Abstract. A series of 75 guanidine and 2-aminoimidazoline analogue molecules were assayed in vitro against *Trypanosoma brucei rhodesiense* STIB900 and *Plasmodium falciparum* K1. The dicationic diphenyl compounds exhibited the best activities with IC₅₀ values against *T. b. rhodesiense* and *P. falciparum* in the nanomolar range. Five compounds (**7b**, **9a**, **9b**, **10b**, and **14b**) cured 100% of treated mice upon ip administration at 20mg/kg in the difficult to cure *T. b. rhodesiense* STIB900 mouse model. Overall, the compounds that bear the 2-aminoimidazoline cations benefit from better safety profiles than the guanidine counterparts. The observation of a correlation between DNA binding affinity at AT-sites and trypanocidal activity for three series of compounds supported the view of a mechanism of antitrypanosomal action due in part to the formation of a DNA complex. No correlation between antiplasmodial activity and in vitro inhibition of ferriprotoporphyrin IX biomineralisation was observed, suggesting that additional mechanism of action (MOA) is likely to be involved.

Key words: chemotherapy; plasmodium; trypanosome; guanidine; imidazoline; malaria; sleeping sickness; DNA minor groove binding; hemozoin.

Introduction

Infectious diseases caused by protozoan parasites are responsible for great morbidity and mortality mainly in the least developed countries. Despite the lack of significant research investment on tropical diseases, rich countries recently started to pay attention to malaria because this disease also represents a potential threat for the developed world. Another tropical disease, human African trypanosomiasis (HAT or sleeping sickness) is only present in sub-Saharan Africa and affects between 50.000 and 70.000 people.¹ HAT belongs to the most neglected diseases as defined by a World Health Organization/Industry working group.²

Drugs available for HAT are obsolete and present unacceptable adverse effects, as well as increasing treatment failures due to emergence of drug resistance or other reasons.^{3–5} On the other hand, the chemotherapy of malaria is principally impaired by the appearance of drug resistant strains of *Plasmodium* spp.. Hence, chloroquine which was the most common antimalarial drug for decades is now practically ineffective and emergence of resistance to other drugs such as mefloquine, halofantrine or artemisinin is beginning to appear.⁶ For those reasons, WHO now recommends the use of antimalarial drug combinations (e.g., artesunate/mefloquine, artesunate/amodiaquine) in order to delay the development of resistant strains.⁵ Thus, the discovery of new safe and efficient antiprotozoal agents to treat HAT and malaria is a priority in international health.

Recent findings by our group have shown that bisguanidine and especially bis(2aminoimidazoline)diphenyl compounds displayed potent antitrypanosomal activity in vitro and vivo against *T. b. rhodesiense*, the causative agent of acute HAT.^{7, 8} These studies revealed that compounds bearing 2-aminoimidazoline cations (scaffold A, Chart 1) had higher selectivity for the parasite and similar activities with respect to their

3

guanidine counterparts. In addition, a correlation between antitrypanosomal activity and DNA binding affinity was observed, suggesting a possible mechanism of action for these compounds.⁷ Finally, we showed that this class of compounds (i.e., **1a** and **1b**) entered into trypanosomes via different transporters in addition to P2, indicating that parasites that have lost the P2 transporter in selection of resistance to other drugs will not show cross-resistance to this class of compounds. Encouraged by these promising results, another series of 16 dicationic analogues (**3**–**4**, **7**–**11**, **13b** and **14**, Table 1) was evaluated against *T. b. rhodesiense* and their DNA binding affinity at AT-rich sites was estimated by ΔT_m measurements with a nonalternating AT sequence DNA polymer.⁹

Others have described excellent antiplasmodial activity of related aromatic dicationic structures such as pentamidine or DB75.^{10–13} For example, DB289, the neutral prodrug of DB75, has been used to treat uncomplicated *P. vivax* and *P. falciparum* malaria.¹⁴ Stead *et al.* demonstrated that uptake of pentamidine into infected erythrocytes proceeds via a route similar to the new permeability pathway (NPP). In addition, it has been proposed that these diamidines share a common MOA with chloroquine by binding to ferriprotoporphyrin IX and inhibiting the formation of hemozoin.¹⁵ These findings prompted us to test the antiplasmodial potential of our dicationic diphenyl compounds (Chart 1, scaffold A).⁹ The capacity of the compounds to inhibit the formation of hemozoin as possible mechanism of antiplasmodial activity was also evaluated in vitro with the ferriprotoporphyrin IX binding inhibition test (FBIT).¹⁶

Moreover, in order to extend our understanding of the SAR of this class of antiprotozoal agents two new series of cationic analogues, namely 2-aminoimidazolinium compounds and their guanidinium counterparts (Chart 1: scaffolds B and C) were selected for in vitro screening on *T. b. rhodesiense* and *P. falciparum*. As can be shown in Chart 1, the three analogous series are strictly structurally related one

to each other: scaffold A represent the "full" dicationic diphenyl model compound. Scaffold B is analogous to A but devoid of one cationic group whereas scaffold C has "lost" one cationic moiety and one phenyl ring. With these series in hand, we intend to demonstrate the significance of each part of the molecule for the overall activity of the dicationic diphenyl compounds and gain insight into the SAR of this series of antiprotozoal compounds.

Finally, to check whether the activity was maintained in vivo, the most active and selective compounds in vitro were assayed in an acute HAT mouse model (*T. b. rhodesiense* STIB900) or rodent malaria model (*P. berghei* GFP ANKA). Several lead compounds with excellent in vivo activity emerged from this screening.

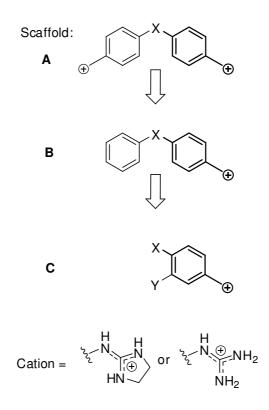

Chart 1. General structures of the compounds studied highlighting the skeleton common to the different scaffolds.

Results

Chemistry

Many of the compounds presented here were previously synthesised by us for other purposes. The synthesis of 1a-e, 2a-c, 5a-f, 6a-e and 12a-b was described earlier.^{8, 17} The synthesis of compounds 3a-b, 4a-b, 15a-b, 17a-b, 18b, 24-26a-b, 29a-b, 31a-b, 33–35a–b and their Boc-protected precursors was described in a recent paper of F. Rodriguez et al.¹⁸ The synthesis of 10a-b, 13b, 14a-b, 16a-b, 27a-b, 28a, 32a-b, 36a-b, 37b and their Boc-protected precurors will be reported elsewhere.¹⁹ The synthesis of 7a-b, 8a, 9a-b, 11a-b, 19-23a-b and 30a-b is described in Schemes 1 and 2. Amongst these derivatives, 7a, 11a-b, 19a-b, 20a-b, 21a-b, 22b, and 23b (in addition to all the Boc-protected precursors) are new, whereas 7b,²⁰ 8a,²¹ 9a,²² 9b,²³ $22a^{24, 25}$ and $23a^{22}$ have been previously described in the literature using different synthetic strategies. Briefly, our synthetic approach to introduce the guanidine and 2aminoimidazoline groups relied on the reaction between primary amines or diamines N,N'-bis(*tert*-butoxycarbonyl)thiourea/HgCl₂/Et₃N²⁶ and or *N*,*N*'-bis(*tert*butoxycarbonyl)imidazoline-2-thione/HgCl₂/Et₃N.¹⁷ affording the Boc-protected guanidines (7d, 9d, 11d, 19d, 20d, 22d, 23d and 30d) and 2-aminoimidazolines (7e, 9e, 11e, 19e, 20e, 22e, 23e, and 30e), respectively. Removal of the Boc protecting groups with TFA followed by anion exchange chromatography afforded the hydrochloride salts of the compounds 7a-b, 8a, 9a-b, 11a-b, 19a-b, 22a-b, 23a-b, and 30a-b. Compounds 20a, 20b, 21a and 21b were studied as their trifluoroacetate salts (Scheme 1). In the case of the thiourea derivatives 8d, 21d and 21e, an alternative strategy was employed to avoid the competitive reaction occurring between the thiourea linker of the starting material (i.e., 8 and 21) and the thiourea guanidine precursors for the $HgCl_2$ catalyst (Scheme 1). Hence, 8d was obtained by condensation of the monomer 8^{18} in an excess of carbon disulfide. Alternatively, the reaction of 8 with one equivalent of phenylisothiocyanate in CH_2Cl_2 afforded the guanidine derivative **21d** (68%). Compounds 20d and 23d could also be synthesized in a similar way by reaction of 8 with phenyl isocyanate or benzovl chloride, respectively. A similar approach was used for the synthesis of the 2-aminoimidazoline analogue 21e starting from 8b. Thus, 1,4phenylenediamine was reacted with one equivalent of *N*,*N*'-bis(*tert*butoxycarbonyl)imidazoline-2-thione/HgCl₂/Et₃N,¹⁷ to afford the monomer **8b**. The crude product 8b was reacted without further purification with 1 equiv. of phenylisothiocyanate, yielding 21e after chromatography on neutral alumina (22% for two steps). Four of the starting material amines (7,²⁷ 11,^{28, 29} 20 and 22) were obtained in a straightforward manner as depicted in Scheme 2.

Biological results

In Vitro Activity. Structure-Activity Relationships.

The results of the in vitro antitrypanosomal and antiplasmodial activity are presented in Tables 1, 2 and 3. In order to gain insights into the mechanism of antiplasmodial and antitrypanosomal activity, the most active compounds (i.e., diphenyldicationic derivatives, scaffold A) were also tested as inhibitors of β -hematin formation¹⁶ and as DNA minor groove binders.³⁰

Antitrypanosomal activity. In general, the presence of two cations (scaffold A) was essential to get nanomolar anti-*T. brucei* activity. Accordingly, compounds with only one cation and no phenyl ring in *para* position (scaffold C) showed micromolar range IC₅₀. The 1-(2,3-dihydro-1*H*-inden-5-yl)guanidine derivative **32a** (IC₅₀ = 0.99 and 0.95 μ M against *T. b. rhodesiense* and *P. falciparum*, respectively) was the most active molecule of this series. On the contrary, the scaffold A compounds displayed nanomolar

activities with the exception of the compounds with an electron-attracting group such as SO₂ (**6a**, **6b** and **6e**) or CO (**5b**) linking both phenyl rings. Removal of one cationic moiety (scaffold B) or one phenyl-cationic moiety (scaffold C) led to a great loss of activity (e.g., compare 1a/15a/24a, 2a/16a/27a, 2b/16b/27b). Interestingly, the decrease in activity observed in homologous series with the removal of one cationic moiety (i.e., scaffold A \rightarrow B) was less pronounced for the bis(2-aminoimidazolinium) vs bisguanidinium compounds [e.g., compare 1a/15a (×218) vs 1b/15b (×17), 2a/16a (×98) vs 2b/16b (×5.5), 3a/17a (×96) vs 3b/17b (×10)]. Another remarkable effect of the 2-aminoimidazolinium cation was the higher selectivity for the parasite observed in all the cases as compared with the guanidinium analogues [e.g., 3a (SI = 8) vs 3b (SI = 88), 9a (SI = 319) vs 9b (SI = 7731), 14a (SI = 15) vs 14b (SI = 624)]. This observation was also true for the antiplasmodial activity of the dicationic compounds.

