational status, current use of food stamps, number of homes lived in during previous year, and drug use since the time of conception, was collected via a semi-

structured interview. The interview was compiled primarily from the Voices of Indian Teens instrument (Moran, Fleming, Somervell, & Manson, 1999) and a demographic survey that had been developed by the investigators, via an iterative process with Native paraprofessionals, for this and two previous studies (Barlow et al., 2006; Walkup et al., 2009).

Voices of Indian Teens (Moran, Fleming, Somervell, & Manson, 1999). The VOICES survey is the product of a rigorous formative and instrument development project conducted with two AI communities that has been found to have acceptable reliability and validity (Mitchell, Beals, & Whitesell, 2008). Selected components of the survey used in this study included questions on cultural identity and family history of suicide. Parental alcohol abuse was measured using a VOICES question that asked participants to indicate whether their birth mother or birth father currently has or in the past had a “serious drinking problem.” VOICES questions about drugs were also used, including a 13-item self-report questionnaire measuring lifetime use, use in past 30 days, and age at first use of alcohol, marijuana, crack/cocaine, meth, barbiturates, and inhalants.

Problem Oriented Screening Instrument for Teenagers (POSIT), Family Relations (range 0-11, Cronbach’s alpha 0.75; Rahdert, 1991). The POSIT is widely used to assess a broad range of functional areas among teens. The instrument has 139 self-report items encompassing 10 functional subscales. The subscale measuring family functioning was included in this study. This subscale is derived from individuals’ responses to 11 yes/no questions, with approximately half of the items being reverse-scored. For clinical and research purposes, the family functioning subscale is typically dichotomized into two categories (low and high risk), based on whether the subscale score exceeds a given cutoff value (i.e., 0-3 indicates low risk; ≥ 4 indicates high risk). The POSIT is designed to flag functional problem areas, but is considered conservative in that a ‘high’ risk score is suggestive, but not definitive, of potential underlying problems (Rahdert). Psychometric data on the POSIT indicate high reliability and validity of the instrument (Gruenewald & Klitzner, 1991), and the instrument has been found to be an effective screening tool for maladaptive family functioning among African-American and Latino adolescent drug users (Santisteban, Tejada, Dominicis, & Szapocznik, 1999).

ANALYSIS

Given the rapid rise of meth in many AI/AN communities, as well as the serious public health and societal consequences associated with its use, our analysis focused primarily on meth use. Two time periods for meth use were created for analyses of correlates. Lifetime meth use was defined as positive when participants noted “ever having tried” meth on the self-report questionnaire. Pregnancy meth use was defined as positive when participants reported (a) using meth since conception during the semi-structured interview, or (b) using meth in past 30 days on the self-report questionnaire.

Due to the increased risks associated with young age (≤ 15 years) at first drug use (Kumpfer, Alexander, McDonald, & Olds, 1998), variables representing ages of participants were dichotomized into two age groups: 12-15 and 16-19 years. Due to limited variation in the distribution of cultural identity items, the 4-point Likert measures were collapsed into two groups (i.e., “Not at all/Not much” versus “Some/A lot”). In interpreting outcomes, the dichotomized groupings of cultural identity were used to differentiate positive or negative affinity with traditional cultural beliefs and practices. (However, the authors recognize that cultural affinity is, in practice, a dynamic and continuous variable, and therefore, the collapsing of positive and negative cultural affinity scores presents a limitation in this study.) Binary variables for alcohol, marijuana, or crack/cocaine use during pregnancy were based on drug use since conception or in past 30 days. Barbiturate and inhalant use during pregnancy were too infrequent ($n = \sim 1-2$) for analysis. The POSIT family functioning scale was dichotomized into low (0-3) and high (≥ 4) risk scores, according to the manual instructions regarding clinical cutoff scores (Rahdert, 1991; Santisteban et al., 1999).

Factors associated ($p < 0.05$) with meth use in bivariate analyses were included in multivariate models. Because our sample contained only 17 individuals who had used meth during pregnancy, we expanded the multivariate analysis to include a model of any drug use during pregnancy (i.e., meth, marijuana, crack/cocaine, inhalants, barbiturates, or alcohol). Examination of other drug use during pregnancy is of special interest in understanding intervention needs because of its potential to signal drug use severity, progression, and dependence.

