Abstract: Two bioactive compounds, quercetin and ferulic acid, were encapsulated using the electrospinning technique within hybrid amaranth protein isolate (API):pullulan ultrathin fibres. Initially, the composition of the encapsulation structures was optimized, both in terms of matrix components ratio and to maximize the bioactive loading. The morphology and thermal stability of the developed encapsulation structures were evaluated, as well as the encapsulation efficiency and distribution within the fibres of both antioxidant compounds. Moreover, the release characteristics and protection ability of the encapsulation structures during an in-vitro digestion study were investigated. Smooth ultrathin electrospun fibres were obtained in which the antioxidants were homogeneously distributed. Through this methodology, it was possible to incorporate within the API:pullulan fibres up to 10 and 20 % (by weight) of quercetin and ferulic acid, respectively, which were released in a sustained manner during in-vitro digestion, keeping to a greater extent their antioxidant capacity in comparison with the non-encapsulated compounds.

## HIGHLIGHTS

- Quercetin and ferulic acid were encapsulated using electrospinning
- Blends of amaranth protein isolate and pullulan were used as encapsulating matrices
- Sustained release of the antioxidants from the electrospun fibers was observed
- Encapsulation improved antioxidant capacity of bioactives during *in-vitro* digestion

## Abstract

Two bioactive compounds, quercetin and ferulic acid, were encapsulated using the electrospinning technique within hybrid amaranth protein isolate (API):pullulan ultrathin fibres. Initially, the composition of the encapsulation structures was optimized, both in terms of matrix components ratio and to maximize the bioactive loading. The morphology and thermal stability of the developed encapsulation structures were evaluated, as well as the encapsulation efficiency and distribution within the fibres of both antioxidant compounds. Moreover, the release characteristics and protection ability of the encapsulation structures during an *in-vitro* digestion study were investigated. Smooth ultrathin electrospun fibres were obtained in which the antioxidants were homogeneously distributed. Through this methodology, it was possible to incorporate within the API:pullulan fibres up to 10 and 20 % (by weight) of quercetin and ferulic acid, respectively, which were released in a sustained manner during *in-vitro* digestion, keeping to a greater extent their antioxidant capacity in comparison with the non-encapsulated compounds.

## Keywords

Amaranth protein isolate, pullulan, encapsulation, electrospinning, quercetin, ferulic acid, *in-vitro* digestion, controlled release

## Chemical compounds studied in this article

Quercetin (PubChem CID: 5280343); Ferulic acid (PubChem CID: 445858)

## 1. Introduction

1  
2 Synthetic antioxidants are often used to preserve food quality, although natural  
3  
4 antioxidants like carotenoids, vitamins, flavonoids and phenolic acids act as a natural  
5  
6 defense in the organism to fight illnesses. In particular, food antioxidants have focused a  
7  
8 great deal of attention due to their potential to prevent certain diseases like cancer and  
9  
10 neurodegenerative or cardiovascular diseases (Giampieri, Alvarez-Suarez, & Battino,  
11  
12 2014; Mates, Segura, Alonso, & Marquez, 2011; Yang et al., 2013).

13  
14 Quercetin is a flavonoid naturally present in vegetables, fruits, non-alcoholic drinks and  
15  
16 medicinal plants. It is abundant in apples, onions, teas and red wines, where it is present  
17  
18 as a glucoside. Many health-related beneficial effects have been ascribed to quercetin,  
19  
20 including anti-inflammatory and antiallergic effects as well as having the potential to  
21  
22 diminish or prevent cardiovascular disease and certain types of cancer (Campbell et al.,  
23  
24 2006; Fawzy & Asker, 2009; Gupta et al., 2010; Makris & Rossiter, 2001). The  
25  
26 limitations for incorporating quercetin into functional foods are related to its low water  
27  
28 solubility, as well as its degradation when exposed to high temperature, oxygen and/or  
29  
30 light (Buchner et al., 2006; Scalia & Mezzena, 2009; Zenkevich et al., 2007).

31  
32 Furthermore, its low bioavailability as well as the chemical instability when exposed to  
33  
34 gastrointestinal track conditions, limits the biological activity and therefore the potential  
35  
36 health benefits.