Regarding the bridge linking both phenyl rings, the same range of activity (IC₅₀ in the low micromolar range) was observed for electron donating groups: NH (1) ~ CH₂CH₂ (10) >> piperidine (11) ~ piperazine (12). Isosteric replacement of the CH₂ (2) by a sulfur (3) or oxygen atom (4) hardly changed the activity. The best activity was observed with an amide (9a, 9b) or ethane bridge (10a, 10b). Fused ring dicationic compounds 13 (fluorene) and 14 (dihydroanthracene) also gave excellent antitrypanosomal activity. The bis(2-aminoimidazoline)fluorene derivative 13b was the best anti-*T. brucei* agent in vitro (IC₅₀ = 4.9 nM, SI = 17000). This outstanding value is to be compared with the guanidine analogue 13a (IC₅₀ = 24 nM, SI = 196) previously described by Boykin and co-workers.¹³ Hence, replacement of the guanidine cations by 2-aminoimidazoline ones led to a 5-fold increase in activity and 86-fold increase in selectivity for this scaffold. Dicationic guanidine compounds (scaffold A) with NH, CH₂, O, S, CO or SO₂ bridge linking both phenyl rings were 2- to 10-fold more potent than their 2-aminoimidazoline counterparts (compare 1a/1b, 2a/2b, 3a/3b, 4a/4b, 5a/5b and 6a/6b). The opposite effect was observed for monocationic compounds (scaffold B). However, no significant difference in antitrypanosomal activities was observed between the bisguanidine and bis(2-aminoimidazoline) counterparts for the compounds with the urea (7a, 7b), amide (9a, 9b) or ethane bridge (10a, 10b).

Antiplasmodial activity. In most cases, the best activities for scaffolds A, B and C were observed for compounds bearing the 2-aminoimidazolinium cations except for the fluorene analogue 13b (IC₅₀ = 11.5 nM), the activity of which was 5-fold lower than that reported by Boykin and co-workers for the guanidine counterpart **13a** (2.3 nM).¹³ Among twenty dicationic compounds, which displayed IC_{50} values < 50 nM, diphenylamine derivative **1b** is the best antiplasmodial agent of the series (IC₅₀ = 8.8nM, SI = 24000). Most of the dicationic compounds displayed excellent antimalarial activities regardless of the linker X. However, compounds with an electron withdrawing linker [SO₂ (6), CO (5), NHCSNH (8)], exhibited somewhat lower activity. The remarkable in vitro antiplasmodial activities of the piperazine derivatives 12a and 12b $(IC_{50} = 15.2 \text{ and } 12.3 \text{ nM}, \text{ respectively})$ were comparable to that of their diamidine homologue reported by Mayence et al. $(IC_{50} = 4 \text{ nM})$.¹⁰ As observed for the antitrypanosomal activity, the removal of one cationic moiety from scaffold A compounds produced a dramatic loss of activity [Tables 1 and 2: compare 1b/15b (×62), 2b/16b (×108), 3a/17a (×171), 3b/17b (×150), 4b/18b (×48), 5b/19b (×40), 7a/20a (×42), 7b/20b (×121), 8a/21a (×14), 9a/22a (×241), 9b/22b (>535)].

The nanomolar activity observed for the uncharged Boc-substituted guanidine (1d) and imidazoline (1e, 6e) derivatives is worth noting. Interestingly, the bis(*n*-pentylphosphonium) dicationic analogue 5f (IC₅₀ = 53 nM, SI = 222) produced a 2-fold increase in activity together with a loss of selectivity with respect to its imidazoline counterpart 5b (IC₅₀ = 129 nM, SI > 1658). Altogether, the data seems to indicate that lipophilic groups, either cationic (phosphonium derivative 5f) or uncharged (Boc-protected compounds 1d and 1e), are allowed for good in vitro antiplasmodial activity of this class of symmetric diphenyl compounds.

In Vivo Activity (Tables 4 and 5)

The compounds displaying the best in vitro antitrypanosomal activities and selectivity were administered intraperitoneally to mice infected with *T. b. rhodesiense* STIB900. Five compounds (**7b**, **9a**, **9b**, **10b** and **14b**) cured all mice at 20 mg/kg whereas **11b** only cured 2/4 mice at this dose (Table 4). This data was somehow surprising because the in vitro activity and selectivity of **11b** and the other compounds tested were similar. Another interesting finding was the enhanced antitrypanosomal activity and reduced toxicity of the piperidine compound **11b** compared to the piperazine molecule **12a** (i.e., **12a** was toxic at 20 mg/kg in this model⁷). Apparently, the presence of tertiary amino groups in **12a** and **11b** is not favourable for good in vivo activity which may possibly relate to unfavourable pharmacokinetic properties of the compounds.

Hence, the in vivo activity of the new compounds in the difficult to cure STIB900 mouse model was comparable to that of the lead compound **1b** reported earlier.⁷ Additional experiments to determine the minimum curative dose, oral bioavailability and potential activity in the chronic CNS mouse model of sleeping sickness are ongoing.

In addition, ten compounds were tested in the *P. berghei* mouse model to check whether the excellent in vitro antiplasmodial activity of the dicationic compounds was retained in vivo. Four compounds (**1b**, **3b**, **4b** and **12a**) reduced significantly the parasitaemia upon ip treatment at 20–50 mg/kg but none of them was curative (Table 5). However, the bis(2-aminoimidazoline) derivative **4b** reduced parasitaemia drastically (97.5%) at 50 mg/kg and was able to increase mice survival almost 2-fold compared to control animals. This activity compared favourably with that of the control drug chloroquine at 5mg/kg. Besides, the ip administration of **3b** (30 mg/kg) produced an activity of 44.1% similar to its diamidine counterpart administered subcutaneously at 40 mg/kg.³¹ Altogether, the data confirm the antimalarial potential of the diphenyl amine, diphenylether and diphenyl sulfide scaffolds.

The rest of the compounds were either toxic at the tested dose of 50 mg/kg (7a, 10a, 11a and 14a) or inactive (12b). Taken together, the in vivo results suggest that, in this series, guanidine derivatives are more toxic than their cyclic congeners in agreement with the higher SI observed in vitro for the 2-aminoimidazoline analogues.

Insights into the mechanism of action.

(1) DNA binding affinity. Many aromatic diamidines and diguanidines are strong DNA minor groove binders.^{11, 32, 33} Some evidence suggests that this interaction is responsible to some extent for the antiprotozoal activity frequently displayed by this class of compounds. We previously reported the existence of a correlation between DNA binding affinity to AT-rich sites and in vitro antitrypanosomal activity of some of the dicationic compounds presented here (1a, 1c, 2a, 2c, 5f and 1b, 2b, 5a, 12a, 12b).⁷ In order to extend our knowledge of the structural requirements responsible for high-quality DNA minor groove binding, and possibly good antiprotozoal activity, the

thermal melting curves (ΔT_m) of the new set of compounds (**3a–b**, **4a–b**, **7–11a-b**, **13b** and **14a–b**) were determined using a nonalternating AT sequence DNA polymer. We used the same experimental conditions (i.e., low salt buffer) as reported before,⁷ thus allowing the comparison of the ΔT_m values of the entire series. The results of DNA binding of the previous set of compounds (**1**, **2**, **5** and **12**) and the new series (**3**, **4**, **7–11**, **13**, **14**) are presented in Table 6. Overall, strong DNA binding was observed for this new series of dicationic compounds with ΔT_m values ranging from 20.1 to 47.1 °C. The 2-aminoimidazoline derivatives consistently displayed higher ΔT_m values (2 to 7 °C) than the guanidine counterparts indicating that the ethylene bridge of the 2aminoimidazoline group confers some special features, possibly extra hydrophobic contacts with the walls of the groove that contribute positively to the binding of these compounds.³⁴ Curiously, the opposite effect is usually observed when comparing series of dicationic benzamidines and their imidazolines analogues, the amidine group conferring habitually better minor groove binders than the imidazoline counterparts.^{35–38}

Most interesting was the correlation observed between in vitro antiprotozoal activity and DNA binding affinity for the set of 2-aminoimidazoline compounds. Hence, plotting ΔT_m versus IC₅₀ against trypanosomes revealed the two to be correlated as shown in Figure 1a. In addition, a clear trend showing an increase in activity with an increase in ΔT_m was observed for the guanidine set of compounds (Figure 1b). The most exciting finding from this DNA binding affinity study was observed with the 2aminoimidazoline set of compounds, the SI of which correlated in a fairly good manner with the T_m increase (Figure 2). On the contrary, no correlation was observed for the guanidine set of analogues. (2) Inhibition of β -hematin formation. Earlier studies have shown that several diphenyldiamidine compounds displaying antiplasmodial activity bind effectively to FPIX in vitro inhibiting the crystallization of toxic FPIX into non-toxic hemozoin. The result of this interaction would be responsible for the antimalarial activity of that class of compounds.^{10, 15} We decided to test whether our bisguanidine and bis(2-aminoimidazoline) derivatives might work in the same way to evaluate this hypothesis. A simple in vitro assay,¹⁶ the detection by optical density measurement of solubilised β -haematin remaining after contact with drugs, was used to assess the capacity of our compounds to inhibit hemozoin biomineralisation (Table 7). Some of the compounds inhibited hemozoin formation at micromolar concentrations comparable to that of quinine (IC₅₀ = 324 μ M)¹⁶ though higher than chloroquine (IC₅₀ = 17.9 μ M). However, no correlation between in vitro antiplasmodial activity and hemozoin inhibition was observed.

Discussion

Encouraged by the excellent in vitro and in vivo trypanocidal activity of a series of dicationic diphenyl compounds previously discovered by our group,⁷ we report a continued investigation of 2-aminoimidazoline and guanidine analogues as potential antiplasmodial and antitrypanosomal agents. In vitro and in vivo data from three new series of derivatives revealed some important trends for the SAR of these compounds. In all the cases, the diphenyl dicationic compounds (scaffold A) were the most active antitrypanosomal and antiplasmodial compounds with IC_{50} values in the nanomolar range. These compounds were more efficient than their monocationic analogues which showed IC_{50} in the micromolar range (scaffold B) highlighting once more that the presence of two cationic groups is essential for consistent activity in this series. The

same trend was reported earlier with amidine containing diphenyl ureas active against *P. falciparum*,³⁹ guanidine diphenyl derivatives active against *T. equiperdum*,^{21, 40} or furamidine analogues.^{33, 41} In addition, some basic SAR emerged relating to the best linker between both phenyl rings (i.e., NH, NHCO and CH_2CH_2) and the best cation (i.e., 2-aminoimidazoline) to get selective compounds with good in vivo antitrypanosomal activity (Figure 3). Fused ring dicationic compounds (**13** and **14**) also exhibited excellent activity in agreement with the results reported earlier by Arafa et al.¹³ Interestingly, with regards to the linker between the two phenyl rings, our results agree to some extent with the findings of Turner²⁷ for a series of bis[1,6-dihydro-6,6-dimethyl-1,3,5-triazine-2,4-diamines]. Thus it appears that the 1,2-diphenylethane and fluorene moieties should be considered as good scaffolds for the design of symmetric dicationic antitrypanosomal drugs regardless of the cationic moiety present in the molecule.

We do not have a clear explanation concerning the extra selectivity and lower in vivo toxicity observed in all the cases with the 2-aminoimidazoline cations in comparison with the guanidine one. One may speculate whether the higher lipophilicity and/or a reduced H-bond donating capacity play a role in the reduced toxicity of the imidazoline derivatives. On the other hand, the observation that the 2-aminoimidazoline derivatives consistently displayed higher DNA binding affinity than the guanidine counterparts and the correlation observed between selectivity and T_m increase for this series suggest that the formation of a DNA complex may be an important issue to explain the MOA and selectivity profile of these dicationic derivatives. This new and quite exciting observation indicates that more investigations on 2-aminoimidazolines as DNA minor groove binders and antiprotozoal agents are warranted.