Relative risks (RR) for meth or any drug use were calculated by using modified Poisson regression with robust variance estimation, considered the optimal approach for cross-sectional analysis of relatively frequent outcomes (Barros & Hiraakata, 2003; Zou, 2004). RR, a commonly used measure in statistics and epidemiology, is a ratio of the probability of an event or outcome (in this case, drug use) occurring in an exposed versus an unexposed group (i.e., high-risk family functioning versus low-risk family functioning group). While RR is similar to the odds ratio in terms of measuring associations of risk between two variables, it is considered more accurate and appropriate in measuring associations with outcomes that are relatively frequent. Because drug use in this sample was relatively frequent, RR was determined to be the more appropriate measure for this analysis.

Variance inflation factors (VIF) were calculated to test for multicollinearity between covariates. Given high correlation levels ($VIF > 5$; O'Brien, 2007) between lifetime and pregnancy use of substances, multivariate models of pregnancy use excluded lifetime use. Ages at first use for different substances were not included in multivariate models due to reduction in sample size if those variables were used. Exploratory chi-squared analysis was conducted to compare meth and other drug use patterns across individual POSIT family functioning items.

All analyses were conducted using Stata 9.2. Missing data were minimal (< 1% of values). The study protocol was approved by the Johns Hopkins Bloomberg School of Public Health IRB, Indian Health Service (IHS) IRB, and appropriate tribal IRBs and health boards. The manuscript was approved by all relevant tribal and IHS IRBs.

RESULTS

Sociodemographic, Family, and Cultural Characteristics and Drug Use History

This sample of expectant AI women was young (mean age = 17.6 years), unmarried (97%, n = 311), out of school (59%, n = 191), and highly mobile (51%, or n = 163, lived in 2 or more homes in the previous year). Nearly one quarter (23%, n = 75) had more than one child (See Table 1). Over one third (37%, n = 119) had a family functioning score above or equal to the clinical cutoff indicating high risk for problems in family functioning. More than half (58%, n = 188) reported having at least one parent with a serious drinking problem according to the VOICES self-report item. Approximately 5% (n = 14) had lost an immediate family member to suicide. In terms of cultural identity, 47.5% reported living a traditional way of life vs. 52.5% who said they did not. One third (33.9%) ascribed high importance to having traditional Indian values vs. 66.1% who said living traditionally was less important.

Drug Use History

More than one quarter of participants (26%, n = 83) reported using meth at least once in their lifetimes (Table 1). Reported lifetime meth use was one third of reported alcohol (78%, n = 250) or marijuana (75%, n = 241) use, nearly the same as lifetime crack/cocaine use (23%, n = 75), and approximately 5 times higher than barbiturate or inhalant use (5-6%, n = 17 and n = 21, respectively). Almost half (48%, n = 155) of the sample said they had ever used cigarettes, and 19% (n = 62) reported using cigarettes at least once during pregnancy. Of these 19%, the majority (n = 54; 87%) said they smoked cigarettes occasionally, but not every day, while the remaining 8 respondents (13%) reported smoking 1-10 cigarettes per day.

Approximately 1 in 20 (5.3%, n = 17) reported meth use during pregnancy prior to study enrollment (mean gestational age, 25 weeks). Substances used most during pregnancy were alcohol (14%, n = 45) and marijuana (13%, n = 43).

Initiation of meth use occurred at older ages than for all other substances (mean = 15.7 years). Inhalants were initiated earliest (mean = 13.6 years), followed by marijuana (mean = 14.0 years), tobacco (mean = 14.2 years), then alcohol (mean = 14.6 years).

Table 1
Participants' Drug Use History (N = 322)

Drug Use Characteristics	Lifetime Drug Use n (%)	Pregnancy Drug Use n (%)	Age at First Use Mean (SD)
Alcohol	250 (77.6)	45 (14.0)	14.6 (1.8)
Marijuana	241 (74.8)	43 (13.4)	14.0 (2.1)
Methamphetamines	83 (25.8)	17 (5.3)	15.7 (1.7)
Crack/cocaine	75 (23.3)	6 (1.9)	15.4 (1.7)
Barbiturates	21 (6.5)	3 (1.0)	15.3 (2.0)
Inhalants	17 (5.3)	1 (0.3)	13.6 (2.1)
Any of above drugs	276 (85.7)	81 (25.2)	NA
Never used any drugs	46 (14.3)	241 (74.8)	NA