37  
38 Ferulic acid is a hydroxycinnamic acid, with strong antioxidant properties. It is an  
39  
40 abundant phenolic compound found in plant cell walls, but it is barely present as a free  
41  
42 compound, but usually it is covalently bound to polysaccharides or proteins from the  
43  
44 cell walls. In its free form, ferulic acid is a potent antimicrobial compound (Jeong et al.,  
45  
46 2000) and has demonstrated to be a chemopreventive agent towards colon cancer  
47  
48 (Kawabata et al., 2000). Ferulic acid is FDA approved and, among other uses, it is  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 added as a preservation agent to inhibit autooxidation of oils (Graf, 1992). Its  
2 drawbacks for direct addition to functional foods are the photodegradation and  
3  
4 sensitivity to oxygen exposure.  
5  
6  
7

8  
9 Micro- and nanoencapsulation have been considered as plausible options for the  
10 protection of these antioxidant compounds (Braithwaite et al., 2014). For instance,  
11  
12 Scalia et al. (2009) demonstrated that incorporating quercetin within lipidic  
13  
14 microparticles effectively resulted in lower photodegradation of the bioactive. Similarly,  
15  
16 the development of nanoencapsulation systems based on cyclodextrins, liposomes and  
17  
18 quitosan have resulted efficient in improving the solubility, stability and bioavailability  
19  
20 of quercetin in pharmaceutical applications (Barras et al., 2009; Wu et al., 2008; Zhang  
21  
22 et al., 2007). Pool et al. (2012a & 2012b) developed PLGA and Eudragit nanoparticles  
23  
24 loaded with quercetin, proving that the antioxidant activity and the bioaccessibility  
25  
26 within simulated small intestinal conditions were enhanced when quercetin was  
27  
28 encapsulated. Quercetin has also been incorporated in nanoemulsion-based delivery  
29  
30 systems improving its bioaccessibility compared with crystalline quercetine (Pool et al.,  
31  
32 2013). Similarly, encapsulation systems for ferulic acid based on cyclodextrins, lipidic  
33  
34 nanoparticles, micelles, and microemulsions have been developed (Anselmi et al., 2008;  
35  
36 Carlotti et al., 2008).  
37  
38

39  
40 Regarding the encapsulation techniques, in the last years, electrospinning has been  
41  
42 broadly explored as a straightforward and versatile method, with a number of  
43  
44 advantages when compared to traditional encapsulation techniques such as spray drying,  
45  
46 coacervation or ionic gelation (Bhushani & Anandharamakrishnan, 2014; Zussman,  
47  
48 2011). In fact, this high-voltage-based technique has been recently used to develop  
49  
50 electrospun fibres containing quercetin (Li et al., 2014; Peng et al., 2011) and ferulic

1 acid (Yan et al., 2014; Yu et al., 2010). However, even though during the process of  
2 fibre formation is normally considered that the solvent is mostly evaporated, for food-  
3 related applications it is highly desired that food-derived matrices and food-approved  
4 solvents are used for encapsulation. Recently, we reported about the development of  
5 novel amaranth protein-based electrospun fibres using a food contact solvent (Aceituno-  
6 Medina et al., 2013). Amaranth is a traditional under-utilized Mexican crop with highly  
7 nutritious grains and leaves. The aim of this work was to investigate the potential of these  
8 novel amaranth-based structures for the encapsulation and protection of two potent  
9 antioxidant compounds (quercetin and ferulic acid) to be incorporated into functional  
10 foods. To the best of our knowledge, this is the first time that an amaranth protein-based  
11 matrix is used for the encapsulation and protection of bioactives. The morphology of the  
12 developed electrospun fibres together with the encapsulation efficiency and bioactive  
13 stability and distribution within the fibres were studied. Moreover, the release profile  
14 and antioxidant capacity of the encapsulated functional substances during an *in-vitro*  
15 digestion study were also investigated and compared to that of the free compounds.

## 39 **2. Materials and methods**

### 40 **2.1 Materials**

41 Formic acid of 95% purity, the non-ionic surfactant polyoxyethylene sorbitan  
42 monooleate (Tween 80), quercetin, ferulic acid (99.98% of purity), 2,2'-azino-bis(3-  
43 ethylbenzothiazoline-6-sulphonic acid) (ABTS), potassium persulphate and pullulan  
44 ( $M_w \sim 100,000$  Da) were supplied by Sigma-Aldrich (St. Louis, MO, USA). All products  
45 were used as received, without further purification. The commercial amaranth protein  
46 concentrate (*Amaranthus hypochondriacus* L. Revancha variety) was supplied by  
47 Nutrisol (Hidalgo, Mexico). The Amaranth Protein Isolate (API) was prepared based on