Of note was the excellent in vitro antiplasmodial activity of the urea dicationic derivatives **7a** and **7b** ($IC_{50} = 96$ and 28 nM, respectively). Similar activities had been reported for amidine-containing diphenyl ureas.³⁹ Interestingly, Jiang and co-workers have also reported micromolar in vitro anti–*P. falciparum* activity of a monocationic diphenyl urea compound. That compound, WR268961, the structure of which is related to **20** (i.e., scaffold B), was an inhibitor of the recombinant *P. falciparum* aspartic protease plasmepsin II.⁴² This is relevant because plasmepsins are validated targets for antimalarial therapy^{43–45} and the activity of **7**, **20** and **21** might be related to plasmepsin inhibition, even though this would need experimental confirmation.

Another exciting finding was the nanomolar activity exhibited by the Boc-protected compounds (**1d**, **1e**, and **6e**) against *P. falciparum* K1. The fair FPIX biomineralisation inhibition displayed by **1e** in the FBIT assay ($IC_{50} = 170.7 \mu M$) suggests that this compound could interfere in the heme detoxification process of the parasite. However, since these highly lipophilic precursors are uncharged molecules one might expect their pharmacodynamics to be different from the dicationic derivatives.

Despite the lack of correlation between FPIX biomineralisation inhibition and in vitro activity against *P. falciparum*, the binding to FPIX might be responsible to some extent for the observed antiplasmodial activity and/or for the accumulation of the compounds into the parasites as shown previously for some diamidine drugs.¹⁵ However, care should be taken in the interpretation of these results as we have no evidence at this time that these inhibitors are able to reach the food vacuole of the parasite to target the heme detoxification pathway. Indeed, additional MOA is likely to be involved since our dicationic compounds were less potent FPIX inhibitors than CQ whereas they showed nanomolar range activity about one order of magnitude superior to CQ against the *P. falciparum* CQ-resistant strain K1.

The diphenyl dicationic compounds retained only moderate activity in the *P. berghei* murine model, in contrast to CQ, which may possibly indicate unfavourable pharmacokinetic properties or a different MOA. On the other hand, the modest in vivo activity observed after ip administration in the *P. berghei* model does not necessarily mean that these diphenyl diguanidine compounds are poor antimalarials. In fact, some recent evidence suggests that the *P. berghei* mouse model might not be optimal to predict the activity of aromatic diamidines against human malaria.¹¹ For instance, DB289 which showed only modest activity in the *P. berghei* mouse model has shown remarkable activity in a human trial against *P. falciparum*.¹⁴ For that reason, we believe that these families of compounds deserve more thorough investigations of their in vivo antimalarial action.

Conclusion

In order to extend our understanding of the SAR of the bis(2-aminoimidazoline) lead compounds reported earlier,^{7, 8} we have screened a new series of symmetric dicationic guanidine and 2-aminoimidazoline aromatic analogues against *T. b. rhodesiense* and *P. falciparum*. We have shown that, in this series, the 2-aminoimidazoline derivatives were safer (higher SI) and more potent in vivo against *T. b. rhodesiense* than their guanidine counterparts. Moreover, a correlation between DNA binding affinity and selectivity towards the parasite was observed indicating that high affinity binding to the minor groove of DNA may be part of their mechanism of antitrypanosomal action. This view⁷ was also supported by the observation of a correlation between DNA binding affinity and selfinity and trypanocidal activity of two series of compounds.

Five new dicationic lead compounds (7b, 9a, 9b, 10b and 14b), upon ip administration of 20 (mg/kg)/day, cured 100% of treated mice in the *T. b. rhodesiense*

STIB900 model. On the contrary, despite their excellent in vitro antiplasmodial activity and capacity in reducing the parasitaemia of mice infected with *P. berghei*, the dicationic compounds **1b**, **2b**, **3b**, **4b**, and **12a** did not cure the animals in this model. However, the *P. berghei* mouse model may not be the best predictive model for this kind of dicationic compounds as we have pointed out before.

In this study we also described the excellent in vitro antiplasmodial activity of non cationic Boc-protected guanidines and imidazolines as well as phosphonium derivatives, the in vivo antimalarial efficacy of which is currently being evaluated. Hence, more thorough investigation on the antiplasmodial activity of this class of compounds is warranted.

In the light of these promising results, we believe that bis(2-aminoimidazoline) derivatives deserve more investigation as antiprotozoal agents and DNA minor groove binders. The synthesis and study of new derivatives and prodrugs of our lead compounds is ongoing and will be reported in due course.

Experimental section

Chemistry. All the commercial chemicals were obtained from Sigma–Aldrich, Fluka or Lancaster and were used without further purification. Deuterated solvents for NMR use were purchased from Apollo. Dry solvents were prepared using standard procedures, according to Vogel,⁴⁶ with distillation prior to use. Chromatographic columns were run using Silica gel 60 (230–400 mesh ASTM) or Aluminium Oxide (activated, Neutral Brockman I STD grade 150 mesh). Solvents for synthesis purposes were used at GPR grade. Analytical TLC was performed using Merck Kieselgel 60 F₂₅₄ silica gel plates or Polygram Alox N/UV₂₅₄ aluminium oxide plates. Visualisation was by UV light (254 nm). NMR spectra were recorded in a Bruker DPX–400 Avance spectrometer, operating at 400.13 MHz and 600.1 MHz for ¹H NMR and 100.6 MHz and 150.9 MHz for ¹³C NMR. Shifts are referenced to the internal solvent signals. NMR data were processed using Bruker Win–NMR 5.0 software. Electrospray mass spectra were recorded on a Mass Lynx NT V 3.4 on a Waters 600 controller connected to a 996 photodiode array detector with methanol, water or ethanol as carrier solvents. Melting points were determined using an Electrothermal IA9000 digital melting point apparatus and are uncorrected. Infrared spectra were recorded on a Mattson Genesis II FTIR spectrometer equipped with a Gateway 2000 4DX2–66 workstation and on a Perkin Elmer Spectrum One FT–IR Spectrometer equipped with Universal ATR sampling accessory. Sample analysis was carried out in nujol using NaCl plates. Elemental analysis was carried out at the Microanalysis Laboratory, School of Chemistry and Chemical Biology, University College Dublin. Analytical results were within ±0.4% of the theoretical (calcd) values except otherwise noted.

1) Synthesis of the starting material amines.

1,3-Bis(4-aminophenyl)urea (7).²⁷ A suspension of 5 g (16.5 mmol) of 1,3-bis(4nitrophenyl)urea in methanol in the presence of 5% Pd–C (480 mg) was hydrogenated at atmospheric pressure and room temperature for 22 h. Afterwards, the catalyst was filtered through a pad of celite. The filter cake was rinsed with MeOH:DMF (1:1) and the solvent removed *in vacuo* to afford 3.9 g (97%) of 1,3-bis(4-aminophenyl)urea **7** as a white solid; ¹H NMR (DMSO–d₆): δ 4.73 (broad s, 4H, NH₂), 6.51 (d, 4H, *J* = 8.0 Hz, Ar), 7.07 (d, 4H, *J* = 8.0 Hz, Ar), 8.08 (broad s, 2H, NH); ¹³C NMR (DMSO–d₆): δ 115.6, 121.8, 130.6, 145.0 (Ar), 154.8 (CO).

1,4-Bis(4-nitrophenyl)piperidine (11f). A solution of 2.5 g (12.1 mmol) of 4-(4-nitrophenyl)piperidine^{28, 29} and 1.712 g (12.1 mmol) of 1-fluoro-4-nitrobenzene in DMF (8 mL) was heated at 100 °C for 72 h. Afterwards, the solvent was removed *in vacuo*

and the residue obtained was recrystallised from CH₃CN to yield 2.95 g (74%) of 1,4bis(4-nitrophenyl)piperidine **11f** as a yellowish solid; mp 170–172 °C; MS (ESI⁺) *m/z* 350.1105 [M+Na]⁺; IR (nujol) v 1597, 1516 (NO₂) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.62– 1.80 (m, 2H, H₃Pip.), 1.83–1.97 (m, 2H, H₃Pip.), 2.99–3.19 (m, 3H, H_{2e}Pip + H₄Pip.), 4.16–4.31 (m, 2H, H_{2a}Pip.), 7.08 (d, 2H, *J* = 8.8 Hz, Ar), 7.56 (d, 2H, *J* = 7.8 Hz, Ar), 8.06 (d, 2H, *J* = 8.8 Hz, Ar), 8.17 (d, 2H, *J* = 7.8 Hz, Ar); ¹³C NMR (DMSO–d₆): δ 33.0 (C₃Pip), 42.7 (C₄Pip.), 48.4 (C₂Pip.), 113.9, 124.9, 127.2, 129.5, 137.6, 147.3, 154.8, 155.7 (Ar).

1,4-Bis(4-aminophenyl)piperidine (11). A suspension of 1.5 g (4.6 mmol) of 1,4bis(4-nitrophenyl)piperidine **11f** in methanol in the presence of 5% Pd–C (185 mg) was hydrogenated at 3 bar and room temperature for 22 h. Afterwards, the catalyst was filtered off and the solvent removed *in vacuo* to afford 1.198 g (98%) of **11** as a navy blue solid; mp 156–158 °C; MS (ESI⁺) *m/z* 268.1802 [M+H]⁺; IR (nujol) v 3365, 3297, 3201 (NH₂) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.63–1.80 (m, 4H, H₃Pip.), 2.32–2.43 (m, 1H, H₄Pip.), 2.53–2.61 (m, 2H, H_{2e}Pip.), 3.38–3.49 (m, 2H, H_{2a}Pip.), 4.58 (broad s, 2H, NH₂), 4.85 (broad s, 2H, NH₂), 6.46–6.54 (m, 4H, Ar), 6.73 (d, 2H, *J* = 8.8 Hz, Ar), 6.92 (d, 2H, *J* = 8.3 Hz, Ar); ¹³C NMR (DMSO–d₆): δ 35.1 (C₃Pip.), 42.1 (C₄Pip.), 53.3 (C₂Pip.), 115.4, 116.2, 120.0, 128.4, 134.9, 143.4, 144.5, 148.0 (Ar).

1-(4-aminophenyl)-3-phenylurea (20). 1.10 mL (10.0 mmol) of phenyl isocyanate was added under an inert atmosphere and at 0 °C over a solution of 1.082 g (10.0 mmol) of 1,4-phenylenediamine in dry CH_2Cl_2 (10 mL). The mixture was allowed to reach room temperature and was stirred for 10 minutes. The white solid precipitated was filtered and washed with cold CH_2Cl_2 to afford 2.15 g (95%) of the pure 1-(4-

aminophenyl)-3-phenylurea; mp decomposes over 212 °C (Lit.⁴⁷: 260 °C); IR (nujol) v 3353, 3292, 3181 (NH, NH₂), 1622 (CO; Lit.⁴⁸: 1630) cm⁻¹; ¹H NMR (DMSO–d₆): δ 4.80 (broad s, 2H, NH₂), 6.56 (d, 2H, J = 8.5 Hz, Ar), 6.88–6.99 (m, 1H, Ar), 7.12 (d, 2H, J = 8.5 Hz, Ar), 7.21–7.30 (m, 2H, Ar), 7.46 (d, 2H, J = 8.0 Hz, Ar), 8.17 (broad s, 1H, NH), 8.51 (broad s, 1H, NH); ¹³C NMR (DMSO–d₆): δ 115.5, 119.3, 122.2, 122.7, 129.9, 130.1, 141.5, 145.4 (Ar), 154.3 (CO).

