1 The main hydroxamic acid in maize (Zea mays L.) is 2-4-dihydroxy-7-methoxy-1,4-benzoxazin-3-one (DIMBOA). 2 DIMBOA confers resistance to leaf-feeding by several corn borers. Most genes involved in the DIMBOA metabolic 3 pathway are located on the short arm of chromosome 4, and QTLs involved in maize resistance to leaf-feeding by 4 corn borers have been localized to that region. However, the low resolution of QTL linkage mapping does not allow 5 convincing proof that genetic variation at bx loci was responsible for the variability for resistance. This study 6 addressed the following objectives: to determine the QTLs involved in DIMBOA synthesis across genetically 7 divergent maize inbreds using eight RIL families from the NAM population, to check the stability of QTLs for 8 DIMBOA content across years by evaluating two of those RIL families in two years, and to test the involvement of 9 bx1 by performing association mapping with a panel of 281 diverse inbred lines. QTLs were stable across different 10 environments. A genetic model including eight markers explained approximately 34% of phenotypic variability 11 across eight RIL families and the position of the largest QTL co-localizes with the majority of structural genes of the 12 DIMBOA pathway. Candidate association analysis determined that sequence polymorphisms at bx1 greatly affects 13 variation of DIMBOA content in a diverse panel of maize inbreds, but the specific causal polymorphism or 14 polymorphisms responsible for the QTL detected in the region 4.01 were not identified. This result may be because 15 the causal polymorphism(s) were not sequenced, identity is masked by linkage disequilibrium, adjustments for 16 population structure reduce significance of causal polymorphisms or multiple causal polymorphisms affecting bx117 segregate among inbred lines.

19 Key words: DIMBOA, QTL mapping, Association mapping, Nested association mapping, Candidate gene

- 1 Introduction
- 2

29

3 Cyclic hydroxamic acids and their derivatives (benzoxazinoids) are major secondary metabolites among poaceous 4 plants. These compounds have biological activity against plants, insects, fungi, and microorganisms (Niemeyer 5 1988; Pérez and Ormeño-Nuñez 1991) and could also be involved in detoxification of toxic inorganic molecules 6 (Poschenrieder et al. 2005). The main hydroxamic acid in maize (Zea mays L.) is the 2- B-D-glucopyranosyloxy-4-7 hydroxy-7-methoxy-1,4-benzoxazin-3-one (DIMBOA-Glc) (Tipton et al. 1967; Cambier et al. 2000). The 8 benzoxazinoid glucosides are stored in vacuoles as inactive phytoanticipines, while the glucosidases specific for their 9 activation are present in the plastids (Babcock and Esen 1994; Czjzek et al 2000). Upon exogenous or endogenous 10 damage to tissues, the glucoside comes in contact with the glucosidase and the toxic aglucone, DIMBOA (2-4-11 dihydroxy-7-methoxy-1,4-benzoxazin-3-one), is released (Oikawa et al. 1999; von Rad et al. 2001; Park et al. 2004). 12 DIMBOA confers resistance to leaf-feeding by several corn borer species (Klun et al. 1967; Reid et al. 13 1991; Gutiérrez and Castañera 1986; Tseng 1997). DIMBOA decreases in-vivo endoproteinase activity in the larval 14 midgut of the European corn borer (Ostrinia nubilalis) limiting the availability of amino acids and reducing larval 15 growth (Houseman et al. 1989; 1992). DIMBOA has also been reported to affect detoxication and hydrolysis 16 enzymes for Asian corn borer (Ostrinia furnacalis) and Mediterranean stem borer (Sesamia nonagrioides) (Yan et al. 1995; 17 Ortego et al. 1998) larvae. However, DIMBOA had a differential impact on two closely related leaf-feeding 18 generalists, Spodoptera frugiperda and S. exigua (Rostas 2007). Spodoptera frugiperda, which is native in the New World, 19 copes well with DIMBOA in the diet, while DIMBOA is detrimental to S. exigua, an Asian species. Hedin et al. 20 (1993) demonstrated that benzoxazinoids are also toxic factors for Diatraea grandiosella. The protection against insect 21 attack that DIMBOA confers to the plant is restricted to early stages of plant development because DIMBOA 22 concentration decreases with plant age (Morse et al. 1991; Barry et al. 1994; Cambier et al. 2000). Benzoxazinoids 23 are considered as constitutive compounds, but their biosynthesis seems to be increased after insect damage or 24 treatments with methyl jasmonate, a signal molecule of herbivore damage (Gutiérrez et al. 1988; Morse et al. 1991; 25 Huang et al. 2006; Wang et al 2007). Richardson and Bacon (1993) suggested that growth limiting conditions, such 26 as water deficit, also increases the accumulation of benzoxazinoids. Therefore, plant age, insect damage and certain 27 environmental factors can alter DIMBOA levels. 28 In maize the genes involved in DIMBOA's metabolic pathway have been cloned and mapped (Jonczyk et

30 the short arm of chromosome 4, bx7 is also in the short arm of chromosome 4 and bx9 is localized on chromosome

al. 2008). Seven genes (bx1, bx2, bx3, bx4, bx5, bx6, and bx8) map to a genomic region of approximately 6 cM on

31 1. BX1 catalyzes the formation of free indole from indole-3-glycerol phosphate, then the stepwise action of four

1 maize cytochrome P-450-dependent monooxygenases (BX2, BX3, BX4, and BX5) convert free indole to DIBOA 2 (2- 4-dihydroxy-1,4-benzoxazin-3-one) (Frey et al. 1997; Glawischnig et al. 1999). Sequence analysis indicates that 3 BX1 is a modified form of the tryptophan synthase alpha subunit (TSA). bx1 is also evolutionary related to the gene 4 igl which codifies for indole-3-glycerol phosphate lyase, responsible for the formation of volatile indole (Frey et al. 5 2000; Gierl and Frey 2001). bx1 is expressed constitutively in young seedlings, while igl is induced in more advanced 6 stages of plant development and contributes to the blend of odors that attract beneficial parasitoids. Therefore, 7 duplications of the TSA gene involved in the primary metabolism have played an important role in augmenting the 8 plant chemical-defense capacity against insect attack.