1 the methodology previously reported by Martínez and Añón (1996) with some  
2 modifications. The protein isolate prepared under these conditions consisted in a  
3  
4 mixture of different proteins with molecular weights ranging from 10-83 kDa  
5  
6 (Aceituno-Medina et al., 2013). Briefly, the commercial amaranth protein concentrate  
7  
8 (APC) was defatted with hexane for 12 h (10% (w/v) suspension). Then, the amaranth  
9  
10 protein concentrate was suspended in water and its pH was adjusted to 9 with a 2 M  
11  
12 NaOH solution. The suspension was stirred for 30 min at room temperature and, then,  
13  
14 centrifuged 20 min at 9000 g. Then, the supernatant was adjusted to pH 5 with 2 M HCl  
15  
16 and centrifuged at 9000 g for 20 min at 4°C. The pellet was resuspended in water,  
17  
18 neutralized with 0.1 N NaOH and freeze-dried. The protein content was determined by  
19  
20 the Kjeldahl technique (AOAC, 1996) using a conversion factor of 5.85.

## 29 **2.2 Preparation of bioactive-containing solutions for electrospinning**

30  
31 In order to develop the electrospun fibres for encapsulation of the bioactives, blends of  
32  
33 50:50 (w/w) and 80:20 (w/w) API:pullulan blends with the surfactant Tween 80 (~20 %  
34  
35 by weight with respect to the API content) were prepared using 95% formic acid as the  
36  
37 solvent. The polymer content in solution was kept constant at 20% (w/v). The bioactives  
38  
39 were incorporated in the solutions at 10 % (w/w) in the case of quercetin and 20%  
40  
41 (w/w) in the case of ferulic acid with respect to the biopolymer blend weight. The  
42  
43 solutions were gently stirred until homogeneous dispersions were obtained.  
44  
45  
46  
47  
48  
49  
50

## 51 **2.3 Characterization of the polymer solutions**

52  
53 The apparent viscosity ( $\eta_a$ ) of the polymeric solutions at  $100 \text{ s}^{-1}$  was determined using a  
54  
55 rotational viscosity meter Visco Basic Plus L from Fungilab S.A. (San Feliu de  
56

#### 7 **2.4 Development of encapsulation structures through electrospinning**

8  
9 The methodology to obtain API/pullulan fibres through electrospinning has been  
10 described elsewhere (Aceituno-Medina et al., 2013). All of the electrospinning  
11 experiments were carried out at room temperature in air. The electrospinning  
12 environmental conditions were maintained stable at 24°C and 60% RH by having the  
13 equipment enclosed in a specific chamber with temperature and humidity control. In  
14 this work, the specific conditions of the electrospinning process for obtaining the fibres  
15 loaded with the bioactives were: a tip-to-collector distance of 10 cm, a flow rate of the  
16 solution of 0.4 ml/h and the voltage was kept at 22 kV.

#### 31 **2.5 Optical and Scanning Electron Microscopy (SEM)**

32 The presence and distribution of the bioactives within the electrospun API/pullulan  
33 fibres were observed using a digital microscopy system (Nikon Eclipse 90i, Barcelona,  
34 Spain) fitted with a 12 V, 100 W halogen lamp and equipped with a digital imaging  
35 head which integrates an epifluorescence illuminator. A digital camera head (Nikon DS-  
36 5Mc) with a 5 megapixel CCD cooled with a Peltier mechanism was attached to the  
37 microscope. Nis Elements software (Nikon Instruments Inc., Melville, NY, USA) was  
38 used for image capturing and the Adobe Photoshop CS3 extended software was used for  
39 image processing and analysis.

53 The morphology of the bioactive-containing electrospun fibres was examined using  
54 SEM (Hitachi S-4100) after sputtering the samples with a gold–palladium mixture  
55 under vacuum. All SEM experiments were carried out at an accelerating voltage of 10

## 6 **2.6 Raman microspectroscopy**

7  
8  
9 The dispersion of the bioactives within the electrospun fibres were analyzed using  
10 Raman microspectroscopy. Raman images were taken with a Jasco NRS-3100 Confocal  
11 Micro- Raman spectrophotometer (Jasco Inc., Easton, MD, USA) using a short working  
12 distance 100x objective. The laser source used was a NIR excitation tuned at 785 nm to  
13 avoid excessive fluorescence in the Raman signal. Raman chemical images were carried  
14 out in the point by point mode by plotting the areas of the quercetin and ferulic acid  
15 bands at  $\sim 1322$  and  $\sim 1606$   $\text{cm}^{-1}$ , respectively, and were constructed by taking 25 x 25  
16 spectra equally spaced along the selected fibre sample area. Both bioactives are good  
17 Raman scatterers and, thus, very short acquisition times (i.e. 2-3 s) were needed to  
18 record intense spectra, which only showed the signal of the antioxidants within the  
19 electrospun fibres.