4-(*tert*-butoxycarbonylamino)benzamide (22c). Aniline (930 mg, 10 mmol) and TBTU (3.211 g, 10 mmol) were added at 0 °C and under argon over a solution containing 4-[(*tert*-butoxycarbonyl)amino]benzoic acid (2.373 g, 10.0 mmol) and Et₃N (5.6 mL, 40 mmol) in 15 mL of dry CH₂Cl₂. The reaction mixture was stirred at room temperature for 7 hours. After that time a white precipitate was formed. This precipitate turned out to be the desired compound and was filtered and washed with cold hexane to yield 2.3 g (74%) of 4-(*tert*-butoxycarbonylamino)benzamide as a white solid; mp 205–207 °C; IR (nujol) v 3352, 3330 (NH), 1704, 1646 (CO) cm⁻¹. ¹H NMR (DMSO–d₆): δ 1.51 (s, 9H, (CH₃)₃), 7.06–7.15 (m, 1H, Ar), 7.32–7.42 (m, 2H, Ar), 7.54–7.67 (m, 2H, Ar), 7.74–7.85 (m, 2H, Ar), 7.89–7.99 (m, 2H, Ar), 9.72 (broad s, 1H, NH), 10.09 (broad s, 1H, NH); ¹³C NMR (DMSO–d₆): δ 29.4 ((CH₃)₃), 80.9 (C(CH₃)₃), 118.5, 121.7, 124.8, 129.4, 129.9, 130.0, 140.7, 144.1 (Ar), 154.0 ((CH₃)₃COCO), 166.3 (PhNHCOPh).

4-aminobenzanilide (22). A solution of 3.113 g (10.0 mmol) of **22c** in 35 mL of CH₂Cl₂:TFA (1:1) was stirred at room temperature for 6 h. After that time, the solvent was eliminated under vacuum to generate the trifluoroacetate salt. This salt was redissolved in 20 mL of CH₂Cl₂ and was washed with a 2M NaOH solution (2 × 15

mL). The organic layer was dried over anhydrous Na₂SO₄, filtered and the solvent was evaporated to afford 1.961 g (93%) of 4-aminobenzanilide as a white solid; mp 136–138 °C (Lit.⁴⁹: 138–140 °C); IR (nujol) v 3393, 3350, 3184 (NH, NH₂), 1644 (CO) cm⁻¹; ¹H NMR (DMSO–d₆)⁵⁰: δ 5.79 (broad s, 2H, NH₂), 6.64 (d, 2H, J = 8.8 Hz, Ar), 7.02–7.11 (m, 1H, Ar), 7.31–7.40 (m, 2H, Ar), 7.72–7.86 (m, 4H, Ar), 9.80 (broad s, 1H, NH); ¹³C NMR (DMSO–d₆): δ 113.9, 121.5, 122.4, 124.2, 129.8, 130.7, 141.1, 153.5 (Ar), 166.7 (CO).

2) Synthesis of Boc-protected precursors and new tested compounds.

A. General method for the synthesis of the Boc-protected guanidine and Bocprotected 2-aminoimidazoline precursors: 6.6 mmol of HgCl₂ were added over a solution of 3.0 mmol of the corresponding diamine, 6.0 mmol of N,N'-di(tertbutoxycarbonyl)thiourea (for 7d, 9d, and 11d) *N*,*N*'-di(*tert*or butoxycarbonyl)imidazolidine-2-thione (for 7e, 9e, and 11e) and 2.1 mL (15.0 mmol) of Et₃N in DMF (10 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and for the appropriate duration at room temperature. Then, the reaction mixture was diluted with EtOAc and filtered through a pad of Celite. The filter cake was rinsed with EtOAc. The organic phase was extracted with water (2 \times 30 mL), washed with brine (1 \times 30 mL), dried over anhydrous Na₂SO₄ and concentrated under vacuum to give a residue that was purified by column chromatography as specified.

B. General method for the removal of the Boc-protecting groups and regeneration of the hydrochloride salts. A solution of the corresponding Boc-protected derivative (0.5 mmol) in 20 mL of CH_2Cl_2 :TFA (1:1) was stirred at room temperature for the appropriate duration. After that time, the solvent was eliminated

under vacuum to generate the trifluoroacetate salt. This salt was dissolved in 20 mL of water and treated for 24 h with IRA400 Amberlyte resin in its Cl⁻ form. Then, the resin was removed by filtration and the aqueous solution washed with CH_2Cl_2 (2 × 10 mL). Evaporation of the water afforded the pure dihydrochloride salt as a hygroscopic solid. Absence of the trifluoroacetate salt was checked by ¹⁹F NMR.

C. Alternative method for the synthesis of the Boc-protected guanidines 20d, 21d and 23d. A solution of 4-[2,3-di(*tert*-butoxycarbonyl)guanidino]aniline 8 in dry CH_2Cl_2 was treated under an inert atmosphere and at 0 °C with the corresponding electrophile (phenyl isocyanate for 20d, phenyl isothiocyanate for 21d and benzoyl chloride for 23d) and with Et_3N (only in the case of 23d). After allowing the reaction mixture to reach room temperature it was stirred for the appropriate duration. Further work up followed by column cromatography as specified afforded the corresponding Boc-protected guanidine.

1,3-Bis(4-[2,3-di(*tert***-butoxycarbonyl)guanidino]phenyl)urea (7d)**. Following the general synthetic **method A**, the crude residue was purified by silica gel column chromatography, eluting with hexane:EtOAc (3:1) to yield 1.24 g (57%) of **7d** as a white solid; mp > 300 °C; MS (ESI⁺) *m/z* 727.3777 [M+H]⁺; IR (nujol) v 3368, 3307, 3264 (NH), 1720, 1644, 1624, 1605 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.46 (s, 18H, (CH₃)₃), 1.58 (s, 18H, (CH₃)₃), 7.25 (d, 4H, *J* = 8.5 Hz, Ar), 7.29 (d, 4H, *J* = 8.5 Hz, Ar), 7.40 (broad s, 2H, NHCONH), 10.14 (broad s, 2H, NH_{Gu}), 11.64 (broad s, 2H, NH_{Gu}); ¹³C NMR (CDCl₃): δ 28.0, 28.1 ((CH₃)₃), 80.0, 83.8 (<u>C</u>(CH₃)₃), 118.8, 124.8, 129.9, 137.6 (Ar), 152.1, 153.1 ((CH₃)₃CO<u>C</u>O), 155.3, 163.2 (NHCONH, CN).

1,3-Bis(4-[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]phenyl)urea (7e). Following the general synthetic **method A**. The crude residue was purified by neutral alumina column flash chromatography, eluting with CH₂Cl₂:EtOAc (1:5). The residue obtained after the column was precipitated with cold hexane to yield 1.25 g (63%) of 7e as a white solid; mp 180–182 °C; IR (nujol) v 3357 (NH), 1757, 1704, 1648 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.33 (s, 36H, (CH₃)₃), 3.83 (s, 8H, CH₂), 6.90 (d, 4H, *J* = 7.0 Hz, Ar), 7.14–7.26 (m, 6H, 4Ar + 2NH); ¹³C NMR (CDCl₃): δ 27.8 ((CH₃)₃), 43.1 (CH₂), 82.9 (<u>C</u>(CH₃)₃), 120.6, 121.8, 133.9, 139.3 (Ar), 143.4 ((CH₃)₃CO<u>C</u>O), 150.2, 153.5 (NHCONH, CN).

Dihydrochloride salt of 1,3-bis(4-guanidinophenyl)urea (7a). Following the general **method B**, 210 mg (95%) of the pure dihydrochloride salt of **7a** were obtained as a white solid; mp decomposes over 248 °C; MS (ESI⁺) m/z 327.1928 [M+H]⁺; ¹H NMR (D₂O): δ 7.27 (d, 4H, J = 8.5 Hz, Ar), 7.43 (d, 4H, J = 8.5 Hz, Ar); ¹³C NMR (D₂O): δ 121.6, 126.4, 129.1, 137.0 (Ar), 155.0, 156.0 (CO, CN); Anal. (C₁₅H₂₀Cl₂N₈O⁻2.3H₂O) C, H, N.

1,3-Bis(4-[2,3-di(*tert***-butoxycarbonyl)guanidino]phenyl)thiourea (8d)**. A solution of 701 mg (2.0 mmol) of 4-[2,3-di(*tert*-butoxycarbonyl)guanidino]aniline **8** and carbon disulfide 3.0 mL (50.0 mmol) in 20 mL of CH₂Cl₂ was stirred at reflux for 54 h. Afterwards, the solvent was evaporated to give a residue that was purified by silica gel column chromatography, eluting with hexane:EtOAc (3:2) to yield 240 mg (32%) of 8d as a white solid; mp > 300 °C; MS (ESI⁺) *m/z* 743.3412 [M+H]⁺; IR (nujol) v 3396, 3291, 3169 (NH), 1720, 1646, 1630, 1152 (CO, CN, CS) cm⁻¹; ¹H NMR (CDCl₃): δ 1.50 (s, 18H, (CH₃)₃), 1.55 (s, 18H, (CH₃)₃), 7.34 (d, 4H, *J* = 8.0 Hz, Ar), 7.61 (d, 4H, J = 8.0 Hz, Ar), 7.61 (d, 4H, Az) = 8.0 Hz, Az (d, 4H, Az) = 8.0 Hz, Az (d, 4Hz, Az), 7.61 (d, 4Hz, Az)

J = 8.0 Hz, Ar), 7.98 (broad s, 2H, NHCSNH), 10.36 (broad s, 2H, NH_{Gu}), 11.63 (broad s, 2H, NH_{Gu}); ¹³C NMR (CDCl₃): δ 27.8, 27.9 ((CH₃)₃), 79.6, 83.6 (<u>C</u>(CH₃)₃), 123.4, 124.9, 134.0, 134.8 (Ar), 152.9, 153.8 (CO), 163.1 (CN), 179.4 (CS).

4,4'-Bis[2,3-di(*tert*-butoxycarbonyl)guanidino]benzanilide (9d). Following the general synthetic **method A**. The crude residue was purified by silica gel column chromatography, eluting with hexane:EtOAc (2:1) to yield 1.3 g (61%) of **9d** as a white solid; mp > 300 °C; MS (ESI⁺) *m/z* 712.3635 [M+H]⁺; IR (nujol) v 3368, 3291, 3261 (NH), 1738, 1720, 1645, 1627, 1608 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.48 (s, 9H, (CH₃)₃), 1.51 (s, 9H, (CH₃)₃), 1.56 (s, 18H, (CH₃)₃), 7.54 (d, 2H, *J* = 8.6 Hz, Ar), 7.64 (d, 2H, *J* = 8.0 Hz, Ar), 7.68 (d, 2H, *J* = 8.0 Hz, Ar), 7.82 (d, 2H, *J* = 8.6 Hz, Ar), 8.19 (broad s, 1H, PhNHCOPh), 10.30 (broad s, 1H, NH_{Gu}), 10.51 (broad s, 1H, NH_{Gu}), 11.63 (broad s, 2H, NH_{Gu}); ¹³C NMR (CDCl₃): δ 27.9, 28.0 ((CH₃)₃), 79.6, 80.0, 83.6, 84.0 (<u>C</u>(CH₃)₃), 120.6, 122.1, 123.4, 128.1, 131.2, 132.1, 135.9, 139.3 (Ar), 153.2, 153.7, 154.0 ((CH₃)₃)CO<u>C</u>O), 163.1, 163.4 (CN), 165.2 (PhNH<u>C</u>OPh).