Factors Associated with Lifetime and Pregnancy Meth Use Risk

Bivariate test results examining factors associated with increased or decreased likelihood of lifetime or pregnancy meth use are shown in Table 2. Factors most strongly associated with increased lifetime meth use included southern or central geographic locations; high residential mobility; poor family functioning; parental history of alcohol problems; family history of suicide; and lifetime and pregnancy use of alcohol, marijuana, crack/cocaine, barbiturates, and inhalants. Currently attending school, living by traditional way, greater importance ascribed to traditional Indian values, and older ages of initiation of alcohol and marijuana were all associated with decreased lifetime meth use. Although not shown in this table, similar geographical patterns were seen for lifetime and pregnancy use of alcohol, marijuana, and crack/cocaine, with the southern and central locations having the highest levels of use.

Correlates of Risk

Lifetime Meth Use

Geographic location, family functioning, parental alcohol abuse, and lifetime use of marijuana, crack/cocaine, and inhalants were all independently associated with increased risk of lifetime meth use (Table 3). After controlling for covariates, participants at Site 2 were more likely to report lifetime meth use (RR = 2.53, *p* < 0.005). Regardless of study site, those with higher family dysfunction were 1.44 times (*p* < 0.05) more likely to use meth, compared to those with lower family dysfunction. Findings also suggest that participants who reported having a parent with a serious drinking problem were 1.36 times (*p* < 0.1) more likely to use meth. Controlling for

lifetime use of all other substances, participants who had ever used marijuana were more than 5 times more likely to have ever used meth than non-marijuana users (RR = 5.23, $p < 0.05$); crack/cocaine users were approximately 4 times (RR = 3.96, $p < 0.005$) more likely; and, inhalant users, 1.5 times more likely (RR = 1.51, $p < 0.05$).

Exploratory Analysis of Pregnancy Meth and Other Drug Use

Two independent models of substance use during pregnancy were created: one for any substance use (including meth, alcohol, marijuana, crack/cocaine, barbiturates, or inhalants), and one specifically for meth use. Participants at Site 3 were significantly less likely to use meth (RR = 0.04, $p < 0.005$) or any substances during pregnancy (RR = 0.25, $p < 0.005$) than participants at Site 1. Participants who had lived in four or more homes vs. one home in the previous year were twice as likely to use any substances during pregnancy (RR = 1.98, $p < 0.05$). Participants who reported parent abuse of alcohol were 1.76 times more likely to report substance use during pregnancy ($p < 0.05$). Having an immediate family member who had committed suicide quadrupled participants’ risk of meth use and doubled risk of any substance use during pregnancy (RR = 4.25 [$p < 0.05$] and RR = 2.22 [$p < 0.05$], respectively). Individuals who ascribed greater importance to practicing traditional Indian values were less likely to report meth or any substance use during pregnancy (RR = 0.17 [$p < 0.1$] and RR = 0.42 [$p < 0.005$], respectively).

Exploratory Analysis of Family Functioning and Meth and Other Drug Use

Table 4 reports chi-squared results for associations between POSIT family functioning scale items, lifetime meth use, and use of meth or any other drugs during pregnancy. Lifetime meth use was consistently associated with higher family dysfunction scores. Individuals with high vs. low family dysfunction POSIT scores also began alcohol and marijuana use at younger ages (14.1 vs.

14.9 years for alcohol, $p < 0.001$; 13.7 vs. 14.3 years for marijuana, $p < 0.05$), and earlier initiation of drug use correlated with meth use. For every POSIT item, there was a greater proportion of women who had “ever used” meth in the higher family dysfunction category, with 7 of 11 items reaching significance at the $p < 0.05$ level and 3 of 11 at the $p < 0.1$ level. Similar POSIT patterns were found for use of meth or any drugs during pregnancy. POSIT items most strongly associated with lifetime and pregnancy drug use included, “Do your parents/guardians argue a lot?” and “Do you and your parents/guardians have frequent arguments which involve yelling or screaming?” Items negatively correlated with drug use included, “Do your parents/guardians and you do lots of things together?” and “Do your parents/guardians have a pretty good idea of your interests?”

Positive family functioning, as measured by the POSIT, was also associated with traditional cultural affinity. For example, 71% of those who said they lived a traditional way of life had positive family functioning vs. 56% who did not believe living a traditional way of life was important ($p < 0.01$). Similarly, 72% of respondents who felt it was more important to have traditional Indian values had positive family functioning, versus 58% of respondents who reported it was less important to have traditional Indian values ($p < 0.05$; data not shown).