## 39 **2.7 Encapsulation efficiency**

40  
41 To assess the bioactive encapsulation yield, approximately 3 mg of loaded fibres were  
42 placed in a Falcon tube with 5 ml of ethanol and stirred during 10 min at 300 rpm to  
43 remove the bioactive from the surface of the encapsulation structures. Then, the tubes  
44 were centrifuged at  $\sim 10000$  g during 10 min at 20°C. The supernatant was taken and  
45 stored for subsequent analysis and the precipitate was repeatedly resuspended in 5 ml of  
46 ethanol and centrifuged as explained above until no signal from the bioactive was  
47 obtained. The amount of quercetin and ferulic acid was monitored through UV-Vis  
48 spectrophotometry using a SP-2000UV spectrophotometer, through interpolation of the

absorbance maximum at 256 nm and 324 nm for quercetin and ferulic acid, respectively, within the calibration curves previously obtained.

## 2.8 Thermogravimetric Analysis (TGA)

Thermogravimetric analysis (TG) curves were recorded with a TGA-DTA Setaram Setsys equipment. The samples (ca. 10 mg) were heated from 50 to 800°C with a heating rate of 5°C/min under argon atmosphere.

## 2.9 Release kinetics during *in-vitro* digestion

The *in-vitro* digestion studies were carried out following the methodology proposed by Dinnella et al. (2007). For the gastric digestion, 4mg of fibres (10 tubes with 4 mg of sample each) were diluted with 5 ml of distilled water and acidified to pH 2 using 6M HCl under constant stirring. Later on, 0.6 ml of a porcine pepsin solution (160 mg/ml) in 0.1 M HCl were added to the previous solution; distilled water was added to reach a final volume of 10 ml. The mixture was protected from light and stirred for 2h at 37°C. At different time intervals (10, 30, 60, 90 and 120 min) the amount of released bioactive was analyzed through UV-Vis spectrophotometry. The amount of released bioactive was calculated from the previously developed calibration curve. After gastric digestion, the pH of the digesta was increased to pH 5 with 0.045 M NaHCO<sub>3</sub> and 2.4 ml of pancreatin–bile solution (pancreatin 4 mg/ml, bile 25 mg/ml in 0.1 M NaHCO<sub>3</sub>) were added. Then, the pH was increased to 7.0 with 0.005 M NaHCO<sub>3</sub>, and the mixture, protected from light, was stirred at 37 °C for 2 h. Similarly as in the gastric stage, the released bioactive was analyzed at different time intervals (10, 30, 60, 90 and 120 min) through UV-Vis spectrophotometry following the same methodology as described above.

## 2.10 Antioxidant activity during *in-vitro* digestion

The antioxidant activity was quantified along the digestion process to assess the protective effect of the encapsulation structures developed. The antioxidant capacity was determined using the ABTS<sup>•+</sup> radical cation method (Re et al., 1999) using Trolox in methanol as a standard. The measurements were carried out at 734 nm using a 96 well microplate reader (Molecular Devices Inc, Sunnyvale, CA, U.S.A.). Results are expressed as mmol Trolox equivalent antioxidant activity/g of bioactive.

The *in-vitro* digestion process was carried out following the same methodology as above, but in this case, 20 mg of fibres and the equivalent amount of free bioactive solubilized in ethanol were used. The methanolic extracts obtained after the gastric and intestinal stages were homogenized and 20 µl of these solutions were added to 230 µl of the ABTS<sup>•+</sup> solution (absorbance of 0.7± 0.02).

The inhibition percentages were calculated using equation 1. A decrease in the characteristic blue colour of the radical ABTS<sup>•+</sup> upon bioactive reaction provides a measurement of the capacity that this compound has to stabilize the radical. This change in colour is indicated by a decrease in the absorbance maximum at 734 nm:

$$\% \text{ inhibition} = [(Abs \text{ control} - Abs \text{ sample}) / Abs \text{ control}] * 100 \text{ (Eq. 1)}$$

The equivalent Trolox antioxidant capacity (TEAC) of the different compounds after the *in-vitro* gastric and intestinal digestion processes was calculated taking into account, both the bioactive content of the fibres and the release percentage at the end of the gastric and intestinal digestion stages.