4,4'-Bis[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]benzanilide (9e). Following the general synthetic **method A**, the crude residue was purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc (1:4). The residue obtained after the column was recrystallised from Et₂O to yield 1.040 g (45%) of **9e** as a white solid; mp 198–200 °C; IR (nujol) v 3346 (NH), 1733, 1709, 1689, 1663, 1598 (CO, CN) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.30 (s, 36H, (CH₃)₃), 3.77 (s, 4H, CH₂), 3.80 (s, 4H, CH₂), 6.83 (d, 2H, *J* = 8.5 Hz, Ar), 6.92 (d, 2H, *J* = 8.5 Hz, Ar), 7.66 (d, 2H, *J* = 8.5 Hz, Ar), 9.92 (broad s, 1H, NH); ¹³C NMR (DMSO– d₆): δ 28.4, 28.5 ((CH₃)₃), 43.9, 44.0 (CH₂), 82.4, 82.6 (<u>C</u>(CH₃)₃), 121.3, 121.6, 121.7, 128.6, 129.3, 134.8, 139.8, 141.0 (Ar), 145.1, 150.4, 150.6, 152.9 ((CH₃)₃CO<u>C</u>O), CN), 165.4 (PhNH<u>C</u>OPh).

1.4-Bis $[4-(N^2, N^3-bis(tert-butyloxycarbonyl)guanidino)phenyl]piperidine$ (11d). General method A with 598 mg (2.2 mmol) of HgCl₂, 268 mg (1.0 mmol) of 11, 553 mg (2.0 mmol) of N,N'-di(tert-butoxycarbonyl)thiourea and 0.9 mL (6.4 mmol) of Et₃N in CH₂Cl₂:DMF (1:2) (8 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 36 h more at room temperature. After general workup, the residue was purified by silica gel column chromatography, eluting with hexane:EtOAc (3:1) to yield 483 mg (64%) of 11d as a white solid; mp decomposes over 220 °C; MS (ESI⁺) m/z 752.4326 [M+H]⁺; IR (nujol) v 3291, 3266 (NH), 1728, 1638, 1608 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.52 (s, 18H, (CH₃)₃), 1.55 (s, 18H, (CH₃)₃), 1.82–2.00 (m, 4H, H₃Pip.), 2.56-2.69 (m, 1H, H₄Pip.), 2.71-2.89 (m, 2H, H_{2e}Pip.), 3.71-3.82 (m, 2H, H_{2a}Pip.), 6.95 (d, 2H, J = 8.0 Hz, Ar), 7.22 (d, 2H, J = 7.0 Hz, Ar), 7.48 (d, 2H, J = 8.0 Hz, Ar), 7.54 (d, 2H, J = 7.0 Hz, Ar), 10.19 (broad s, 1H, NH), 10.29 (broad s, 1H, NH), 11.68 (broad s, 2H, NH); ¹³C NMR (CDCl₃): δ 28.0, 28.1, 28.2 ((CH₃)₃), 33.1 (C₃Pip.), 41.8 (C₄Pip.), 50.8 (C₂Pip.), 79.3, 79.4, 83.3, 83.5 (<u>C</u>(CH₃)₃), 117.0, 122.4, 123.3, 127.2, 128.7, 134.7, 142.5, 149.0 (Ar), 153.2, 153.3, 153.4, 153.5 (CO), 163.5, 163.6 (CN).

Di-tert-butyl-2-(4-[4-(4-[1,3-bis(tert-butyloxycarbonyl)-tetrahydro-1H-2-

imidazolyliden]aminophenyl)piperidino]phenylimino)-1,3-

imidazolidinedicarboxylate (11e). Method A with 598 mg (2.2 mmol) of HgCl₂, 268 mg (1.0 mmol) of **11**, 605 mg (2.0 mmol) of N,N'-di(*tert*-butoxycarbonyl)imidazolidine-2-thione and 0.9 mL (6.4 mmol) of Et₃N in CH₂Cl₂:DMF

(1:2) (8 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 41 h more at room temperature. The reaction was worked up and purified by silica gel column chromatography, eluting with hexane:EtOAc (1:1). The residue obtained after the column was recrystallised from hexane:Et₂O (1:1) to yield 523 mg (65%) of **11e** as a white solid; mp 191–193 °C; MS (ESI⁺) *m/z* 804.4681 [M+H]⁺; IR (nujol) v 1753, 1704, 1662, 1606 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.32 (s, 18H, (CH₃)₃), 1.34 (s, 18H, (CH₃)₃), 1.83–1.98 (m, 4H, H₃Pip.), 2.49–2.61 (m, 1H, H₄Pip.), 2.66–2.79 (m, 2H, H_{2e}Pip.), 3.60–3.71 (m, 2H, H_{2a}Pip.), 3.83 (s, 8H, CH₂), 6.85–7.0 (m, 6H, Ar), 7.11 (d, 2H, *J* = 8.0 Hz, Ar); ¹³C NMR (CDCl₃): δ 27.8, 27.9 ((CH₃)₃), 13.4 (C₃Pip.), 41.8 (C₄Pip.), 43.0 (CH₂), 51.8 (C₂Pip.), 82.5, 82.7 (<u>C</u>(CH₃)₃), 117.8, 121.4, 122.2, 126.9, 138.4, 139.0, 140.4, 141.1 (Ar), 146.4, 148.0 (CO); 150.3, 150.4 (CN).

Trihydrochloride salt of 1,4-bis(4-guanidinophenyl)piperidine (11a). Following method B, 224 mg (90%) of the pure hydrochloride salt of 11a were obtained as a brown solid; mp = decomposes over 220 °C; ¹H NMR (D₂O): δ 2.19–2.33 (m, 4H, H₃Pip.), 3.10–3.24 (m, 1H, H₄Pip.), 3.80–3.93 (m, 4H, H₂Pip.), 7.32 (d, 2H, *J* = 8.0 Hz, Ar), 7.48 (d, 2H, *J* = 8.0 Hz, Ar), 7.54 (d, 2H, *J* = 8.5 Hz, Ar), 7.78 (d, 2H, *J* = 8.5 Hz, Ar); ¹³C NMR (D₂O): δ 29.9 (C₃Pip.), 37.4 (C₄Pip.), 56.3 (C₂Pip.), 122.3, 125.8, 126.6, 127.8, 132.3, 135.9, 139.4, 142.9 (Ar), 155.6, 155.9 (CN). Anal. (C₁₉H₂₈Cl₃N₇·2 H₂O) C, H, N.

Trihydrochloridesaltof1,4-bis[4-(4,5-dihydro-1*H*-2-imidazolylamino)phenyl]piperidine (11b). Following method B, 279 mg (94%) of thepure hydrochloride salt of 11b were obtained as a brown solid; mp 101–103 °C; MS (ESI^+) m/z 404.2578 $[M+H]^+$; ¹H NMR (D₂O): δ 2.14–2.29 (m, 4H, H₃Pip.), 3.07–3.19(m, 1H, H₄Pip.), 3.72 (s, 4H, CH₂), 3.76 (s, 4H, CH₂), 3.74–3.86 (m, 4H, H₂Pip.), 7.26

(d, 2H, J = 8.6 Hz, Ar), 7.43 (d, 2H, J = 8.0 Hz, Ar), 7.49 (d, 2H, J = 8.6 Hz, Ar), 7.75 (d, 2H, J = 8.0 Hz, Ar); ¹³C NMR (D₂O): δ 29.8 (C₃Pip.), 37.3 (C₄Pip.), 42.2, 42.3 (CH₂), 56.3 (C₂Pip.), 122.2, 124.0, 125.0, 127.7, 133.2, 136.5, 138.9, 142.3 (Ar), 157.8, 158.2 (CN); Anal. (C₂₃H₃₂Cl₃N₇·2.3H₂O) C, H, N.

4-[2,3-di(*tert*-butoxycarbonyl)guanidino]benzophenone (19d). Method A with 896 mg (3.3 mmol) of HgCl₂, 592 mg (3.0 mmol) of 4-aminobenzophenone, 830 mg (3.0 mmol) of *N*,*N*'-di(*tert*-butoxycarbonyl)thiourea and 1.3 mL (9.3 mmol) of Et₃N in DMF (5 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 48 h more at room temperature. The reaction was worked up and purified by silica gel column chromatography, eluting with hexane:EtOAc (2:1) to yield 976 mg (74%) of **19d** as a white solid; mp 151–153 °C; IR (nujol) v 3197, 3154 (NH), 1718, 1656, 1643, 1595 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.53 (s, 9H, (CH₃)₃), 1.56 (s, 9H, (CH₃)₃), 7.44–7.51 (m, 2H, Ar), 7.54–7.60 (m, 1H, Ar), 7.75–7.86 (m, 6H, Ar), 10.63 (broad s, 1H, NH), 11.66 (broad s, 1H, NH); ¹³C NMR (CDCl₃): δ 28.0, 28.1 ((CH₃)₃), 80.0, 84.1 (<u>C</u>(CH₃)₃), 120.9, 128.1, 129.8, 131.3, 132.1, 133.2, 137.8, 140.8 (Ar), 153.1, 153.2 ((CH₃)₃CO<u>C</u>O), 163.2 (CN), 195.6 (PhCOPh).

4-[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]benzophenone (19e). **Method A** with 896 mg (3.3 mmol) of HgCl₂, 592 mg (3.0 mmol) of 4aminobenzophenone, 907 mg (3.0 mmol) of N,N'-di(*tert*-butoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in DMF (5 mL). The resulting mixture was stirred at 0 °C for 1 h and 48 h more at room temperature. The reaction was worked up and purified by neutral alumina column flash chromatography, eluting with hexane: EtOAc (2:3). The residue obtained after the column was precipitated and washed with cold hexane: Et₂O (1:1) to yield 600 mg (43%) of **19e** as a white solid; mp 49–51 °C; IR (nujol) v 1750, 1719, 1644 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.28 (s, 18H, (CH₃)₃), 3.78 (s, 4H, CH₂), 6.96 (d, 2H, J = 8.5 Hz, Ar), 7.33–7.39 (m, 2H, Ar), 7.41–7.48 (m, 1H, Ar), 7.61–7.70 (m, 4H, Ar); ¹³C NMR (CDCl₃): δ 27.5 ((CH₃)₃), 42.9 (CH₂), 82.6 (<u>C</u>(CH₃)₃), 120.6, 127.7, 129.2, 130.7, 131.1, 131.4, 138.1, 140.1 (Ar), 149.5 ((CH₃)₃CO<u>C</u>O), 152.9 (CN), 195.4 (PhCOPh).

Hydrochloride salt of 4-guanidinobenzophenone (19a). Following **method B**, 145 mg (97%) of the pure hydrochloride salt of **19a** was obtained as a white solid; mp 187–189 °C; MS (ESI⁺) *m/z* 240.1208 [M+H]⁺; ¹H NMR (D₂O): δ 7.15 (d, 2H, *J* = 8.0 Hz, Ar), 7.23–7.31 (m, 2H, Ar), 7.40 (d, 2H, *J* = 8.0 Hz, Ar), 7.44–7.52 (m, 3H, Ar); ¹³C NMR (D₂O): δ 122.7, 127.9, 129.5, 131.4, 132.9, 133.7, 135.6, 138.7 (Ar), 154.9 (CN), 197.6 (CO).