9 The next step in the metabolic pathway is the conversion of DIBOA to DIBOA-glc by the action of
10 specific gluocosyltransferases. Two gluocosyltransferases are responsible for the glucosylation of DIBOA, BX8 and
11 BX9 (von Rad et al. 2001). The conversion of DIBOA-glc to DIMBOA-glc requires hydroxylation and methylation.
12 BX6 is responsible for the hydroxylation step that converts DIBOA-glc to TRIBOA-glc (2,4,7-trihydroxy-2H-1,413 benzoxazin-3(4H)-one) and this conversion likely takes place in the cytosol (Frey et al. 2003; Jonczyk et al. 2008).
14 Methylation is catalyzed by BX7, rendering DIMBOA-glc.

15 Quantitative trait locus (QTL) analysis has been used to study maize resistance to leaf-feeding by European 16 corn borer and other insect pests (Bohn et al. 2001; Jampatong et al. 2002; Brooks et al. 2005; 2007; Cardinal et al. 17 2006). There is only one report on the involvement of a QTL close to the bx gene cluster in resistance to leaf-18 feeding by a native American lepidopteran species (Bohn et al. 2001). These results could be the consequence of 19 two important facts, DIMBOA may be non toxic to most native species (Rostas 2007) and/or materials used could 20 have low amounts of DIMBOA. On the contrary, all studies to localize QTLs involved in resistance to leaf-feeding 21 by European corn borer have found QTLs close to the region of chromosome 4 where most bx genes reside 22 (Jampatong et al. 2002; Cardinal et al. 2006). However, the low resolution of the QTL linkage mapping approach 23 does not allow convincing proof that genetic variation at bx loci was responsible for the resistance found in those 24 crosses. By contrast, association mapping is a fine mapping approach which enables researchers to look for 25 functional variation in a broader germplasm background (Zhu et al. 2008). Association mapping could be focused 26 on one or few candidate genes or on the scanning of the entire genome. Although the use of whole genome scan 27 association mapping to identify loci with major effect has been successful for some particular traits such as oleic acid 28 content in maize kernels (Beló et al. 2008), the candidate gene approach has been favoured in species with a fast 29 decay of linkage disequilibrium, such as maize. Association mapping studies with candidate genes have been 30 successful to locate polymorphisms in maize genes bt2, sh1, and sh2 associated to kernel composition traits, in ae1 31 and sh1 to amylose levels, in vgt1 and dwarf8 to flowering-time variation and in c2 and whp1 to maysin content in the

1 silks (Wilson et al. 2004; Szalma et al. 2005; Camus-Kulandaivelu et al. 2006; Ducrocq et al. 2008). Recently, nested 2 association mapping (NAM) has been proposed as a powerful genome-wide association analysis tool to dissecting 3 the genetic basis of quantitative traits in species with low linkage disequilibrium (Yu et al. 2008; McMullen et al. 4 2009a; Buckler et al. 2009). NAM has an increased cost-effective power compared to conventional genome-wide 5 association mapping approaches because the highly dense map obtained for the founders of the RIL's populations 6 can be projected to the RILs by using common-parent-specific markers for genotyping founders and progenies. 7 Both linkage mapping and association approaches could be complementary when used to study maize 8 functional variation for DIMBOA content. Firstly, NAM is used to localize QTLs for DIMBOA content across 9 different RIL families. Then, if QTLs for DIMBOA content variation are identified in the proximity of bx genes, 10 the candidate gene approach will be used with bx1 which is the committal step into the DIMBOA pathway and, 11 consequently, it is the prime candidate for affecting total DIMBOA accumulation. Association mapping will also be 12 performed with sequences from genes bx2, bx3, bx4, bx5, and bx8 to check whether significant associations between 13 bx1 polymorphisms and DIMBOA content could be consequence of linkage disequilibrium between bx1 and the 14 other bx genes located in the same contig. bx6 has been mapped near to bx4 (Jonczyk et al. 2008), but 15 AY104457/PCO086194, which matches by BLAST to AF540907 (cDNA sequence for bx6) maps in chromosome 2 16 rather than in 4.01. Therefore, no amplicons could be obtained for bx6 because there is not a reliable genomic 17 sequence for that gene. This study addressed the following objectives: to determine the QTLs involved in DIMBOA 18 synthesis across genetically divergent maize inbreds using eight RIL populations from the NAM, to check the 19 stability of QTLs for DIMBOA content across years by evaluating two of those RIL populations in two years, and 20 to study the involvement of bx1 performing association mapping with a panel of 281 diverse inbreds. 21 22 Material and Methods 23 24 QTLs for DIMBOA across NAM families 25 Plant material 26 27 RIL families derived from B73 × II14H and B73 × CML322 were evaluated in 2007 and 2008 for determining QTL 28 stability. Eight RIL families derived from crosses between the inbred line B73 and inbreds CML52, CML322, 29 IL14H, M37W, MS71, NC350, Oh43, and Tx303 were used to determine the QTLs involved in DIMBOA synthesis 30 across genetically divergent maize inbreds.