### 3. RESULTS AND DISCUSSION

#### 3.1 Morphology of the encapsulation structures and distribution of the bioactives within the fibres

In a previous work, electrospun fibres made of an amaranth protein isolate (API) and pullulan in different concentrations were developed and it was found that up to 80% (w/w) API content, when the surfactant Tween 80 (~20 % by weight with respect to the API content) was added, continuous and relatively homogeneous fibres were obtained (Aceituno-Medina et al., 2013). Initially, the effect of bioactive incorporation within the electrospun fibres was studied and related to the viscosity of the initial solutions. The amount of bioactive that could be added to the electrospinning solutions giving raise to stable suspensions and, thus, to a continuous fibre production process was first optimized. Regarding quercetin incorporation, only the solutions with the composition 50:50 API:pullulan (w/w) were suitable for stable electrospinning with a maximum bioactive content of 10 % by weight with respect to the biopolymer blend weight. In the case of ferulic acid, it was possible to incorporate this antioxidant within the fibres with more API content, i.e. in the 80:20 (w/w) API:pullulan structures, and the maximum loading attained was 20 % (w/w). Greater loadings resulted in precipitation of ferulic acid. Therefore, these two compositions were selected for subsequent analysis.

As observed in Figure 1, addition of quercetin to the API:pullulan fibres did not significantly modify the viscosity of the solution, but resulted in average thinner diameters of the electrospun fibres. This result indicates that, probably, addition of quercetin resulted in increased conductivity of the solution, which is known to affect the whipping motion of the electrospinning jet, thus, leading to thinner fibres (Bhardwaj & Kundu, 2010). In the case of ferulic acid addition, a slight increase in solution viscosity

1 was observed, which is usually related to thicker fibre morphologies (Suwatong et al.,  
2 2007). In general, for both encapsulation structures, smooth and defect-free fibres were  
3  
4 obtained, confirming that no phase separation occurred during the electrospinning  
5  
6 process and suggesting a good dispersion of the bioactives.

12 INSERT FIGURE 1 ABOUT HERE  
13  
14  
15

16  
17 In order to confirm the effective encapsulation of the antioxidants, fluorescence optical  
18  
19 microscopy was carried out. Quercetin is known to have an emission fluorescence  
20  
21 wavelength between 500 and 600 nm (Ram et al., 2004; Sengupta y Sengupta, 2003),  
22  
23 while ferulic acid exhibits an emission at approximately 425 nm (Ram et al., 2004) and,  
24  
25 thus, this property was used to visually check the inclusion of the antioxidants within  
26  
27 the electrospun structures. Figure 1 also shows the fluorescence images of the  
28  
29 API:pullulan fibres containing both bioactives which, as observed, seemed to be well  
30  
31 distributed along the fibres.  
32  
33  
34  
35

36 Raman spectroscopy was also used to evaluate, not only the distribution, but also the  
37  
38 stability of the encapsulated compounds. First, the Raman spectra of both compounds  
39  
40 was obtained, so as to identify the characteristic vibrational bands with the aim to  
41  
42 construct the Raman images from the confocal microscopy images taken from the  
43  
44 samples. Figure 2 shows both the individual Raman spectra from the bioactives and the  
45  
46 corresponding confocal Raman images from the API:pullulan electrospun fibres  
47  
48 containing the antioxidants, which were obtained considering the area of the  
49  
50 characteristic vibrational bands from quercetin and ferulic acid at  $\sim 1322\text{ cm}^{-1}$  and  $\sim 1606$   
51  
52  $\text{cm}^{-1}$ , respectively.

INSERT FIGURE 2 ABOUT HERE

1  
2  
3  
4 The Raman images confirmed that as inferred from the fluorescence microscopy  
5 images, the bioactives were evenly distributed along the fibres. From Figure 2 it seems  
6 that some agglomeration areas were present in the quercetin-containing structures, fact  
7 that could be also observed in the fluorescence image (cf. Figure 1E). However, no  
8 displacements were observed in the vibrational bands from the individual spectra taken  
9 from the Raman images, indicating that the encapsulation process itself did not affect  
10 the stability of the bioactive compounds. It is interesting to note that even in the image  
11 points of lower intensity (indicated in the Raman images as F and G for the quercetin  
12 and ferulic acid structures, respectively), some characteristic bands from the  
13 antioxidants could be discerned, again highlighting the good dispersion of the bioactives  
14 within the encapsulates.

### 3.2 Encapsulation efficiency

31  
32  
33 To evaluate the encapsulation efficiency, calibration curves from both antioxidants in  
34 ethanol were prepared. The amount of quercetin and ferulic acid within the developed  
35 API:pullulan electrospun fibres was then monitored through UV-Vis spectrophotometry  
36 through interpolation of the absorbance maximum at 256 and 324 nm for quercetin and  
37 ferulic acid, respectively, within the calibration curves previously obtained. Both the  
38 equations for the calibration curves and the encapsulation efficiency are compiled in  
39 Table 1.