Hydrochloride salt of 4-(2-imidazolidinylimino)benzophenone (19b). Following method B, 156 mg (92%) of the pure hydrochloride salt of 19b were obtained as a yellow solid; mp 64–66 °C; MS (ESI⁺) m/z 266.1324 [M+H]⁺; ¹H NMR (D₂O): δ 3.64 (s, 4H, CH₂), 7.01 (d, 2H, J = 8.8 Hz, Ar), 7.18–7.25 (m, 2H, Ar), 7.31 (d, 2H, J = 7.2 Hz, Ar), 7.34–7.43 (m, 3H, Ar); ¹³C NMR (D₂O): δ 42.2 (CH₂), 120.7, 127.9, 129.4, 131.4, 132.8, 133.0, 135.5, 139.2 (Ar), 156.5 (CN), 197.1 (CO); Anal. Calc. (C₁₆H₁₆ClN₃O⁻2.0H₂O) C, H, N.

1-(4-[2,3-di(*tert*-butoxycarbonyl)guanidino]phenyl)-3-phenylurea (20d). Method A with 896 mg (3.3 mmol) of HgCl₂, 682 mg (3.0 mmol) of 1-(4-aminophenyl)-3-phenylurea 20, 830 mg (3.0 mmol) of N,N'-di(*tert*-butoxycarbonyl)thiourea and 1.3 mL (9.3 mmol) of Et₃N in DMF (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C

for 1 h and 26 h more at room temperature. Then, the reaction mixture was diluted with EtOAc and filtered through a pad of Celite. The filter cake was rinsed with EtOAc. The organic phase was extracted with water (2×30 mL), washed with brine (1×30 mL), dried over anhydrous Na₂SO₄ and concentrated under vacuum to give a residue that was purified by silica gel column chromatography, eluting with hexane:EtOAc (1:1) to yield 940 mg (67%) of **20d** as a white solid.

Method C: 0.33 mL (3.0 mmol) of phenyl isocyanate were added under an inert atmosphere and at 0 °C over a solution of 1.052 g (3.0 mmol) of 4-[2,3-di(*tert*-butoxycarbonyl)guanidino]aniline **8** in dry CH₂Cl₂ (10 mL). The mixture was allowed to reach room temperature and was stirred for 10 h. Then, the solvent was removed *in vacuo* and the residue obtained was purified by silica gel column chromatography, eluting with hexane:EtOAc (1:1). The pure compound **20d** was obtained as a white solid (1.034 g, 73%) by recrystallization from hexane:CH₂Cl₂; mp > 300 °C; MS (ESI⁺) *m/z* 470.2425 [M+H]⁺; IR (nujol) v 3300 (NH), 1726, 1633, 1600, 1568 (CO, CN) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.42 (s, 9H, (CH₃)₃), 1.53 (s, 9H, (CH₃)₃), 6.94–7.02 (m, 1H, Ar), 7.24–7.33 (m, 2H, Ar), 7.38–7.53 (m, 6H, Ar), 8.69 (broad s, 1H, NHCONH), 8.71 (broad s, 1H, NHCONH), 9.96 (broad s, 1H, NH_{Gu}), 11.54 (broad s, 1H, NH_{Gu}); ¹³C NMR (DMSO–d₆): δ 28.9, 29.2 ((CH₃)₃), 80.0, 84.6 (<u>C</u>(CH₃)₃), 119.5, 119.6, 123.1, 125.1, 130.1, 131.8, 138.2, 141.0 (Ar), 153.6, 153.8, 154.5, 164.2 ((CH₃)₃)CO<u>C</u>O, CN, NHCONH).

1-(4-[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]phenyl)-3-phenylurea (20e). Method A with 896 mg (3.3 mmol) of HgCl₂, 682 mg (3.0 mmol) of 20, 907 mg (3.0 mmol) of N,N'-di(*tert*-butoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in DMF (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 38 h more at room temperature. Then, the reaction mixture was diluted with EtOAc and filtered through a pad of Celite. The filter cake was rinsed with EtOAc. The organic phase was extracted with water (2 ×30 mL), washed with brine (1 × 30 mL), dried over anhydrous Na₂SO₄ and concentrated under vacuum to give a residue that was purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc:CH₂Cl₂ (6:4:1) to yield 924 mg (62%) of **20e** as a white solid; mp 162–164 °C; IR (nujol) v 3365 (NH), 1739, 1728, 1708, 1694 (CO, CN) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.29 (s, 18H, (CH₃)₃), 3.75 (s, 4H, CH₂), 6.79 (d, 2H, *J* = 7.0 Hz, Ar), 6.92–7.01 (m, 1H, Ar), 7.23–7.36 (m, 4H, Ar), 7.45 (d, 2H, *J* = 7.5 Hz, Ar), 8.51 (broad s, 1H, NH), 8.57 (broad s, 1H, NH); ¹³C NMR (DMSO–d₆): δ 28.8 ((CH₃)₃), 44.2 (CH₂), 82.7 (<u>C</u>(CH₃)₃), 119.4, 120.0, 122.5, 122.9, 130.1, 135.5, 140.0, 141.2 (Ar), 144.3, 151.0, 153.8 ((CH₃)₃CO<u>C</u>O, CN, NHCONH).

Trifluoroacetate salt of 1-(4-guanidinophenyl)-3-phenylurea (20a). A solution of 235 mg (0.5 mmol) of **20d** in 20 mL of CH₂Cl₂:TFA (1:1) was stirred at room temperature for 3 h. After that time, the solvent was eliminated under vacuum and cold water was added to generate a precipitate that was filtered, washed with 100 more mL of cold water and dried to yield 176 mg (91%) of the pure trifluoroacetate salt as a purple solid; mp 116–118 °C; MS (ESI⁺) *m/z* 270.1328 [M+H]⁺; ¹H NMR (CD₃OD): δ 6.96–7.03 (m, 1H, Ar), 7.18 (d, 2H, *J* = 8.5 Hz, Ar), 7.23–7.31 (m, 2H, Ar), 7.36–7.45 (m, 2H, Ar), 7.43 (d, 2H, *J* = 8.0 Hz, Ar); ¹³C NMR (CD₃OD): δ 120.5, 121.4, 123.8, 124.0, 127.7, 129.8, 140.3, 140.4 (Ar), 155.3, 158.3 (CN, CO); ¹⁹F NMR (CD₃OD): δ - 79.35; Anal. (C₁₆H₁₆F₃N₅O₃·0.2H₂O) C, H, N.

Trifluoroacetate salt of 1-[4-(2-imidazolidinylimino)phenyl]-3-phenylurea (20b). A solution of 248 mg (0.5 mmol) of **20e** in 20 mL of CH₂Cl₂:TFA (1:1) was stirred at room temperature for 3 h. After that time, the solvent was eliminated under vacuum and cold water was added to generate a precipitate that was filtered, washed with 100 more mL of cold water and dried to yield 194 mg (89%) of the pure trifluoroacetate salt as a grey solid; mp 102–104 °C; MS (ESI⁺) *m*/z 296.1522 [M+H]⁺; ¹H NMR (CD₃OD): δ 3.73 (s, 4H, CH₂), 6.96–7.04 (m, 1H, Ar), 7.18 (d, 2H, *J* = 9.0 Hz, Ar), 7.22–7.30 (m, 2H, Ar), 7.44 (d, 2H, *J* = 7.6 Hz, Ar), 7.53 (d, 2H, *J* = 9.0 Hz, Ar); ¹³C NMR (CD₃OD): δ 44.1 (CH₂), 120.5, 121.2, 124.0, 126.3, 129.8, 130.9, 140.1, 140.3 (Ar), 155.3, 160.4 (CN, CO); ¹⁹F NMR (CD₃OD): δ -78.90; Anal. (C₁₈H₁₈F₃N₅O₃·1.4H₂O) C, H, N.

1-(4-[2,3-di(*tert*-butoxycarbonyl)guanidino]phenyl)-3-phenylthiourea (21d).

Method C with 0.37 mL (3.0 mmol) of phenyl isothiocyanate and 1.052 g (3.0 mmol) of 4-[2,3-di(*tert*-butoxycarbonyl)guanidine]aniline **8** in dry CH₂Cl₂ (10 mL). The mixture was allowed to reach room temperature and was stirred for 18 h. Then, the solvent was removed *in vacuo* and the residue obtained was purified by silica gel column chromatography, eluting with hexane:EtOAc (1:1). The pure compound, **21d**, was obtained as a white solid (988 mg, 68%) by recrystallization from hexane: CH₂Cl₂; mp 120–122 °C; MS (ESI⁺) *m/z* 486.2248 [M+H]⁺; IR (nujol) v 3291, 3247, 3165, 3099 (NH), 1717, 1644, 1599, 1150 (CO, CN, CS) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.43 (s, 9H, (CH₃)₃), 1.54 (s, 9H, (CH₃)₃), 7.09–7.17 (m, 1H, Ar), 7.29–7.40 (m, 2H, Ar), 7.43–7.62 (m, 6H, Ar), 9.82 (broad s, 1H, NHCSNH), 9.83 (broad s, 1H, NHCSNH), 10.02 (broad s, 1H, NH_{Gu}), 11.50 (broad s, 1H, NH_{Gu}); ¹³C NMR (DMSO–d₆): δ 29.0, 29.2 ((CH₃)₃), 80.1, 84.7 (<u>C</u>(CH₃)₃), 124.2, 124.9, 125.2, 125.7, 129.7, 134.2, 137.6, 140.8 (Ar), 153.5, 154.2 (CO), 164.1 (CN), 180.8 (CS).

1-(4-[1,3-di(tert-butoxycarbonyl)-2-imidazolidinylimino|phenyl)-3-

phenylthiourea (21e). 896 mg (3.3 mmol) of HgCl₂ were added over a solution of 325 mg (3.0 mmol) of 1,4-phenylenediamine, 907 mg (3.0 mmol) of N,N'-di(tertbutoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in DMF (5 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 22 h more at room temperature. Then, the reaction mixture was diluted with EtOAc and filtered through a pad of Celite. The filter cake was rinsed with EtOAc. The organic phase was extracted with water (2 \times 30 mL), washed with brine (1 \times 30 mL), dried over anhydrous Na₂SO₄ and concentrated under vacuum to give a dark residue. This residue was dissolved in 10 mL of dry CH₂Cl₂ and 0.37 mL (3.0 mmol) of phenyl isothiocyanate were added under an inert atmosphere and at 0 °C. The mixture was allowed to reach room temperature and was stirred for 19 h. Then, the solvent was removed in vacuo and the new residue obtained was purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc (3:7) to yield 347 mg (22%) of 21e as a white solid; mp 118-120 °C; IR (nujol) v 3311 (NH), 1756, 1716, 1151 (CO, CN, CS) cm⁻¹; ¹H NMR (CDCl₃): δ 1.34 (s, 18H, (CH₃)₃), 3.82 (s, 4H, CH₂), 6.99 (d, 2H, J = 8.0 Hz, Ar), 7.16–7.25 (m, 3H, Ar), 7.30–7.42 (m, 4H, Ar), 7.89 (broad s, 1H, NH), 8.16 (broad s, 1H, NH); ¹³C NMR (CDCl₃): δ 27.8 ((CH₃)₃), 43.1 (CH₂), 82.9 (<u>C</u>(CH₃)₃), 122.2, 124.7, 125.9, 126.1, 128.8, 130.8, 137.8, 140.0 (Ar), 147.5, 149.8 (CO, CN), 179.8 (CS).