1 In summer of 2007 two RIL families of the NAM population, derived from crosses B73 × Il14H and B73 2 × CML322, were evaluated for DIMBOA, DIMBOA-glc, and the sum of the two which we designate as DIMBOA-3 (T) for total DIMBOA. Fifteen kernels per row were planted in 3.6 m rows, 0.9 m aisles, and 0.9 m between rows 4 on May 18 at the Agronomy Research Center near Columbia, MO. An augmented design was used for each RIL 5 family in which both parental lines were used as common testers across blocks of 20 RILs. Therefore, the inbred 6 B73 was also a common tester across RIL families. On June 25, 38 days after planting, two representative plants per 7 row were selected and a 5 cm section of whorl tissue centered at the highest ligule was collected. After discarding 8 the outside leaf the whorl sections from the two plants per row were bulked, lyophilized, ground and maintained at 9 - 20 °C until chemical analyses. 10 In 2008, eight RIL families derived from crosses between the inbred line B73 and inbreds CML52, 11 CML322, IL14H, M37W, MS71, NC350, Oh43, and Tx303 were evaluated for DIMBOA, DIMBOA-glc, and 12 DIMBOA-T. These eight RIL families are all also part of the NAM population (Yu et al. 2008; McMullen et al. 13 2009a) and include the two families evaluated in 2007. These plants were grown at Hinkson Bottoms within 14 Columbia MO. The kernels were planted on June 10 and whorl tissue collected on July 11, 32 days after planting. 15 Planting conditions and tissue handling were as in 2007. 16 In 2008, the day before tissue collection, the number of emerged leaves per plant was recorded on the two 17 plants per plot which were going to be collected. The fifth leaves had previously been marked 22 days after planting 18 to assure a proper leaf count. 19 20 Chemical analyses 21 22 Chemical determinations of the amount of DIMBOA and DIMBOA-Glc molecules were performed using high 23 performance liquid chromatography (HPLC) using a modification of the procedure of Nakagawa et al. (1995). 24 Purified DIMBOA was a gift from Dr. Monika Frey, Technische Universität München, Freising, Germany. 25 DIMBOA-Glc was isolated from corn leaves and identified by its enzyme hydrolysis products. All other reagents 26 were ACS grade or better and purchased from Thermo-Fisher (St. Louis, MO). Since a DIMBOA-Glc standard was 27 not commercially available, DIMBOA-Glc concentration in samples was calculated based on DIMBOA standards 28 and adjusted for differences in molecular weights. 29 One hundred mg of freeze-dried ground whorl tissue was weighed into screw capped 15 mL polypropylene 30 Falcon tubes and 5 mL of HPLC grade methanol and 50 uL of acetic acid were added to each tube. The tubes were 31 vortexed and placed in a sonicator waterbath for 60 minutes at 60° C. The supernatant (0.5 mL) was combined with

1 0.5 mL distilled water in a microcentrifuge tube, vortexed, and centrifuged for 5 min at 13,000 rpm. The

2 supernatants were transferred into auto-sample vials for analysis by HPLC. The HPLC system consisted of a Hitachi

- 3 Model L-7100 pump with a Hitachi Model L-7400 UV detector (280 nm), Hitachi Model L-7200 autosampler with
- 4 Hitachi D-7000 data acquisition interface and ConcertChrom software on a microcomputer. The column was a 100
- 5 x 4.6 mm reversed-phase Luna 3 μm C18 BDS analytical column (Phenomenex) fitted with a C₁₈ ODS
- 6 SecurityGuard 4.0 x 3.0 mm guard column (Phenomenex) with a mobile phase consisting of metahnol:1% acetic
- 7 acid in water (20:80) run at a flow rate of 1 mL min.
- 8

9 Statistical analyses

10 To check the stability and precision of QTLs detected for DIMBOA content, linkage mapping was done

11 independently for each of the RIL families derived from B73 × CML322 and B73 × IL14H in each year (2007 and

12 2008) and across years. Original linkage maps for each population had more than 700 SNP markers

13 (www.panzea.org); but QTL analyses were performed using linkage maps with an average distance between loci of

14 about 10 cM, yielding a final set of 183 and 178 markers for the 185 and 194 RILs obtained from crosses B73 \times

15 CML322 and B73 × II14H, respectively. QTL Cartographer (Basten et al. 2005) was used for cofactor selection

- 16 using a *p*-value for the partial F statistic of 0.01. A LOD threshold of 3.0 was chosen for declaring the putative
- 17 QTL significant using composite interval mapping. The LOD of 3.00 is slightly above the score value obtained by
- 18 the permutation test method (Churchill and Doerge, 1994) yielding an experiment wise error rate of 25%.

19 PLABQTL (Utz and Melchinger 2003) was used to obtain a final simultaneous fit using as covariates those loci

20 detected by QTL Cartographer. In addition, all putative QTLs were examined for QTL × environment interaction.

- 21 The proportion of phenotypic variance explained by all QTLs was determined by the adjusted coefficient of
- 22 determination of regression (R^2_{adj}) fitting a model including all detected QTLs. The proportion of genotypic
- 23 variance explained by all QTL for one trait (p) was calculated as p = (genetic variance explained by QTL effects)
- 24 genetic variance) x 100.

Fivefold cross validation (CV/G) of QTLs was performed following the procedures described by Utz et al. (2000). The whole data set was randomly split into k=5 data subsets. Four of these subsets were combined to form the estimation set (ES) and the remaining subset formed the test set (TS) in which predictions derived from ES were tested for their validity by correlating predicted and observed data. We used 1000 replicate CV/G runs. Estimates of medians and percentiles and frequency of QTL detection in ES and TS were calculated over all replicated CV/G

30 runs. The PLABQTL (Utz and Melchinger 2003) software package was used for all calculations.