DISCUSSION

Drug Use

Lifetime meth use in this sample of pregnant AI teens was up to 3 times higher than among previous national samples of AI/AN adolescents (Oetting et al., 2000) and approximately 5 times higher than U.S. All Races adolescents (Springer, Peters, Shegog, White, & Kelder, 2007; Johnston et al., 2006). Past-month use of meth (2.5%) was double past-month use in comparable samples of U.S. All Races youth (Iritani, Hallfors, & Bauer, 2007). Reported meth use during pregnancy (5.3%) was approximately 5 times higher than recent national samples of pregnant women (National Institute on Drug Abuse, 2006).

Mean age at first meth use (15.7 years) was considerably lower than among the general U.S. population (22.1 years in 2004; Substance Abuse and Mental Health Services Administration, 2006). Generally consistent with gateway theory (Kandel, 1975), exposure to meth in this sample occurred later than exposure to other legally available substances (alcohol and inhalants) and marijuana and crack/cocaine. However, in contrast with gateway theory findings in other U.S. adolescent populations (Willner, 2001), participants were more likely to initiate marijuana use prior to alcohol use and had equal exposure to alcohol and marijuana (77.6% vs. 74.8%). Meth use was more highly correlated with marijuana use than with use of alcohol, cocaine, or any other drug. This finding is consistent with another large prospective study of western AI adolescents, which showed that initiation of marijuana use prior to alcohol use increased the risk of substance use progression (Novins & Barón, 2004). Further study is needed to determine if teen pregnancy and early initiation of marijuana use are linked risk factors for substance use progression. Early marijuana use should be an indicator for intervention in the AI communities participating in this study, and potentially in other similar AI/AN communities.

Correlates of Drug Use Risk

Sociodemographic Factors

We found no differences in meth use related to education or marital status, age at conception, parity, or use of food stamps, which may be a function of the limited variability in socioeconomic status among the participating communities. However, we found that geographic location was strongly correlated with meth use risk. The four participating communities vary somewhat in population (ranging from approximately 13,000 to 27,000) and are located on three different reservation lands that differ in topography and proximity to urban areas. Site 2, which had the highest lifetime and pregnancy meth use rates, is the southernmost site and is closest (1-2 hours)

to two large urban population centers. Site 3, which had the lowest rates, is the northernmost and the most geographically distant (> 4 hours) from urban centers. Sites 1 and 4 are in between with respect to geographic isolation and drug use risk. Differences in levels of drug trafficking from southern urban centers may influence adolescents' exposure and use. For example, drug traffickers from Mexico, which controls 70-90% of meth production and distribution to the U.S., may exploit the southernmost AI reservations, which generally have fewer law enforcement resources and face complications in applying legal consequences to outsiders (Brouwer et al., 2006). However, the fact that other drug use was also higher in the sites with high meth use complicates the picture, but may mean that other drug exposure is necessary and facilitates the uptake of meth.

After adjusting for site in multivariate models, family dysfunction and residential instability remained significant risks, and traditional cultural affinity remained significantly protective. High residential mobility in this sample was also correlated with greater family dysfunction (42% of those who had lived in ≥ 2 homes in the previous year had high family dysfunction scores, as compared to 31% of those who had lived in only one home, $p < 0.05$).

Family factors

Family factors correlated with meth use in this sample hold clues for prevention. Teen mothers who reported growing up in families with poor functioning and high conflict (e.g., parents who frequently argued, yelled), as measured by the POSIT, were at greatest risk for lifetime meth and pregnancy drug use. In contrast, teens who felt understood by their parents/guardians (e.g., parents/guardians have "good idea of my interests") had lower drug use. These findings are consistent with child development theories indicating that ineffective parenting leads to a variety of poor child behavior outcomes (Patterson et al., 1989), including drug use, and predict drug use will be perpetuated across generations in the absence of family-based intervention.

Our exploration of correlations of severe drug use with other indicators of family dysfunction yields several directions for future research. Parental history of alcohol problems and family history of suicide were correlated with the most severe drug use risk, including pregnancy use of meth and other drugs. We hypothesize that these mothers' serious drug use may be correlated with a more severe history of family dysfunction. The role of family history of psychiatric disorders is unknown in this sample, and is an important piece of the puzzle in understanding the constellation of family-based risks for drug use. Further research is needed to target reduction of children's *in utero* exposure to drugs and the perpetuation of negative mental health outcomes across generations in Native and other similarly challenged communities.