Trifluoroacetate salt of 1-(4-guanidinophenyl)-3-phenylthiourea (21a). A solution of 243 mg (0.5 mmol) of 21d in 20 mL of CH_2Cl_2 :TFA (1:1) was stirred at room temperature for 3 h. After that time, the solvent was eliminated under vacuum and cold water was added to generate a precipitate that was filtered, washed with 100 more mL

of cold water and dried to yield 197 mg (94%) of the pure trifluoroacetate salt as a white solid; mp 166–168 °C; MS (ESI⁺) *m/z* 286.1183 [M+H]⁺; ¹H NMR (CD₃OD): δ 7.16–7.28 (m, 3H, Ar), 7.31–7.47 (m, 4H, Ar), 7.53 (d, 2H, *J* = 7.5 Hz, Ar); ¹³C NMR (CD₃OD): δ 122.4, 123.6, 124.2, 124.6, 126.6, 129.9, 136.5, 136.9 (Ar), 158.4 (CN), 182.4 (CS); ¹⁹F NMR (CD₃OD): δ -78.97; Anal. (C₁₆H₁₆F₃N₅O₂S^{-1.0}H₂O) C, H, N.

Trifluoroacetate salt of 1-[4-(2-imidazolidinylimino)phenyl]-3-phenylthiourea (21b). A solution of 256 mg (0.5 mmol) of 21e in 20 mL of CH₂Cl₂:TFA (1:1) was stirred at room temperature for 3 h. After that time, the solvent was eliminated under vacuum and cold water was added to generate a precipitate that was filtered, washed with 100 more mL of cold water and dried to yield 221 mg (92%) of the pure trifluoroacetate salt as a yellow solid; mp 138–140 °C; MS (ESI⁺) *m/z* 312.1379 [M+H]⁺; ¹H NMR (D₂O): δ 3.72 (s, 4H, CH₂), 7.26–7.40 (m, 7H, Ar), 7.41–7.48 (m, 2H, Ar); ¹³C NMR (D₂O): δ 42.2 (CH₂), 124.7, 125.8, 127.1, 127.4, 129.1, 133.3, 136.3, 136.6 (Ar), 158.2 (CN), 179.4 (CS); ¹⁹F NMR (D₂O): δ -76.15; Anal. (C₁₈H₁₈F₃N₅O₂S³.0H₂O) C, H, N.

4-[2,3-di(*tert*-butoxycarbonyl)guanidino]benzanilide (22d). Method A with 896 mg (3.3 mmol) of HgCl₂, 637 mg (3.0 mmol) of 4-aminobenzanilide, 830 mg (3.0 mmol) of *N*,*N*'-di(*tert*-butoxycarbonyl)thiourea and 1.3 mL (9.3 mmol) of Et₃N in CH₂Cl₂:DMF (5:1) (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 22 h more at room temperature. The reaction was worked up and purified by silica gel column chromatography, eluting with hexane:EtOAc (2:1) to yield 1.015 g (74%) of **22d** as a white solid; mp > 300 °C; MS (ESI⁺) *m/z* 477.2269 [M+Na]⁺; IR (nujol, cm⁻¹) v 3375, 3187 (NH), 1718, 1658, 1643, 1596 (CO, CN); ¹H NMR (CDCl₃): δ 1.54 (s, 9H, (CH₃)₃), 1.57 (s, 9H, (CH₃)₃), 7.11–7.20 (m, 1H, Ar), 7.33–7.42 (m, 2H, Ar), 7.63–

7.78 (m, 4H, Ar), 7.80–7.93 (m, 2H, Ar), 8.08 (broad s, 1H, PhNHCOPh), 10.55 (broad s, 1H, NH_{Gu}), 11.65 (broad s, 1H, NH_{Gu}); ¹³C NMR (CDCl₃): δ 27.9, 28.0 ((CH₃)₃), 80.1, 84.1 (<u>C</u>(CH₃)₃), 120.1, 122.4, 124.1, 128.0, 128.8, 131.3, 138.4, 139.3 (Ar), 153.1, 153.8 ((CH₃)₃CO<u>C</u>O), 163.1 (CN), 165.6 (PhNH<u>C</u>OPh).

4-[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]benzanilide (22e). Method A with 896 mg (3.3 mmol) of HgCl₂, 637 mg (3.0 mmol) of 4-aminobenzanilide, 907 mg (3.0 mmol) of *N*,*N*'-di(*tert*-butoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in CH₂Cl₂:DMF (5:1) (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 25 h more at room temperature. The reaction was worked up and purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc (6:4). The residue obtained after the column was recrystallised from hexane:Et₂O (1:1) to yield 843 mg (58%) of **22e** as a white solid; mp 163–165 °C; IR (nujol) v 3338 (NH), 1737, 1707, 1670, 1637 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.34 (s, 18H, (CH₃)₃), 3.85 (s, 4H, CH₂), 7.03 (d, 2H, *J* = 8.5 Hz, Ar), 7.08–7.16 (m, 1H, Ar), 7.29–7.39 (m, 2H, Ar), 7.66 (d, 2H, *J* = 8.0 Hz, Ar), 7.80 (d, 2H, *J* = 8.5 Hz, Ar), 8.04 (broad s, 1H, NH); ¹³C NMR (CDCl₃): δ 27.8 ((CH₃)₃), 43.2 (CH₂), 83.0 (<u>C</u>(CH₃)₃), 120.0, 121.2, 123.9, 127.8, 128.1, 128.8, 138.3, 140.2 (Ar), 149.8 ((CH₃)₃CO<u>C</u>O), 151.9 (CN), 165.3 (PhNH<u>C</u>OPh).

Hydrochloride salt of 4-(2-imidazolidinylimino)benzanilide (22b). Following method B, 158 mg (94%) of the pure hydrochloride salt of 22b were obtained as a white solid; mp decomposes over 270 °C; MS (ESI⁺) m/z 281.1369 [M+H]⁺; ¹H NMR (D₂O): δ 3.71 (s, 4H, CH₂), 7.22–7.32 (m, 3H, Ar), 7.41–7.52 (m, 4H, Ar), 7.74–7.83

(m, 2H, Ar); ¹³C NMR (D₂O): δ 42.1 (CH₂), 121.7, 121.8, 125.3, 128.6, 128.7, 130.7, 136.3, 138.4 (Ar), 157.0 (CN), 167.3 (CO); Anal. (C₁₆H₁₇ClN₄O⁻1.0H₂O) C, H, N.

4'-[2,3-di(*tert*-butoxycarbonyl)guanidino]benzanilide (23d). Method A with 896 mg (3.3 mmol) of HgCl₂, 637 mg (3.0 mmol) of 4'-aminobenzanilide, 830 mg (3.0 mmol) of N,N'-di(*tert*-butoxycarbonyl)thiourea and 1.3 mL (9.3 mmol) of Et₃N in CH₂Cl₂:DMF (5:1) (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 22 h more at room temperature. The reaction was worked up and purified by silica gel column chromatography, eluting with hexane:EtOAc (3:1) to yield 850 mg (62%) of 23d as a white solid.

Method C: 0.28 mL (2.0 mmol) of Et₃N and 0.23 mL (2.0 mmol) of benzoyl chloride were added under an inert atmosphere and at 0 °C over a solution of 701 mg (2.0 mmol) of 4-[2,3-di(*tert*-butoxycarbonyl)guanidino]aniline **8** in dry CH₂Cl₂ (10 mL). The reaction mixture was allowed to reach room temperature and stirred for 16 h. Then, 20 more mL of CH₂Cl₂ were added and the organic phase was washed with water (2 × 15 mL) and dried over anhydrous Na₂SO₄. The solvent was removed *in vacuo* and the residue obtained was purified by silica gel column chromatography, eluting with hexane:EtOAc (3:1) to yield 820 mg (90%) of **23d** as a white solid; mp > 300 °C; MS (ESI⁺) *m/z* 477.2126 [M+Na]⁺; IR (nujol) v 3379, 3261, 3170 (NH), 1718, 1645, 1627, 1575 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.36 (s, 9H, (CH₃)₃), 1.57 (s, 9H, (CH₃)₃), 7.25 (d, 2H, *J* = 9.0 Hz, Ar), 7.38–7.52 (m, 3H, Ar), 7.56 (d, 2H, *J* = 8.5 Hz, Ar), 7.81 (d, 2H, *J* = 7.0 Hz, Ar), 8.74 (broad s, 1H, PhNHCOPh), 10.03 (broad s, 1H, NH_{Gu}), 11.50 (broad s, 1H, NH_{Gu}); ¹³C NMR (CDCl₃): δ 27.9, 28.0 ((CH₃)₃), 79.7, 83.7 (<u>C</u>(CH₃)₃), 120.7, 124.5, 127.1, 128.2, 131.6, 131.2, 135.5, 136.5 (Ar), 153.0, 154.8 ((CH₃)₃COCO), 163.1 (CN), 166.0 (PhNHCOPh). **4'-[1,3-di**(*tert*-butoxycarbonyl)-2-imidazolidinylimino]benzanilide (23e). Method A with 896 mg (3.3 mmol) of HgCl₂, 637 mg (3.0 mmol) of 4'-aminobenzanilide 23, 907 mg (3.0 mmol) of *N*,*N'*-di(*tert*-butoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in CH₂Cl₂:DMF (5:1) (6 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 25 h more at room temperature. The reaction was worked up and purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc (3:7). The residue obtained after the column was recrystallised from EtOAc to yield 697 mg (48%) of **23e** as a white solid; mp 115–117 °C; IR (nujol) v 3309 (NH), 1752, 1718, 1696 (CO, CN) cm⁻¹; ¹H NMR (DMSO–d₆): δ 1.30 (s, 18H, (CH₃)₃), 3.77 (s, 4H, CH₂), 6.85 (d, 2H, *J* = 8.5 Hz, Ar), 7.49–7.62 (m, 3H, Ar), 7.67 (d, 2H, *J* = 8.0 Hz, Ar), 7.98 (d, 2H, *J* = 7.0 Hz, Ar), 10.14 (broad s, 1H, NH); ¹³C NMR (DMSO–d₆): δ 28.8 ((CH₃)₃), 44.2 (CH₂), 82.7 (<u>C</u>(CH₃)₃), 122.0, 122.1, 128.9, 129.6, 132.6, 134.9, 136.4, 140.3 (Ar), 145.8 ((CH₃)₃CO<u>C</u>O), 151.0 (CN), 166.3 (PhNH<u>C</u>OPh).

Hydrochloride salt of 4'-(2-imidazolidinylimino)benzanilide (23b). Following method B, 157 mg (96%) of the pure hydrochloride salt of 23b were obtained as a white solid; mp decomposes over 180 °C; MS (ESI+) m/z 281.1369 [M+H]⁺; ¹H NMR (D₂O): δ 3.70 (s, 4H, CH₂), 7.23 (d, 2H, J = 8.6 Hz, Ar), 7.48–7.58 (m, 4H, Ar), 7.60–7.65 (m, 1H, Ar), 7.80 (d, 2H, J = 7.0 Hz, Ar); ¹³C NMR (D₂O): δ 42.1 (CH₂), 122.8, 124.2, 126.9, 128.3, 131.5, 132.0, 133.0, 135.4 (Ar), 158.0 (CN), 168.9 (CO); Anal. (C₁₆H₁₇ClN₄O·0.5H₂O) C, H, N.