INSERT TABLE 1 ABOUT HERE

1 From this table it can be observed that very good encapsulation yields were obtained for  
2 both bioactives in comparison with other encapsulation technologies (Barras et al.,  
3  
4 2009; Zhang et al., 2008). The efficiency obtained for quercetin was higher, but it  
5  
6 should be taken into account that the concentration of bioactive in this case was half the  
7  
8 concentration of ferulic acid used.  
9  
10

### 11 12 13 14 3.3 Thermal stability of the encapsulation structures 15

16 Thermogravimetric analysis of the loaded encapsulation structures was carried out to  
17  
18 investigate if the encapsulation process affected the thermal stability of both the  
19  
20 antioxidants and the matrices. Table 2 summarizes the main results and includes the  
21  
22 data for the bioactives alone and for the encapsulation structures without the bioactives  
23  
24 for comparison purposes. Pure quercetin displayed two main degradation events with  
25  
26 maximums at ca. 91°C and 358°C. The first one is related to water loss of the  
27  
28 compound, which disappeared upon encapsulation. The temperature of the second  
29  
30 degradation peak, which corresponds to the degradation temperature of this flavonoid,  
31  
32 significantly decreased upon encapsulation down to 220°C, probably due to the  
33  
34 dissolution/dispersion of the bioactive before encapsulation. Similar results of decreased  
35  
36 thermal stability were observed upon complexation of quercetin with gelatinized starch  
37  
38 (Zhang et al., 2011). However, it should be noted that the degradation temperature  
39  
40 within the capsules is still far from the usual temperatures used for food processing.  
41

46  
47  
48  
49  
50

51 INSERT TABLE 2 ABOUT HERE  
52  
53  
54

55 Regarding ferulic acid, a single degradation event was seen for the pure compound at  
56  
57 ~210°C. In a similar way as with quercetin, upon encapsulation within the electrospun  
58  
59  
60  
61  
62  
63  
64  
65

1 fibres, the degradation peak maximum temperature decreased to 177°C. The other two  
2 degradation peaks observed when plotting the weight loss first derivate from the TGA  
3 curves of the encapsulation structures at ~300 and ~400°C corresponded to the  
4  
5 curves of the encapsulation structures at ~300 and ~400°C corresponded to the  
6  
7 degradation of the API:pullulan blend and to the surfactant Tween 80, respectively  
8  
9 (Aceituno-Medina et al., 2013). When comparing these maximums with those from the  
10  
11 structures without bioactive, a slight decrease in the degradation temperature from the  
12  
13 biopolymer blend was observed, while the degradation temperature of the surfactant  
14  
15 remained almost unchanged (cf. Table 2).  
16

#### 22 3.4 Release kinetics of the bioactives during *in-vitro* digestion

23  
24 It is important to understand how the bioactives are released from the encapsulation  
25  
26 structures during the process of digestion along the gastrointestinal (GI) tract when  
27  
28 exposed to different pH conditions and to the presence of enzymes. It has been reported  
29  
30 that micro and nanostructured systems as well as hydrogels shrink in gastric conditions  
31  
32 while they swell under intestinal conditions, fact that conditions the release of the  
33  
34 encapsulated bioactive substances (Chen et al., 2004; Hoad et al., 2009; Rayment et al.,  
35  
36 2009).  
37  
38  
39  
40

41 In this work, following the *in-vitro* digestion methodology proposed by Dinnella et al.  
42  
43 (2007), the amount of bioactives released from the API:pullulan structures during this  
44  
45 simulated process was quantified.  
46  
47

48 Figure 3 shows the release profiles for quercetin and ferulic acid. It can be observed that  
49  
50 in the first 10 min of gastric digestion, ~22 and ~15% of quercetin and ferulic acid,  
51  
52 respectively, were released from the electrospun fibres, which probably corresponded to  
53  
54 the bioactive molecules closer to the fibre surface. These release mechanisms have been  
55  
56 already described for sorgo and maize proteins (Taylor et al., 2009; Wang et al., 2005)  
57  
58  
59  
60  
61  
62  
63  
64  
65

and are also related to the high specific surface of the ultrathin encapsulation structures.

A sustained release of quercetin from the electrospun encapsulation structures was observed during the gastric stage, releasing ~52% of the total compound.

Comparatively, the release of ferulic acid during the gastric stage was quicker and almost 60% of the antioxidant was released in only 30 min. Yu et al. (2010) incorporated ferulic acid in polyvinyl pyrrolidone nanofibres adding SDS as anionic surfactant and quantified the release in PBS medium. They observed a complete release of the bioactive in the first 10 min and, thus, when comparing with the present results, a considerable improvement in the release characteristics was observed using the API:pullulan structures.