1	To assess the allelic effects of QTLs shared across families, QTL analyses for DIMBOA-(T) content were
2	made across the eight NAM RIL families (1524 RILs) from 2008 using a multiple regression approach with 1106
3	loci (Buckler et al. 2009). The NAM map used can be found at <u>www.panzea.org</u> . The PROC GLMSELECT
4	procedure of SAS (SAS, 2000) was used to choose co-factors using a probability level of 0.00001 for entering and
5	deleting factors (Buckler et al. 2009). Regression analysis was performed with those cofactors and the best fit model
6	for DIMBOA-(T) content was obtained by using the PROC GLM procedure of SAS.
7	
8	Diversity analysis of the bx candidate genes
9	
10	Two hundred and eighty one genetically diverse inbreds were evaluated in 2008 (see list at
11	http://www.panzea.org/lit/Basic281Inbreds_20081210.xls). The experimental design was a complete random
12	block design with two replications. The experimental plot was the same as for RIL evaluations. Thirty-five days
13	after planting, five cm of whorl tissue were collected from two plants per plot, bulked, lyophilized, ground and
14	maintained at -20 °C until performing chemical analyses.
15	The DNA was extracted using standard protocols (Saghai-Maroof et al. 1984) with minor modifications.
16	The genomic DNA sequence X76713 (<u>http://www.ncbi.nlm.nih.gov</u>), corresponding to <i>bx1</i> was BLASTed against
17	the B73 sequence database (http://www.maizesequence.org/index.html) and an evidence-gene sequence,
18	AC200309.3:82911-85155bp (GRMZM2G085381), was identified. PCR primers to amplify four amplicons of 500-
19	800 bp (Supplemental Table 1) covering the evidence-gene from 36 bp downstream of the 5' end to 148 bp
20	upstream of 3' end were designed using the Primer3 program (http://frodo.wi.mit.edu/). Similarly, evidence-gene
21	sequences for <i>bx1</i> -adjacent <i>bx</i> genes (<i>bx2</i> , AC200309.3:87362-89517 (GRMZM2G085661); <i>bx3</i> , AC193441.3:7574-
22	10352 (GRMZM2G167549); <i>bx4</i> , AC213878.3:11418-114239 (GRMZM2G172491); <i>bx5</i> , AC213878.3:49953-52529
23	(GRMZM2G063756) and <i>bx8</i> , AC200309.3:36796-38707 (GRMZM2G085054)) were identified and PCR primer
24	pairs were designed to generate amplicons for each sequence. Touchdown PCR was performed using Promega or
25	Phire Taq in a DNA Engine Tetrad thermocycler (MJ Research). The PCR program consisted of one cycle of 1 min
26	at 94°C, 1 min at 65°C, and 1 min 30 sec at 72°C; the same cycle was repeated with 1°C decrement in annealing
27	temperature per cycle until annealing temperature is 55°C; then, 34 cycles of 1 min at 94°C, 1 min at 55°C, and 1
28	min 30 sec at 72°C are performed. Following PCR amplification, unincorporated primers and deoxynucleotide
29	triphosphates were removed by ethanol precipitation prior to sequencing. For each amplicon, the PCR products
30	were sequenced with forward and reverse primers using BigDye terminator version 3.1 terminator cycle sequencing
31	kit (Applied Biosystems) and analyzed on an ABI 3700 sequencer (Applied Biosystems).

1	Base calling, quality assessment, and trimming of trace files were conducted with PHRED (Ewing and
2	Green, 1998; Ewing et al., 1998), and sequence assembly was performed by PHRAP. The multiple sequences for
3	each gene were aligned with DNAAlignEditor (Sanchez-Villeda et al. 2008) and edited manually. All sequences are
4	available from GenBank with accessions GF098181-GF099430 and GF100745-GF101806 and association mapping
5	and linkage disequilibrium (LD) analyses were performed using TASSEL version 2.1 (Bradbury et al. 2007).
6	Polymorphisms with low allele frequency (< 5%) were removed. Association analyses were performed by using
7	generalized linear (GLM) and mixed linear (MLM) regression models accounting for population structure (GLM and
8	MLM) and relatedness among individuals (MLM). Population structure was controlled using both the (Q) and
9	kinship (K) matrixes as reported by Flint-García et al. (2005) and Yu et al. (2006), respectively.
10	
11	Results
12	
13	Mapping of QTLs across years
14	
15	Linkage mapping of RIL families derived from $B73 \times CML322$ and $B73 \times IL14H$ for DIMBOA, DIMBOA-Glc,
16	and DIMBOA-(T) content was performed across years (2007 and 2008). The parents of the (B73 \times CML322) RIL
17	family differed for DIMBOA, DIMBOA-Glc, and DIMBOA-(T) content in 2007, but not in 2008 (Table 1).
18	Similarly, the parents of the (B73 \times II14H) RIL family differed for the three fractions in 2007, but only for
19	DIMBOA content in 2008. Heritabilities for DIMBOA, DIMBOA-Glc, and DIMBOA-(T) contents were high in
20	both RIL families (Table 1).
21	QTLs affecting DIMBOA, DIMBOA-Glc and DIMBOA-(T) contents across years were detected in both
22	RIL families (Tables 2 and 3). In general, QTLs detected for DIMBOA-(T) co-localized with QTLs detected for
23	either DIMBOA and/or DIMBOA-Glc. Five QTLs were found for DIMBOA-(T) in the RILs derived from B73 \times
24	CML322 (Table 2). The largest QTL was detected on the short arm of chromosome 4, explaining the 42.5 % of the
25	phenotypic variance for DIMBOA-(T). The favourable allele was supplied by the inbred B73. Two other major
26	QTLs on chromosomes 1 and 8, explained 18.4 and 13.7 % of the phenotypic variability, respectively. Favourable
27	alleles for these two QTL were also contributed by B73. Favourable alleles for minor QTLs situated in
28	chromosomes 3 and 7 were inherited from the parental inbred with low DIMBOA-(T) content, CML322. The final
29	model explained 55.3% of genetic variance. In cross validation analysis, the median QTL effect for the QTL on
30	chromosome 4 calculated from CV/G was similar to the value calculated from the full data set. However, for the
31	other QTLs, the ratio between CV/G and full data set varied from 0.80 to 2.40. QTLs located on chromosomes 1,

3, 4, 7, and 8 were detected in 97.2%, 79.0%, 100.0%, 82.1%, and 62.0% of all cross validations runs, and explained
 almost 50% of the genetic variance.