4-[2,3-di(*tert*-butoxycarbonyl)guanidino]acetophenone (30d). Method A, with 896 mg (3.3 mmol) of HgCl₂, 406 mg (3.0 mmol) of 4-aminoacetophenone **30**, 830 mg (3.0 mmol) of *N*,*N*'-di(*tert*-butoxycarbonyl)thiourea and 1.3 mL (9.3 mmol) of Et₃N in DMF (5 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 41 h more at room temperature. The reaction was worked up and purified by silica gel column chromatography, eluting with hexane:EtOAc (3:1) to yield 943 mg (83%) of **30d** as a white solid; mp = decomposes over 176 °C; IR (nujol) v 3278, 3146 (NH), 1718, 1686, 1637, 1598 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.51 (s, 9H, (CH₃)₃), 1.53 (s, 9H, (CH₃)₃), 2.55 (s, 3H, CH₃), 7.74 (d, 2H, *J* = 8.5 Hz, Ar), 7.92 (d, 2H, *J* = 8.0 Hz, Ar), 10.56 (broad s, 1H, NH), 11.61 (broad s, 1H, NH); ¹³C NMR (CDCl₃): δ 26.3 (CH₃), 27.9, 28.0 ((CH₃)₃), 79.9, 84.0 (<u>C</u>(CH₃)₃), 121.0, 129.3, 132.9, 141.2 (Ar), 153.1 ((CH₃)₃CO<u>C</u>O), 163.1 (CN), 196.8 (CH₃<u>C</u>O).

4-[1,3-di(*tert*-butoxycarbonyl)-2-imidazolidinylimino]acetophenone (**30e**). Method A, with 896 mg (3.3 mmol) of HgCl₂, 406 mg (3.0 mmol) of 4-30, 907 of aminoacetophenone (3.0)mmol) *N*,*N*'-di(*tert*mg butoxycarbonyl)imidazolidine-2-thione and 1.3 mL (9.3 mmol) of Et₃N in DMF (5 mL) at 0 °C. The resulting mixture was stirred at 0 °C for 1 h and 25 h more at room temperature. The reaction was worked up and purified by neutral alumina column flash chromatography, eluting with hexane:EtOAc (3:2). The residue obtained after the column was precipitated with Et₂O and washed with cold hexane to yield 613 mg (50%) of **30e** as a white solid; mp 113–115 °C; IR (nujol) v 1744, 1705, 1670 (CO, CN) cm⁻¹; ¹H NMR (CDCl₃): δ 1.31 (s, 18H, (CH₃)₃), 2.53 (s, 3H, CH₃), 3.84 (s, 4H, CH₂), 6.99 (d, 2H, J = 8.0 Hz, Ar), 7.85 (d, 2H, J = 8.0 Hz, Ar); ¹³C NMR (CDCl₃): δ 26.3

(CH₃), 27.8 ((CH₃)₃), 43.2 (CH₂), 83.0 (<u>C</u>(CH₃)₃), 121.0, 129.4, 131.2, 140.2 (Ar), 149.8 ((CH₃)₃CO<u>C</u>O), 153.3 (CN), 197.1 (CH₃<u>C</u>O).

DNA binding assays. Thermal melting experiments were conducted with a Varian Cary 300 Bio spectrophotometer equipped with a 6x6 multicell temperature-controlled block. Temperature was monitored with a thermistor inserted into a 1-mL quartz curvet containing the same volume of water as in the sample cells. Absorbance changes at 260 nm were monitored from a range of 20 °C to 95 °C with a heating / cooling rate of 0.5 °C/min and a data collection rate of two points per °C. The poly(dA)•poly(dT) DNA polymer was purchased from Amersham Pharmacia Biotech Inc, NJ, USA (extinction coefficient $\varepsilon_{260} = 6000 \text{ cm}^{-1}\text{M}^{-1}$ base). A quartz cell with a 1-cm path length was filled with a 1-mL solution of DNA polymer or DNA–compound complex. The DNA polymer (40 µM base) and the compound solution (12 µM) were prepared in a low salt buffer (0.01 M [2-(N-morpholino)ethanesulfonic acid], 0.001 M disodium EDTA, adjusted to pH 6.25) so that a compound to DNA base ratio of 0.3 was obtained. This effectively saturates all minor groove binding sites for these compounds. The thermal melting temperatures of the duplex or duplex–compound complex obtained from the first derivative of the melting curves are reported.

Ferriprotoporphyrin IX biomineralisation inhibition test (FBIT). The FBIT was performed according to Deharo et al..¹⁶ In a 96-well plate were incubated at 37 °C for 18–24 h a mixture containing: 50 μ L of 0.5 mg/mL of haemin chloride (Sigma H 5533) freshly dissolved in DMSO, 100 μ L of 0.5 M sodium acetate buffer (pH 4.4) and 50 μ L of different concentrations of drug solution or 50 μ L of solvent (for control). The plate was centrifuged at 1600 × g for 5 min and the supernatant was discarded. The remaining

pellet was resuspended with 200 μ L of DMSO to eliminate unreacted haemin. Then, the plate was centrifuged once again and the supernatant similarly discarded. The precipitate (β -haematin), was dissolved in 150 μ L of 0.1 N NaOH and the absorbance was read at 405 nm with an ELISA reader (ELX 800 Biotech Instruments). The percentage of inhibition of ferriprotoporphyrin IX biomineralisation was calculated with the following equation:

Inhibition (%) = $100 \times [(Abs. control - Abs. drug)/ Abs. control]$

IC₅₀ values were determined using the TENDANCE function of Excel program.

In Vitro Activity against *T. brucei rhodesiense* STIB900. This trypanosoma strain was isolated in 1982 from a human patient in Tanzania. Minimum Essential Medium (50 µl) supplemented with 25 mM HEPES, 1g/L additional glucose, 1% MEM nonessential amino acids (100x), 0.2 mM 2-mercaptoethanol, 2mM Na-pyruvate, 0.1mM hypoxanthine and 15% heat inactivated horse serum was added to each well of a 96well microtiter plate. 3-fold serial drug dilutions were prepared in duplicate in the columns covering a range from 90 µg/mL to 0.123 µg/mL. Then 10⁴ bloodstream forms of *T. b. rhodesiense* STIB 900 in 50 µL was added to each well and the plate incubated at 37 °C under a 5% CO₂ atmosphere for 72 h. 10 µL of resazurin solution (12.5 mg resazurin dissolved in 100 mL distilled water) were then added to each well and incubation continued for a further 2–4 hours. Then the plates were read with a Spectramax Gemini XS microplate fluorometer (Molecular Devices Cooperation, Sunnyvale, CA, USA) using an excitation wave length of 536 nm and an emission wave length of 588 nm. Data were analyzed using the microplate reader software Softmax Pro (Molecular Devices Cooperation, Sunnyvale, CA, USA).

In Vitro Activity against *P. falciparum K1*. In vitro activity against erythrocytic stages of *P. falciparum* was determined using a ³H-hypoxanthine incorporation assay,

39

using the chloroquine and pyrimethamine resistant K1 strain and the standard drug chloroquine (Sigma C6628). Compounds were dissolved in DMSO at 10 mg/mL and added to parasite cultures incubated in RPMI 1640 medium without hypoxanthine, supplemented with HEPES (5.94 g/L), NaHCO₃ (2.1 g/L), neomycin (100 U/mL), Albumax (5 g/L) and washed human red cells A^+ at 2.5% haematocrit (0.3% parasitaemia). Serial doubling dilutions of each drug were prepared in 96-well microtiter plates and incubated in a humidified atmosphere at 37 °C; 4% CO₂, 3% O₂, 93% N₂. After 48 h 50 µL of ³H-hypoxanthine (= 0.5 µCi) was added to each well of the plate. The plates were incubated for a further 24 h under the same conditions. The plates were then harvested with a Betaplate cell harvester (Wallac, Zurich, Switzerland), and the red blood cells transferred onto a glass fibre filter then washed with distilled water. The dried filters were inserted into a plastic foil with 10 mL of scintillation fluid, and counted in a Betaplate liquid scintillation counter (Wallac, Zurich, Switzerland). IC₅₀ values were calculated from sigmoidal inhibition curves using Microsoft Excel.

In Vitro Cytotoxicity with L–6 cells. Assays were performed in 96-well microtiter plates, each well containing 100 μ L of RPMI 1640 medium supplemented with 1% L-glutamine (200 mM) and 10% fetal bovine serum, and 4 x 10⁴ L–6 cells (rat skeletal myoblasts) with or without a serial drug dilution columns covering a range from 90 μ g/mL to 0.123 μ g/mL. Each compound was tested in duplicate. After 72 h of incubation the plates were inspected under an inverted microscope to assure growth of the controls and sterile conditions. 10 μ L of Alamar Blue (12.5 mg resazurin in 100 mL phosphate buffered saline) was then added to each well and the plates incubated for another 2 h. Then the plates were read with a Spectramax Gemini XS microplate fluorometer (Molecular Devices Cooperation, Sunnyvale, CA, USA) using an excitation wave length of 536 nm and an emission wave length of 588 nm. Data were analysed

40

using the microplate reader software Softmax Pro (Molecular Devices Cooperation, Sunnyvale, CA, USA).

In Vivo Activity against *T. brucei*. All efficacy studies were approved by the institutional animal experimentation ethics committee. Female NMRI mice weighting 22–25 g were infected with cryopreserved stabilates of *T. brucei rhodesiense* STIB 900. Each mouse was infected intraperitoneally with 2×10^4 (STIB 900) bloodstream forms. Groups of four mice were treated intraperitoneally with the compounds on days 3, 4, 5, and 6. A control group remained untreated. The parasitemia of all animals was checked every second day up to day 14 post-infection and two times a week thereafter until 60 days. Death of animals was recorded to calculate the mean survival time. Surviving and aparasitemic mice were considered cured at 60 days and then euthanized.

In vivo antimalarial efficacy studies. All efficacy studies were approved by the institutional animal experimentation ethics committee. In vivo antimalarial activity was assessed basically as previously described.⁵¹ Groups of three female NMRI mice (20–22 g) intravenously infected with 2 x 10⁷ parasitized erythrocytes on day 0 with GFP-transfected *P. berghei* strain ANKA.⁵² Compounds were formulated in 100% DMSO, diluted 10-fold in distilled water and administered intraperitoneally in a volume of 10 mL kg⁻¹ on four consecutive days (4, 24, 48 and 72 h post infection). Parasitemia was determined on day 4 post infection (24h after last treatment) by FACS analysis. Activity was calculated as the difference between the mean per cent parasitaemia for the control (n = 5 mice) and treated groups expressed as a per cent relative to the control group. The survival time in days was also recorded up to 30 days after infection. A compound was considered curative if the animal survived to day 30 after infection with no detectable parasites.

Acknowledgments. We are grateful to the UNICEF/UNDP/World Bank/WHO Special Programme for Research and Training in Tropical Diseases (TDR) (RB), the CSIC–I3 program (PIE200680I121) and the Spanish Ministerio de Educación y Ciencia (SAF2006–04698) for funding. F.R. thanks the Consejería de Educación Cultura y Deporte de la Comunidad Autónoma de La Rioja for his Grant. Research on DNA interactions is supported by National Institutes of Health grant AI064200 (W.D.W.). We thank J.C. Janse, Leiden University, for providing the GFP transfected *P. berghei* strain (RB).