INSERT FIGURE 3 ABOUT HERE

At the beginning of the intestinal *in-vitro* digestion process, another quick increase in the release profiles was observed for both bioactives (~19 and ~21% in the quercetin and ferulic acid release, respectively), which could be ascribed to the change in pH which probably affected the conformation of the amaranth protein encapsulating matrix, facilitating the release of the antioxidant s. Similar results have been reported for catechins encapsulated in protein-based matrices (Taylor et al., 2009). At the end of the *in-vitro* intestinal digestion stage, the amount of quercetin and ferulic acid released corresponded to 82 and 99% of the total content within the fibres, respectively.

In general, a more sustained release of quercetin was observed, which was probably related not only to the different composition of the fibres (i.e. ratio between API and pullulan and bioactive concentration), but also to the interactions of the bioactives themselves with the encapsulating matrices.

### 3.5 Antioxidant capacity of encapsulated vs. free bioactives during *in-vitro* digestion

It is well-known that pH and exposure to light, oxygen and temperature, may diminish the antioxidant activity of nutraceutical compounds (Liang y Subirade, 2010; Sansone et al., 2011; Anselmi et al., 2008; Carlotti et al., 2008; Fernández et al., 2009). However, little is known about how this antioxidant activity is kept during the digestion process.

Therefore, a further aim of the present study was to evaluate the antioxidant activity of the encapsulated bioactives after the *in-vitro* digestion study and to compare it with that from the non-encapsulated compounds. The ABTS<sup>•+</sup> method has been widely employed for evaluation of the antioxidant activity of biological materials, pure compounds and plant extracts both from hydrophilic and lipophilic nature. The inhibition percentage represents the loss of blue-green colour of the radical ABTS<sup>•+</sup>, upon addition of the antioxidant, thus decreasing the absorbance values measured at 734 nm. The control samples used to evaluate the antioxidant activity loss were freshly prepared methanolic extracts of the bioactives at the same concentrations than those found in the fibres.

Moreover, the antioxidant activity of the pure fibres (without bioactive) and of the enzymes employed in the *in-vitro* digestion process were also analysed, so as to check if they also contributed to the antioxidant activity recorded.

For the calibration curve, different concentrations of Trolox were prepared (from 50 to 800 mM) and the inhibition percentage for each of the concentrations was calculated, obtaining the following calibration curve equation:

$$y = 25.176x + 3.9357 \quad R^2 = 0.9925 \quad (\text{Eq. 2})$$

1 The equivalent Trolox antioxidant capacity (TEAC) of the different compounds after  
2 the *in-vitro* gastric and intestinal digestion processes was calculated and the results are  
3  
4 compiled in Table 3.  
5  
6  
7  
8

9  
10 INSERT TABLE 3 ABOUT HERE  
11  
12  
13

14 It is important to highlight that the TEAC for the encapsulated bioactives was calculated  
15 taking into account, both the bioactive content of the fibres and the release percentage at  
16 the end of the gastric and intestinal digestion stages. As commented on above, initially,  
17 the antioxidant capacity of the pure bioactives was evaluated, providing inhibition  
18 percentages of ~48.12 and ~52.17% for the quercetin and ferulic acid, respectively.  
19  
20  
21

22 From Table 3, it can be observed that the inhibition percentage obtained from the neat  
23 fibres and the enzymes used in the *in-vitro* digestion process was low in comparison  
24 with that from the bioactives, indicating that they did not have a relevant antioxidant  
25 capacity. Nevertheless, the obtained values were subtracted from their respective  
26 systems, so as not to overestimate the antioxidant capacity of both the free and  
27 encapsulated bioactives. From these corrected values in Table 3, it is clearly observed  
28 that the conditions used during the *in-vitro* digestion process, effectively affected the  
29 antioxidant capacity of the non-encapsulated bioactives and more than 60 and 70% of  
30 the initial inhibition percentage obtained for the quercetin and ferulic acid, respectively,  
31 was loss at the end of the digestion process. In contrast, encapsulation of the bioactives  
32 within the API:pullulan electrospun encapsulation structures resulted in an effective  
33 protection for the antioxidant capacity, showing inhibition percentajes of the radical  
34 ABTS<sup>•+</sup> which doubled those from the non-encapsulated compounds. These results are  
35 promising since they show the ability of these API:pullulan fibres to protect quercetin