3 Three QTLs were found for DIMBOA-(T) content in the RIL family obtained from $B73 \times II14H$ (Table 4 3). The most important QTL was again localized at the beginning of chromosome 4 and explained approximately 5 the 9.5% of phenotypic variability. The favourable allele for this QTL was derived from the inbred Il14H. The two 6 other QTLs were located in chromosomes 1 and 6. B73 supplied the favourable allele for the QTL in chromosome 7 1 and Il14H for the QTL in chromosome 6. In this particular RIL family, QTL × environment effects were very 8 important, and the QTL detected only explained 5.4% of genetic variability. Again, the median QTL effect for the 9 QTL in chromosome 4 calculated from CV/G runs approximated the value calculated from the full data set. The 10 ratio between CV/G and full data set for QTLs in chromosomes 1 and 6 varied from 1.20 to 1.40. QTLs in 11 chromosomes 4 and 6 were detected in 76.5 and 80.4% of CV/G runs, but the QTL on chromosome 1 was only 12 detected in 26.7% of CV/G runs. The analysis of two years data for two RIL families indicated that shared QTLs 13 are present on chromosomes 1 and 4. The results also suggest that an allelic series exists for the chromosome 4 14 QTL with II14H > B73 > CML322. 15 16 Mapping of QTLs across RIL families 17 18 To further test for shared QTL and the presence of allelic series for DIMBOA QTL eight RIL families were 19 evaluated in 2008 (Table 4). Mean values for each genotype were not adjusted by the block effect because there 20 were not significant differences among blocks for DIMBOA-(T) content in any experiment (data not shown). 21 Differences for DIMBOA-(T) were significant between the parents of the RILs derived from B73 × CML52, B73 × 22 MS71, and B73 × NC350. The mean of the DIMBOA-(T) amounts of RILs within a family, varied from 23 approximately the value of the high parent, intermediate between both parents or similar to the parent with the low 24 amount (Supplemental Table 2). The average of the RIL family derived from B73 × CML322 for DIMBOA-(T) 25 content was significantly lower than the mean of either parent. 26 From the GLMSELECT analysis across the eight families, QTLs with significant effects for DIMBOA-(T) 27 content were found on chromosomes 1, 2, 4, 5, 6, and 8 (Table 4). After accounting for the variability explained by 28 differences among families (family as a term in the model), the closest marker to the major QTL detected in 29 chromosome 4 explained more than 15% of phenotypic variation across the eight families. Each of the closest 30 markers to QTLs in chromosomes 2 and 5 explained more than 3% of phenotypic variability and each of the

- 1 remaining markers explained from 1.6 to 2.8% of the phenotypic variability across all families. The final model
- 2 explained approximately 34% of intra-population phenotypic variability across the eight families.
- 3 For DIMBOA-(T), significant effects of markers PZA03189 (chromosome 1, at bin 1.04), PHM1184 4 (chromosome 4, at bin 4.01), PZA01527 (chromosome 6, at bin 6.01), and PZA00473 (chromosome 6, at bin 6.05), 5 displayed both positive (favourable allele came from the non-B73 parent) or negative (favourable allele came from 6 B73) effects, depending on the specific RIL family (Table 4). Significant effects of the markers PZA00635 7 (chromosome 2, at bin 2.04) and PZA02746 (chromosome 8, at bin 8.06) were always negative, while significant 8 additive effects of markers PZA02002 (chromosome 4, at bin 4.04) and PZA00980 (chromosome 5, at bin 5.07) 9 were always positive. The effects of the marker PHM1184.26 were significant in seven out of the eight RIL families, 10 PZA03189.4 in six, PZA00473 and PZA02746 in five, PZA00635 in four, PZA00980 and PZA01527 in three, and 11 PZA02002 in two. The additive genetic effect of the marker PHM1184 was more than 1000 ppm in two families, 12 while genetic effects of markers PZA03189 (chromosome 1, at bin 1.04), PZA00635 (chromosome 2, at bin 2.04), 13 PZA00980 (chromosome 5, at bin 5.07) reached 600 ppm in specific families (Table 4). 14 As DIMBOA content declines with plant age, faster growing plants may have a lower DIMBOA content 15 by dilution of DIMBOA with greater plant mass. To determine if plant growth is a confounding factor for any of 16 the QTL reported above we determined the correlation of leaf number with DIMBOA levels and mapped QTL for 17 leaf number present at time of tissue collection. The number of leaves was significantly and negatively correlated 18 with DIMBOA-(T) content across populations (r = -0.19, p < 0.0001), and within the RIL families derived from the 19 crosses $B73 \times CML52$, $B73 \times M37W$, $B73 \times MS71$, and $B73 \times Oh43$, although correlation coefficients were low 20 (Supplemental Table 2).
- As a significant relationship was found between DIMBOA-(T) content and number of leaves per plant,
 QTL analyses for leaf number were performed. Three minor QTLs were detected explaining approximately the 9%
 of variability for number of leaves. Those markers were PZA0300.2 located in chromosome 1 at bin 1.05,
- 24 PZA00485.2 located in chromosome 2 at bin 2.05, and PZB02044.1 in chromosome 3 at bin 3.05.
- 25