While a growing body of studies has demonstrated that positive parenting interventions are preventive for lifetime child behavior risks (Kumpfer & Alvarado, 2003; Etz, Robertson, & Ashery, 1998), rigorous trials with AI/AN reservation communities have been scarce (see Novins, 2009). Baseline data from the current trial regarding family-based risks that affect drug use among teen mothers, and ultimately the ability of the Family Spirit intervention to reduce drug use in AI teen mothers and their offspring, holds high public health significance for Indian communities.

Cultural factors

Participants who ascribed importance to having strong traditional Indian values were less likely to use meth and other substances during pregnancy, and were also more likely to have positive scores (i.e., low risk of problems) for family functioning. Strong cultural identification has been shown to be protective against substance use among other populations, as well as AIs (Castro et al., 2007; Szlemko et al., 2006). AIs have unique traditions that view pregnancy and childbearing as spiritually sacred (Cesario, 2001). The participating tribes have special cultural practices during pregnancy to honor and protect the growing child spirit, such as avoiding negative thoughts or foreign foods or smells. Engagement in unique traditional Native customs and beliefs has potential to strengthen drug prevention efforts among pregnant AI/AN women. Further, the fact that the majority (80%) of females who used meth in their lifetime did *not* use meth during pregnancy may indicate that pregnancy presents a distinct opportunity for behavioral redirection.

Limitations

There are several limitations to this study. Given the cross-sectional nature of the analyses, we are unable to make assumptions regarding causality of the identified associations. The small sample size and relatively small numbers of teens who used meth ($n = 17$) or any drugs ($n = 81$) during pregnancy limited our ability to draw definitive conclusions. The generalizability of our findings is also limited by potential sampling bias, as we only included AI adolescents who agreed to participate in the Family Spirit intervention study. We suspect that the expectant teens who enrolled in the trial may have had lower meth use risk than their communities' pregnant teen populations at large. Further, substance use, especially illicit drug use, is historically susceptible to underreporting among youth. Our sample may have viewed reporting sensitive information about drug use during and prior to pregnancy as socially undesirable, potentially yielding lower estimates. Family history of drug use is also susceptible to underreporting by adolescent populations.

Meth use estimates during pregnancy were also potentially problematic. In an effort to provide the most statistically robust estimates, the variable for pregnancy meth use was created by combining two questions (use of substance since time of conception, when participants may

not have known they were pregnant yet, and use of substance during past 30 days of pregnancy, when participants knew they were pregnant). Upon running the same multivariate models for the individual questions, similar trends were seen, but with diminished statistical significance. Further, the pregnancy usage captured only the time from conception to study enrollment (mean gestational age 25 weeks) and not use during the third trimester, once again potentially resulting in underestimates of pregnancy use. Finally, dichotomizing groups related to the cultural identity scales potentially oversimplifies the interpretation of participants' cultural affinity.

CONCLUSIONS

High reported rates of meth and other drug use among this sample of expectant teens support disparities found among other AI/AN populations and increase the urgency for determining effective substance abuse prevention strategies among AI/AN adolescents, especially those at risk for pregnancy. The strong association of family and traditional cultural factors with meth and other substance use within this sample suggests that further research on the utility of culturally driven family strengthening approaches to prevent children's drug use is warranted within AI/AN populations. While expectant AI/AN teens are exposed to multiple environmental risks, pregnancy and early childbearing may provide a pivotal developmental time point for effecting lasting behavior change in ways that tap local cultural strengths. Because a large proportion of AI/AN women begin childbearing as teenagers, the success of such interventions has important public health significance to breaking multigenerational cycles of drug abuse.

ACKNOWLEDGEMENTS

We respectfully acknowledge the mothers and children who participated in this study, and all study team members. We give thanks to tribal leaders and community stakeholders who generously contributed time and wisdom to shaping the research protocol and reviewing this manuscript. We deeply hope the results will guide effective intervention strategies. We are grateful to IHS for their long-standing collaboration in health promotion and for their review of the research and manuscript. Financial support for this work was provided by the National Institute on Drug Abuse (R01 DA019042). *Disclaimer:* The opinions expressed are those of the authors and do not necessarily reflect the views of the IHS.