5

#### 6 7 **4. CONCLUSIONS**

8  
9 Quercetin and ferulic acid were properly encapsulated within amaranth protein isolate  
10 (API):pullulan ultrathin fibres using the electrospinning technique. The composition of  
11 the fibres was optimized and smooth, defect free encapsulation structures were obtained  
12 which contained the antioxidants evenly distributed along the fibres. The thermal  
13 stability of the bioactives decreased upon encapsulation, probably due to the  
14 dissolution/dispersion of the antioxidants required for subsequent electrospinning.  
15  
16 However, a sustained release of quercetin and ferulic acid from the API:pullulan  
17 electrospun fibres was observed during *in-vitro* digestion, fact which contributed to  
18 improved antioxidant capacity of the bioactives in comparison with the free compounds.  
19  
20 Therefore, the developed electrospun structures show promisory results in terms of  
21 bioactive protection for application in functional foods.

**Table 1.** UV-Vis calibration curve equations and encapsulation efficiencies for quercetin and ferulic acid incorporated within 50:50 and 80:20 Amaranth Protein Isolate:pullulan electrospun fibers, respectively.

<b>Bioactive</b>	<b>Wt.%</b>	<b>Calibration curve equation</b>	<b>Theoretical concentration (µg bioactive/mg fiber)</b>	<b>Real concentration (µg bioactive/mg fiber)</b>	<b>Encapsulation efficiency (%)</b>
Quercetin	10	$y = 0.0072x + 0.0211$ $R^2 = 0.988$	83.3	$78.1 \pm 0.1$	$93.6 \pm 0.1$
Ferulic acid	20	$y = 0.0090x + 0.0014$ $R^2 = 0.998$	147.1	$123.1 \pm 0.2$	$83.7 \pm 0.1$

**Table 2.** TGA maximums of the weight loss first derivative (TD) for the different encapsulation structures

<b>Bioactive</b>	<b>API:pullulan (bioactive)</b>	<b>T<sub>max1</sub> (°C)</b>	<b>T<sub>max2</sub> (°C)</b>	<b>T<sub>max3</sub> (°C)</b>
-	50:50 -*		306.9	401.1
	80:20 -*		310.9	407.3
<b>Quercetin</b>	- (100%)	90.9	357.8	
	50:50 (10%)	220.6	298.6	403.4
<b>Ferulic acid</b>	- (100%)	210.7		
	80:20 (20%)	177.26	306.8	406.3

**Table 3.** Inhibition % of the ABTS radical and Trolox equivalent antioxidant capacity (TEAC) for the electrospun fibers, pure bioactives and enzymes studied after *in-vitro* gastric and intestinal digestion.

Sample	Gastric Conditions		Intestinal Conditions	
	Inhibition %	TEAC (mmol Trolox/g bioactive)	Inhibition %	TEAC (mmol Trolox/g bioactive)
API:pullulan 50:50	3.52 ± 0.03	-	4.85 ± 0.03	-
API:pullulan 80:20	5.09 ± 0.01	-	8.98 ± 0.01	-
Quercetin	13.39 ± 0.01	4.65 ± 0.01	16.62 ± 0.04	7.90 ± 0.02
API:pullulan (Quercetin)	30.12 ± 0.26	24.56 ± 0.24	31.06 ± 0.12	19.63 ± 0.09
Ferulic acid	17.56 ± 0.15	3.87 ± 0.04	14.96 ± 0.09	3.96 ± 0.03
API:pullulan (Ferulic acid)	37.69 ± 0.67	15.16 ± 0.30	33.89 ± 0.20	10.43 ± 0.71
Enzymes	2.56 ± 0.01	-	8.41 ± 0.01	-

## Figure Captions

**Figure 1.** SEM (A-D) and fluorescence microscopy (E,F) images of: 50:50 (A, C, E) and 80:20 (B,D,F) API:pullulan fibers without bioactive (A, B) and containing 10wt.% quercetin (C, E) and 20wt.% ferulic acid (D,F). Scale markers correspond to 1  $\mu\text{m}$  (C), 2 $\mu\text{m}$  (A, B, D) and 10  $\mu\text{m}$  (E, F). SEM micrographs include the apparent viscosity ( $\eta_{\text{app}}$ ) of the solutions and average diameter of the fibers obtained.

**Figure 2.** Individual Raman spectra of pure quercetin (A) and ferulic acid (B) and confocal Raman images of API:pullulan electrospun fibers containing quercetin (C) and ferulic acid (D) with the corresponding individual Raman spectra defined in the images as E, F, G and H.

**Figure 3.** Release kinetics of (A) quercetin and (B) ferulic acid from the API:pullulan fibers during an *in-vitro* digestion study.