26 Diversity analysis of the *bx* candidate genes

27

28 We identified 45 INDELs and 44 SNPs across the four amplicons in *bx1*, 6 INDELs and 11 SNPs in one amplicon

29 for *bx2*, 3 INDELs and 19 SNPs in one amplicon for *bx3*, 3 INDELS and 1 SNP in one amplicon for *bx4*, 10

- 30 INDELS and 35 SNPs across the three amplicons in *bx5*, and no polymorphisms of greater than 5% frequency for
- 31 bx8. Twenty-eight polymorphisms across bx1 and one polymorphism in bx2 were significantly associated (p < 1

1 0.001) with DIMBOA-(T) content in analysis using both Q + K matrix (Yu et al. 2006) to adjust for population 2 structure (Fig. 1). The most strongly associated polymorphism was an SNP (A/G) at 620 bp in amplicon X76713.5 3 $(X76713.5_620)$ of the gene bx1, Genetic variation at that polymorphism explained 4% of the phenotypic variation 4 not accounted for by population structure using MLM. Considering all polymorphisms in bx1 significantly 5 associated to DIMBOA-(T), more than 50 different haplotypes were identified for bx1 (supplemental table 3). 6 Therefore, in order to fit a multilocus model, we performed three-way ANOVA analyses including as sources of 7 variation: groups (Stiff Stalk, Non Stiff Stalk and Tropical - equivalent to Q), the X76713.5_620 polymorphism (as 8 being the most significantly associated to DIMBOA-(T) content) and then test all other significant polymorphism. 9 The model including the polymorphisms in exons 5 and 6 at sites X76713.5_620 and bx1_1.9_143 (3 bp INDEL at 10 143 bp in amplicon bx1_1.9), respectively, and variation among groups was the only model in which both 11 polymorphisms remained significant. This model explained 12% of variation not accounted for by population 12 structure and 27% of total variability among inbreds. Average DIMBOA-(T) content for each haplotype was 1986 13 \pm 536 ppm for the A SNP (X76713.5_620) - 3 bp insertion (bx1_1.9_143), 2890 \pm 239 ppm for G SNP 14 $(X76713.5_620) - 3$ bp insertion (bx1_1.9_143), 1403 ± 283 ppm for A SNP (X76713.5_620) - 3 bp deletion 15 $(bx1_{1.9}_{143})$, and 2128 ± 317 ppm for G SNP (X76713.5_620)- 3 bp deletion $(bx1_{1.9}_{143})$. Among the 16 parental inbreds of the RILs families, B73, M37W, MS71, Oh43, and Tx303 carried the genetic variants at those 17 points favourable for DIMBOA-(T) accumulation (G at X76713.5_620 and 3 bp insertion at bx1_1.9_143); while 18 CML322, CML52, IL14H, and NC350 carried the unfavourable ones (A at X76713.5_620 and 3 bp deletion at 19 bx1_1.9_143). 20 In general, the level of linkage disequilibrium (LD) within the bx1 gene rapidly decayed with distance (Fig. 21 2). However, LD coefficients (r²) between the significant polymorphisms included in the ANOVA model, 22 $X76713.5_{620}$ or bx1_1.9-143, and other polymorphisms were > 0.2 up to a distance between polymorphisms of 23 approximately 600 bp (Fig. 1). All significant polymorphisms were in significant LD (p < 0.01) with X76713.5_620 24 and/or bx1_1.9-143, except two polymorphisms located at the beginning of bx1 and the INDEL located at 25 X76713.5_40 (data not shown). The result that the initially significant polymorphism in bx2 did not remained 26 significant in the multilocus model indicates that the initial significance is due to residual LD with the 27 polymorphisms in bx1.

- 1 Discussion
- 2

3

4 parents were significant for most traits. Therefore, QTLs with appreciable effect on DIMBOA content are expected 5 to be found. In the B73 × CML322 family 47.1 to 63.4 % of genetic variability for DIMBOA, DIMBOA-Glc and 6 DIMBOA-(T) among RILs could be explained by the detected QTLs. This is in contrast to only 4.5 to 21.2 % of 7 variability for RILs derived from B73 × II14H family. The B73 × CML322 family contrasts a moderate DIMBOA 8 parent with a low DIMBOA parent while the B73 × II14H family contrasts a moderate DIMBOA parent with a 9 slightly higher DIMBOA parent. These results suggest that undetected QTLs with small effects could be 10 responsible for unexplained differences for DIMBOA, DIMBOA-Glc, and DIMBOA-(T) contents in some 11 backgrounds such as the B73 × Il14H family. Therefore, larger population sizes may be necessary to increase the 12 detection power and uncover where those genes lie. The NAM population could provide that increase in power if 13 those genes with minor effect are segregating in multiple RIL families. 14 The use of two environments for evaluations and cross validation allowed tests of the consistency of the 15 results (Bohn et al. 2001). Cross validations provide more reliable estimates of R^2_{adi} and \hat{a} by avoiding bias causing 16 model selection (Beavis 1998). Most QTLs found in both populations were reliable because the additive effects 17 computed with the CV/G data were significant and similar to those computed with the full data set. In addition, 18 most QTLs were found in more than 75% of CV/G runs. Therefore, the precision of QTL positions is adequate to 19 use markers close to them in MAS-assisted selection (Utz et al. 2000). 20 As QTLs for DIMBOA-(T) were, in general, the sum of QTLs detected for DIMBOA and DIMBOA-21 Glc, we will focus discussion on DIMBOA-(T) content. Although the additive effects for the QTL were higher 22 among RILs derived from $B73 \times CML322$ and accounted for a much higher percentage of genetic variability, two 23 QTLs, located in chromosomes 1 and 4, were involved in the DIMBOA pathway in both populations. The QTL on 24 chromosome 4 was located in both populations on the short arm of chromosome 4 where the bx1, bx2, bx3, bx4, 25 bx5, bx6, and bx8 genes are located (http://www.maizesequence.org/index.html). Therefore, polymorphisms for 26 one or more of these structural genes of the DIMBOA pathway (Jonczyk et al. 2008) could be responsible for most 27 of the variance among (B73 × CML322) RILs and for almost 10 % of phenotypic variability among (B73 × II14H) 28 RILs. Bohn et al. (2001), Jampatong et al. (2002), and Cardinal et al. (2006) have reported QTLs for leaf-feeding 29 damage by lepidopterous species in the same genomic area, on chomosome 4 (bin 4.01). No significant QTLs were 30 found in the proximity of genes bx7 (contig 160) and bx9 (contig 37). In addition to the region of structural genes, 31 the involvement of other genomic regions (bins 1.03-1.04, 3.08, 6.01, 7.02, and 8.06) may reveal the position of

Heritabilities for DIMBOA levels were high in both RIL families tested in two years and differences between inbred

unknown regulatory genes (McMullen et al. 2009b). Regions in chromosomes 1 (1.04), 3 (3.08), 6 (6.01), and 7
 (7.02), and 8 (8.06) had already been identified as involved in resistance to leaf feeding by *Diatraea grandiosella* and
 Ostrinia nubilalis (Bohn et al. 1997; Groh et al. 1998; Jampatong et al. 2002; Brooks et al. 2005; 2007; Cardinal et al.
 2006). Therefore, there is a convergence of loci for DIMBOA levels with loci detected in insect resistance QTL
 experiments.

6 To extend the results from the two families of RIL to a broader range of germplasm, to determine the 7 degree of shared QTL across parents, and to test for allelic series at QTL for DIMBOA, eight families from the 8 NAM population were evaluated in 2008. The values for DIMBOA-(T) of each RIL family and its inbred parents 9 only differed for crosses B73 × CML322, B73 × CML52, M73 × MS71, and B73 × NC350. In general, the mean of 10 RIL families did not approximate the mid parent value for DIMBOA-(T) content, but exhibited DIMBOA levels 11 closer to the high or low parent or even showed less amount for DIMBOA-(T) content than both parents. These 12 data suggest that epistatic effects may play an important role in the inheritance of DIMBOA-(T) content. However, 13 a model including only additive effects explained approximately 34 % of phenotypic variability within RIL families 14 for DIMBOA-(T). As in the individual family analysis, the largest QTL in the across family analysis was located on 15 chromosome 4. The position of the significant marker, PHM1184, is on BAC contig 155, and co-localises with the 16 majority of structural genes of the DIMBOA pathway (www.maizesequence.org). In addition, seven other genomic 17 regions (located in chromosomes 1, 2, 4, 5, 6, and 8) explained as much variability as likely explained by 18 polymorphisms at structural genes. Previous supporting evidence of the potential involvement of some of these 19 genomic regions in DIMBOA synthesis comes from studies of QTLs for resistance to the first generation of Ostrinia 20 nubilalis (Jampatong et al. 2002; Cardinal et al. 2006) since resistance to the first generation of this insect in temperate 21 material is largely associated to midwhorl DIMBOA levels (Barry et al. 1994). Agreeing with those previous studies, 22 we have found QTLs for DIMBOA-(T) at bins 4.01, 4.04, 6.01, and 8.06. However, marker polymorphisms at bins 23 1.04, 2.04, 5.07, and 6.05 were not previously associated with phenotypic variation for resistance to the first 24 generation of Ostrinia nubilalis. The lack of prior report of these QTL for first generation resistance could be due to 25 either a low effect level of these loci or genetic heterogeneity as positive alleles at these loci only occurred in a subset 26 of the RIL families. All QTLs for DIMBOA content, except those located at 2.04, 4.04 and 5.07, were in regions 27 where QTL for resistance to leaf-feeding by Diatraea grandiosella and D. saccharalis were previously detected (Groh et 28 al. 1998, Khairallah et al. 1998; Bohn et al. 2001; Brooks et al. 2005; 2007). 29 Most QTLs detected when computing QTL analyses of individual RIL families were also included in the fit 30 model for the eight families, except those QTLs that explained less than 10% of variability within unique RIL

31 families or were located on the same chromosome as another detected QTL (data not shown). Therefore, the

14

1 procedure of searching for QTLs across individual RILs families could miss those QTLs with significant effects in 2 unique families, mostly when they are located in close proximity of other QTLs with significant effects across 3 populations. Yu et al. (2008) estimated the average power of NAM under different trait complexity schemes using 4 different number of RILs and determined that the average power could be approximately 0.6 when the number of 5 QTLs was 20, $h^2 = 0.7$, and the number of RILs = 1500. Consequently, it is not surprising that QTLs with low or 6 moderate additive effects in unique populations are not identified using NAM analysis, but the decrease in power of 7 detection when performing NAM analysis compared to conventional linkage analysis seemed to be low. Moreover, 8 due to the increased resolution, additive effects for markers detected by the NAM approach were highly significant 9 (p < 0.001) for particular RIL families in which no QTLs were found near to the marker using conventional linkage 10 mapping (data not shown). 11 The tropical lines used in this study, CML322, CML52, and NC350, supplied alleles for the QTL at 4.01 12 with significant negative effects for DIMBOA-(T) concentration. This would explain why most studies conducted 13 to locate QTLs for resistance to leaf feeding by native American lepidopterous insects among tropical and 14 subtropical inbreds did not report QTLs close to the bx region (Bohn et al. 2001; Brooks et al. 2005; 2007). This 15 result also agrees with the concept that different mechanisms from DIMBOA antibiosis are present in resistant 16 tropical maize. Bohn et al. (2001) found QTLs for resistance to leaf feeding by Diatraea grandiosella at chromosome 17 positions 4.01 and 6.01, where QTLs for DIMBOA-(T) have been located, but the favourable alleles for resistance 18 to the pest came from the susceptible tropical inbred (Ki3), and not from the resistance source. 19 The additive effects of the marker PZA00635 (at bin position 2.04) were significant in four RIL families, 20 this maker is located in contig 80, close to the position of a gene that codes for a specific glucosidase (β -glu2 in 21 contig 84). It is unclear how variability for a specific glucosidase for DIMBOA-Glc, whose activity renders 22 DIMBOA from DIMBOA-Glc (Morant et al. 2008), could affect variability for DIMBOA-(T) content. 23 For markers in chromosomes 1 at bin 1.04, 4 at bin 4.01, and 6 at bins 6.01 and 6.05, there were at least 24 three different alleles because non-B73 parents supplied alleles with increased and decreased additive effects for 25 DIMBOA-(T) content compared to B73. Therefore, although no more than two alleles were segregating in each 26 RIL family, allowing a high detection power, the additive effects of more than two allelic variants per loci could be 27 simultaneously estimated using the multiple family approach of NAM. 28 Previous studies showed that DIMBOA concentration decreases with plant age (Morse et al. 1991; Barry et 29 al. 1994; Cambier et al. 2000). We demonstrated a significant, negative association between DIMBOA-(T) content 30 and plant growth measured as number of leaves per plant. Therefore we reasoned that factors regulating growth

31 could also appear as QTL for DIMBOA synthesis. Three QTLs involved in differences for number of leaves were

15

1 found and markers linked to those QTLs explained approximately the 9% of phenotypic variation for number of 2 leaves, but none of these markers were co-localized to markers associated with variation for DIMBOA-(T) content. 3 Therefore, none of the QTL identified for DIMBOA synthesis are genetically correlated to growth loci. The 4 apparent negative correlation of leaf number with DIMBOA-(T) must involve small genetic effects not detected as 5

6 As position of the largest QTL co-localizes with the majority of structural genes of the DIMBOA pathway, 7 and bx1 is the committal step into the DIMBOA pathway, it is the prime candidate for affecting total DIMBOA 8 accumulation. Therefore association analysis was used to determine if genetic variation at bx1 affects variation of 9 DIMBOA-(T) content. General (GLM) and Mixed Linear Models (MLM) revealed associations between variability 10 for DIMBOA-(T) content and sequence polymorphisms at bx1 locus. After adjusting for population structure, a 11 model including two polymorphisms in bx1 explained 12% of phenotypic variation in a population of 282 diverse 12 lines. This is close to the 15% effect predicted by the GLMSELECT analysis for the chromosome 4 QTL across 13 eight families of RILs. However, these polymorphisms could not explain genetic effects for DIMBOA-(T) content 14 of the closest marker (PHM1184) to the major QTL detected in chromosome 4. For example, inbreds CML322 and 15 IL14H carried the same genetic variants at both polymorphisms, but among RILs families obtained from crosses to 16 B73, the allele at PHM1184 from CML322 had a negative additive effect for DIMBOA-(T) content, while the allele 17 from IL14H had a positive effect. Therefore, the high percentage of variation explained by the model including the 18 two polymorphisms at exons 5 and 6 in bx1 and their significant LD with other significantly associated 19 polymorphisms in bx1 and bx2 suggests that genetic variation for bx1 is particularly important for determining 20 DIMBOA content in a diverse panel of maize inbred lines. The rapid decay of LD and the fact that no 21 polymorphisms in bx^2 were significant in the presence of a significant bx^1 polymorphism suggest that the main 22 causal polymorphisms are within or near the bx1 gene and alter DIMBOA content by affecting BX1 level. 23 However, the specific causal polymorphism or polymorphisms responsible for the QTL detected in the region 4.01 24 were not identified, either because those polymorphisms were not sequenced (bx1 was not entirely sequenced), 25 causal polymorphism is outside the coding region, identity is masked by linkage disequilibrium, adjustments for 26 population structure reduce significance of causal polymorphisms or multiple causal polymorphisms affecting bx1 27 segregate among inbred lines. In characterizing QTL for flowering time in maize Buckler et al. (2009) demonstrated 28 that common QTL with uncommon, multiple alleles is the norm. It may be that bx1 from Il14H has a distinct 29 causal polymorphism increasing DIMBOA levels from the causal polymorphisms in LD with the significant SNP 30 detected in this study.

31

significant QTL.

Table 4. Position, and effects of markers identified as significant for DIMBOA-(T) (ppm) content in the GLM model. Significant effects are in bold.

¹Chromosome where the QTL is located. ² Position of the marker in cM. ³Mean additive effect of the marker in each RIL family with its corresponding probability level, positive effects negative effects mean that the allele for higher amount came from B73 ⁴ Proportion of intra-population phenotypic variance explained. ⁵ The

QTL identified by individual analysis of the specific RIL family was less than 5 cM apart from the marker identified as associated to DIMBOA-(I) content across populations.

Supplemental table 3 . Genotypes for 177 inbred lines at each SNP and INDEL in *bx1* associated significantly to DIMBOA contentAmpliconbx1_1.10X76713.2

:' is a missing data and '-' one base deletion at the SNP

Figures

Fig. 1 Association of DNA polymorphisms with DIMBOA-(T) content across genomic portions of genes bx1 (82911-85155 bp) and bx2 (87362-89517 bp). The positions correspond to BAC sequence AC200309.3. Blue diamonds indicate association with DIMBOA content. Level of statistical association for each SNP and INDEL is expressed as -Log 10[P]. Pink squares indicate $r^2 LD$ scores for all marker pairs involving X76713.5_620 and yellow triangles $r^2 LD$ scores for all marker pairs involving bx1_1.9_143.

Fig. 2 Linkage disequilibrium (LD) across *bx1* and part of *bx2* genes.
